CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Catarrh (Gr. *katarreo*, 'I flow down'), a disease of great frequency in temperate latitudes, especially in changeable moist climates in the winter season. From its well-known connection with sudden falls of temperature, and other epidemic or atmospheric causes (see INFLU-

ENZA), as also from the chill often experienced at the commencement of the disease, it is popularly called a *cold*—a term, however, perhaps somewhat less definite in its meaning than catarrh, which word is usually restricted to the case of a cold affecting the chest, and attended with discharge of mucus by coughing. A 'cold in the head' is termed, in strict scientific language, *Coryza*: we shall, however, keep both forms in view in the present article. Catarrh, or cold, commonly begins with a feeling of chilliness, which may or may not be attributable to external causes. Sometimes this is absent, there being only a sense of languor and indisposition; not unfrequently there is no sensation of an unusual kind, until a stuffing is experienced in the nostrils, or severe headache, or hoarseness with cough, or oppression of the breathing. It most commonly attacks the nostrils first, and afterwards the air-passages leading to the chest. But the mucous membranes of the eyes and mouth are often affected, as well as those of the nose, throat, and lungs; and the disease may begin in any of these situations, and either spread to them all or leave one or more unaffected. When it habitually attacks the chest, without running through its ordinary course as indicated above, there is often some special cause of delicacy in the lungs, or some constitutional tendency towards Consumption (q.v.). The affected mucous membrane is at first abnormally red and swollen, and its secretion diminished. But it soon begins to pour out a discharge, at first watery, but afterwards glairy and of a yellowish colour, or purulent. The early stages of the disease are attended by considerable

irritation of the surfaces affected, and probably no one of the little miseries of life is more prostrating and discouraging for the time than a bad cold in the head. The tendency of catarrh to attack the chest, and thus to pass into Bronchitis (q.v.) or Pneumonia (q.v.), or to lay the foundation of tubercular disease, constitutes almost its only danger.

The treatment of a cold is commonly a simple matter, so far as the particular attack is concerned. But so many colds disappear in a little time without any special treatment that few persons, unless in delicate health, are willing to subject themselves to the confinement which is necessary to give any form of treatment a chance of success. In the earliest stage a warm hip or foot bath, and a large opiate (Dover's powder especially) at bedtime, if followed by confinement to the house, and, in severe cases, to bed or to the sofa for a day or two, light farinaceous diet, and, if the stomach and bowels are at all loaded, a dose or two of some gentle laxative, will generally cut short the disease. In some persons it yields readily and quickly to spirit of camphor, five drops on a lump of sugar every half-hour; but in others no effect is produced. Free bathing of the nose with hot water may relieve the irritability and discharge. In most cases frequent sipping of warm soothing drinks—gruel, barley-water, black-currant tea, &c.—is grateful to the patient; sometimes ice gives more relief. Some persons cure their colds by entire abstinence from food, and as much as possible from drink; others by spirit of mindererus and paregoric; some even profess to carry out the popular maxim, 'stuff a cold, and starve a fever,' and maintain that a good dinner and a tumbler of whisky or brandy toddy are the best specifics. That colds get well under all these methods need not be denied; but multiplied experience has shown that 'stuffing a cold' at its commencement is by no means to be commended. In the later stages, however, a more liberal diet than at first, and in some cases even a moderate allowance of

stimulants, affords considerable relief from the feeling of depression that remains for a time on the subsidence of a catarrh. The tendency to this disease, when habitual, and when not dependent on any form of constitutional disorder requiring special means for its cure, is best met by the daily use of the cold bath, with frequent exercise in the open air, and proper ventilation of the sleeping-apartment; also by friction of the skin, and by clothing which, without being oppressive, is comfortably warm. Exposure to draughts or sudden chills when the surface is perspiring is to be avoided; but a close confined air habitually breathed in a workshop or bedroom is a fruitful predisposing cause of the disease.

Catarrh or catarrhal inflammation is also used in modern pathology of an inflammation with the characters above described in any mucous membrane whatever; we have, for example, catarrh of the stomach, intestines, bladder, &c.

Catarrhini. Old-World monkeys, with a narrow partition between the nostrils, with a dental formula $\frac{3}{1}\frac{1}{1}\frac{3}{3}$, and including two distinct sets of forms, (a) the lower 'dog-like' apes (Cynomorpha), and (b) the higher 'man-like' forms (Anthropomorpha). See APE, ANTHROPOID APE, MONKEY.

Catawba, a name of wines, both still and sparkling, produced in various parts of the United States from the Catawba grape, the fruit of a variety of the *Vitis Labrusca*, a North American and Asiatic species, from which have been derived most of the cultivated North American varieties of the vine. It is often said that it was 'first found growing on the banks of the Catawba River' (in North and South Carolina); but it is on record that it was named by Major Adlum, who found it growing wild near Washington, D.C., about 1825. Catawba wines are of various grades, the best being of very decided value. The vine is extremely prolific, the fruit being large, of a deep coppery red, and very sweet. The Catawba grape does best on southern slopes, and on limestone soils. Its slight musky aroma pervades the wines made from it, and causes some connoisseurs to reject all but the very choicest of the vintage from the catalogue of first-class wines.

Cat-bird (*Turdus* or *Galeoscoptes carolinensis*), an American thrush, of the same group as the mocking-bird, which it resembles in its vocal powers. Its name refers to its mew-like cry when disturbed. It feeds on many kinds of fruit and berries, also on worms and insects; builds a large nest of dry twigs, weeds, &c., without any attempt at concealment, in a bush or tree, often in the immediate vicinity of human habitations, and shows extraordinary boldness in the defence of its young. It is a bird of passage, making its way northward in spring through Georgia and Carolina as far as Massachusetts. In winter it migrates southwards, and strayed specimens have been seen as great rarities on the continental coast of the North Sea.

Catch, a species of musical composition peculiar to England, written generally in three or four parts, and in the canon form. It was originally synonymous with the Round (q.v.), but the name has been appropriated to a species of it to which an absurd or humorous effect is given by the successive entries of the parts, interrupting or distorting the sense of the words into a new and unexpected meaning. They abounded in the Restoration period, when, as may be surmised, they often had a more than questionable coarseness. Hayes, Webbe, and Callcott, towards the end of last century, were fertile composers in this form. The 'Catch Club' was founded in 1761.

Catchfly, the name of the genus *Silene*, of which many species produce a sticky secretion on the calyx, the joints of the stem, &c., which prevents the access of ants and other creeping insects to the honey, so preserving it for the bees or other flying insects by which alone cross fertilisation is effected. Other Caryophyllaceæ, notably *Lychnis Viscaria*, possess the same means of defence. The Nottingham Catchfly is *Silene nutans*. The unrelated *Dionaea muscipula* is also sometimes called the Carolina Catchfly. See DIONEÆ.

Catchpoll, a sheriff's officer or bailiff, who had power to arrest. From *catch* and *poll*, 'the head'; not as is suggested by the spelling *catchpole* from *pole*: though in various places a long pole was in use for catching or holding criminals by the neck, having at the end of it an iron collar with a V-shaped opening, occasionally armed with spikes on the inside.

Cateau, LE, or CATEAU-CAMBRESIS, a town in the French department of Nord, on the Selle, 14 miles ESE. of Cambrai. Pop. (1886) 9686. Here in 1559 the treaty of Cateau-Cambresis was concluded between Henry II. of France and Philip II. of Spain.

Catechism, any compendious system of teaching drawn up in the form of question and answer. It is derived, through low Latin, from a Greek word *katecheō*, which means to resound, or sound into one's ears; to instruct by word of mouth. Persons undergoing instruction in the principles of Christianity were hence called *Catechumens* (q.v.).

Catechisms have long formed one of the principal means employed for popular instruction in the truths and duties of the Christian religion. The composition of the first catechisms was, in all probability, suggested by the ordinary oral instruction of catechumens, and was intended for the help both of teachers and pupils. It appears to have been in the 8th and 9th centuries that the first regular catechisms were compiled, of which that by Kero, a monk of St Gall, that of Notker Labeo of St Gall, and that ascribed to Otfried of Weissenburg in Alsace, are among the most noted. At later periods the use of catechisms prevailed chiefly among the opponents of the hierarchy, as among the Waldenses, the Albigenses, the Wyclifites, and, above all, among the Bohemian Brethren. The term catechism appears to have been first employed in its present sense among the latter. At an early period in the history of the Reformation the Reformers began to avail themselves of this method of popular instruction, and their catechisms became important instruments in that great religious movement. After Luther published in 1520 his primer of religion, entitled *A Short Form of the Ten Commandments, the Creed, and the Lord's Prayer*, several catechisms were prepared by leading Protestant theologians, that of Brenz (1527-28) being the most notable. In 1525 Justus Jonas and John Agricola had been intrusted with the preparation of a catechism, and Luther's visitation of the Saxon churches in 1528 led to his preparing his Larger and Smaller Catechisms (1529), which found a place among the standards of the Lutheran churches. The Larger he meant to be for teachers, the Smaller for the people. The latter has been constantly reprinted, and is very extensively used at the present day. A number of catechisms were published also by the theologians of the Reformed churches. The most noteworthy are the Geneva and Heidelberg catechisms, and those of Ecolampadius (Basel, 1526), Leo Jude (Zurich, 1534), and Bullinger (Zurich, 1555). The Geneva catechisms, Larger and Smaller, were the work of Calvin. The latter was published in French in 1536 (Lat. ed. 1538); the former

appeared in French in 1541 or 1542 (Lat. ed. 1545), was speedily translated into various languages, and became an acknowledged standard of the Reformed churches, not only in Switzerland but in the Low Countries, in France, and in Hungary. The First Book of Discipline of the Scottish Church (1560) directs that the children be taught this catechism—'which catechism is the most perfect that ever yet was used in the kirk'—every 'Sonday' afternoon in the presence of the people. The Church of Geneva has set aside the authority of Calvin's catechisms. The Heidelberg or Palatinate Catechism is of greater importance, however, than any other as a standard of the Swiss Reformed churches. It was compiled by the Heidelberg theologians, Caspar Olevianus and Zacharias Ursinus, at the request of the Elector Frederic III. of the Palatinate; it was published in 1563, was approved by several synods, and recognised as a symbolical book by the Synod of Dort in 1619, and has been translated into all the languages of Europe. It is the standard of the Dutch and German Reformed churches of America. A tercentenary edition of this catechism was published in German, Latin, and English at New York in 1863.—King James said at the Hampton Court Conference that in Scotland 'every one who was the son of a good man' thought himself competent to write a catechism. The catechisms of the Scottish Reformation must have been numerous. The most popular, until it was superseded by the Westminster Catechism, was John Craig's *Smaller Catechism* (Edin. 1591; edited by T. G. Law, 1883).—The doctrines of the Socinians are embodied in the greater and smaller Racovian Catechisms (Polish ed. Racow, 1605; Latin ed. 1609). Besides a catechism of 1660, in the form of a conversation between father and son, said to have been written by George Fox, the Quakers have that of Robert Barclay (1673), in which the answers are in the language of the Bible, the distinctive peculiarities of the sect being involved in the questions.

In the Church of Rome there were several catechisms published in Germany and elsewhere before the Tridentine settlement of doctrine. A Scottish catechism, known as Archbishop Hamilton's, was issued by authority of a provincial council in 1552, and was ordered to be read in church by the parish priests. But in 1563 the Council of Trent in its twenty-fourth session determined to compose and prescribe for the whole church an authorised form of catechism, which the bishops were to have translated into the vulgar tongue, and expounded to the people by the curates. The work was, however, not carried through by the council itself, and Pius IV. intrusted its completion to a commission of four theologians. Eminent scholars were also appointed to perfect its latinity, and when finished in 1564 it was once again submitted to a new commission under Cardinal Sirletus. It finally appeared in 1566 under the title *Catechismus Romanus ex decreto Concilii Tridentini Pii V. Pontificis jussa editus*. In form it is not catechetical, and it is addressed, not to the people, but to the curates as a guide to them in their instructions. It possesses very high authority, but is ill adapted for popular use. For lay teaching it has fallen into desuetude, and has been superseded by various catechisms of more private origin. The most popular of these were prepared by the Jesuit Peter Canisius. His larger work, entitled *Summa Doctrinae et Institutionis Christianae*, was published in 1554, and the shorter (1556) reached more than 400 editions, and was used in the schools of all countries. In the present day, as a general rule, each diocese possesses a catechism of its own approved by the bishop. In England the short 'Penny Catechism' is used by authority of all the bishops in concert.

The catechism called the *Orthodox Confession of the Catholic and Apostolic Eastern Church*, was prepared about 1640 by Peter Mogilas, metropolitan of Kief, and received symbolical authority from a synod at Jerusalem in 1672. It is often called the *Larger Russian Catechism*, to distinguish it from the *Smaller Catechism* prepared by order of Peter the Great in 1723. These were practically superseded by the catechisms of Platon, metropolitan of Moscow (first published in 1762), and of Philaret, also metropolitan of Moscow, which has since 1839 been in general use in the schools and churches of Russia.—Besides these catechisms, which have a historic interest, or are of importance from their symbolical character, there have appeared at all periods, since the Reformation, many others, both Protestant and Roman Catholic, some doctrinal, some controversial, some devoted to particular subjects, as the sacraments, or to particular purposes, as the preparation of candidates for admission to the Lord's Supper, some adapted to the mental capacity of very young children, &c. The opinion, however, has become prevalent, that doctrinal abstracts are not the best form in which religion can be presented to the young, and the use of catechisms has accordingly been in some measure relinquished in favour of other methods of instruction.

The catechism of the Church of England with which we are most familiar is the smaller one published in the Book of Common Prayer. It is in two parts: the first contains and explains the Baptismal Covenant, the Creed, the Ten Commandments, and the Lord's Prayer; the second explains the two sacraments, Baptism and the Lord's Supper. It is not known with absolute certainty who was the author of the first part; probably Cranmer and Ridley had the principal hand in framing the questions and answers. It was originally put forth in the reign of Edward VI., and condemned as heretical in the reign of Mary, and underwent several modifications from 1549 to 1661. It must not be confounded with Cranmer's Catechism (1548), which was a larger work, differently arranged, and probably translated chiefly from the Latin catechism of Justus Jonas. This first part of the church catechism was formerly spoken of as the *Shorter Catechism*. There was a *larger church catechism* compiled also in the reign of Edward VI. by Poyntet, Bishop of Winchester, and published, together with the 42 Articles, in 1553, and it corresponds in some degree with the smaller work above described. It was afterwards revised and enlarged by Dean Nowell, and published in 1570; and, though never officially promulgated by the church, it has some authority from having been approved by the lower house of Convocation. At the Hampton Court Conference (1604), the *Shorter Catechism* was considered too short, and Nowell's larger one 'too long for novices to learn by heart'; accordingly, at James I.'s suggestion, an addition was made to the former of that explanation of the two sacraments which now forms the second part of the church catechism. This is attributed to Dean Overall. The whole is a work much esteemed by all sections of the church as remarkable for its simplicity, truth, and catholicity. It, however, states sacramental doctrine in a way that is not very acceptable to the extreme Low Church party. Hence, the Prayer-book put forth by the Church of Ireland, while leaving the catechism otherwise untouched, ingeniously interpolates an additional question and answer (based on Article XXVIII.), which, in the opinion of many, tends to modify the ideas suggested by the catechism concerning Holy Communion. Modifications occur, too, in the Catechism of the American Episcopal Church. The rubrics in the Common Prayer-book enjoin

the teaching of the catechism in the church on Sundays and holidays after the second lesson at Evening Prayer; and the 59th canon contains a like injunction, imposing penalties on the clergy who neglect this. The custom of catechising in the church had fallen into almost universal disuse, but in many parishes it has been revived with excellent results.

The Larger and Shorter Catechisms, which, with the Westminster Confession of Faith, constitute the standards or symbolical books of the Presbyterian churches throughout the British empire and the United States of America, were compiled by the Assembly of Divines at Westminster (q.v.): the Shorter Catechism 'to be a directory for catechising such as are of weaker capacity'; the Larger, 'for catechising such as have made some proficiency in the knowledge of the Christian religion.' The Larger Catechism was presented to the English House of Commons on 22d October 1647; the Shorter on the 25th November 1647—and both, with proofs added, on or before the 14th April 1648; and in July 1648 both received the sanction of the General Assembly of the Church of Scotland—the General Assembly, in the act approving of the Larger Catechism, declaring it to be 'a rich treasure for increasing knowledge among the people of God,' and that 'they bless the Lord that so excellent a catechism has been prepared.' The Shorter Catechism has, however, been far more generally used for the purpose of instruction than the Larger, which has been generally felt to be too minute in its statements, and too burdensome to the memory to be employed as a catechism. Even the Shorter Catechism is regarded by many, who substantially adhere to its doctrine, as carrying the statement of dogmatic theology beyond what is proper for elementary instruction, whilst it has been long felt to be unsuitable for the very young and the very ignorant, and its use is now almost always preceded by that of catechisms more adapted to their capacity. Its influence, however, has been very great in forming the religious opinions, and in exercising and training the intellectual faculties, wherever Presbyterianism has prevailed; for it has been, and still is, in almost universal use among Presbyterians speaking the English language, and to a considerable extent among Independents or Congregationalists both in Britain and America. In Holland also, a translation of it has been much used. It is very generally regarded, by those whose doctrinal views are in accordance with it, as an admirable compend of Christian doctrine and duty. 'The older I grow,' said Carlyle—'and I now stand upon the brink of eternity—the more comes back to me the first sentence in the catechism which I learned when a child, and the fuller and deeper its meaning becomes: "What is the chief end of man?—To glorify God, and to enjoy Him for ever."—Catechisms without number had been issued by Puritan divines in England between 1600 and 1645. A large proportion of the members of the Westminster Assembly had previously published catechisms of their own. The authorship of the Assembly's Catechisms has been the subject of much debate, or at least the authorship of the first drafts of them; it being admitted that they were prepared with great care by committees of the Assembly. But the probability appears to be, that their authorship is to be ascribed entirely to these committees; and that, like the Westminster Confession of Faith, they are thus the result of the joint labours of many. See Ehrenfeuchter, *Geschichte des Katechismus* (1857); Niemeyer, *Collectio Confessionum* (1840); Schall's *History of the Creeds of Christendom* (3 vols. New York, 1876; Lond. 1877).

Catechu, a substance employed in tanning and dyeing and medicinally as an astringent. The catechu of commerce is obtained chiefly from two East Indian trees (*Acacia Catechu* and *A. Sina*). The former is common in most parts of India, and also in tropical East Africa, and the latter grows in Southern India, Bengal, and Gujerat. Catechu is known in India by the name *kaf* or *kut*. Cutch is another form of one or other of these names, and is a common commercial name. The trees are cut down when they are about a foot in diameter, and according to some accounts only the heart-wood is used, but other reports say that the whole of the woody part of the trunk is utilised. The catechu is obtained by cutting it into small chips, and boiling it in water, straining the liquid from time to time, and adding fresh supplies of chips, till the extract is of sufficient consistence to be poured into clay moulds; or when of the thickness of tar, it is allowed to harden for two days, so that it will not run, and is formed into balls about the size of oranges, which are placed on husks of rice or on leaves, and appear in commerce enveloped in them. Catechu is of a dark-brown colour, hard and brittle, and when broken has a shining surface. It possesses an astringent taste, but no odour. It is a very permanent colour, and is employed in the dyeing of blacks, browns, fawns, drabs, &c. Ordinary commercial catechu or cutch is composed of catechu-tannic acid, which is soluble in cold water, and catechin or catechuic acid, which is nearly insoluble in cold but soluble in boiling water. The latter can be separated in the state of minute, acicular, colourless crystals. It is often adulterated with earthy substances, but its ready solubility in water and alcohol should at once show the presence of such by leaving them behind in an insoluble state. Areca or Palm Catechu, sometimes called Ceylon Catechu, differs wholly from the above. It is got from the ripe nuts of the Betel palm, which yield, by boiling, a black, very astringent extract, resembling true catechu, but of inferior quality. This substance is rarely exported from India (see ARECA, BETEL).—Gambir (q.v.) may be regarded as a kind of catechu. *Terra Japonica*, or *Japan Earth*, is an old name for catechu, not quite disused, given in mistake as to its nature and origin. About 6000 tons of catechu or cutch are annually imported into Great Britain from India.

Catechumens (Gr. *katechoumenoi*, persons undergoing a course of instruction; see CATECHISM), the appellation given, in the early Christian church, to those converted Jews and heathens who had not yet received baptism, but were undergoing a course of training and instruction preparatory to it. They had a place assigned them in the congregation, but were not permitted to be present at the dispensation of the Lord's Supper, which from the end of the 2d century was regarded as a sacred mystery. The name Catechumens first occurs as the designation of a separate body in the time of Tertullian, and their distribution into different classes or grades according to their proficiency, is first referred to by Origen. The most famous catechetical school of the early church was that of Alexandria, which had Pantænus, Clement, Origen, Dionysius and others among its teachers. The only extant specimens of the ancient catechetical teaching (which was not necessarily by question and answer) are twenty-three lectures by Cyril of Jerusalem (348), and Augustine's *De catechizandis Rudibus*.—The term Catechumens was afterwards employed to designate young members of the Christian church who were receiving instruction to prepare them for confirmation or for the Lord's Supper, and it is still often used in this sense. See DISCIPLINA ARCANI.

Categories, in philosophy, the highest classes under which objects of knowledge can be systematically arranged, understood as an attempt at a comprehensive classification of all that exists. The name has come down to us from Aristotle, in whose system the categories are ten in number: *Substance, quantity, quality, relation, place, time, situation, possession, action, and suffering*. From the point of view of logic, these may be reduced to two: substance and attribute; of metaphysics, to being and accident. The Cartesians had the three categories—substance, attribute, and mode; Leibnitz—substance, quantity, quality, action or passion, and relation; and Locke—substance, mode, and relation. J. S. Mill classifies all existences or describable things as follows: (1) Feelings, or states of consciousness, the most comprehensive experience that the human mind can attain to, since even the external world is only known as conceived by our minds; (2) the minds which experience those feelings; (3) the bodies, or external objects, which are supposed to excite all that class of feelings that we denominate sensations; (4) the successions and co-existences, the likenesses and unlikenesses, between feelings or states of consciousness. Although those relations are considered by us to subsist between the bodies, or things, external to our minds, we are driven in the last resort to consider them as really subsisting between the states of each one's own individual mind.

The categories of Kant are conceived under a totally different point of view. The root-notions of the understanding (*Stammbegriffe des Verstandes*), they are the specific forms of the *a priori* or formal element in rational cognition—forms inherent in the understanding, under which the mind embraces the objects of actual experience. The Kantian philosophy supposes that human knowledge is partly made up of the sensations of outward things—colour, sound, touch—and partly of mental elements or functions existing prior to all experience of the actual world. (This is the point of difference between the school of Locke, who rejected all innate ideas, conceptions, or forms, and the school of Kant. No such question was raised under the Aristotelian categories.) Kant's categories are as follows: (1) Quantity, including unity, multitude, totality; (2) Quality, including reality, negation, limitation; (3) Relation, including substance and accident, cause and effect, action and reaction; (4) Modality, which includes possibility, existence, necessity. These indicate the elements of our knowledge *a priori*; and though they are the necessary conditions under which alone experiences can be realised to the mind, are merely subjective forms of its own activity, distinct from and inapplicable to the world of *noumena*—the thing in itself—that lies outside and beyond. Fichte based the whole system of the categories of reality on the affirmation of itself by the Ego—the primitive function of self-consciousness. Hegel carried this further, and showed that this primitive function supplied the principle needed to harmonise and unify the objective and subjective elements in thought. Thought and being are ultimately identical, and the categories are thus merely definite aspects or determinations (*Bestimmungen*) of the universal of thought, which is identical with reality or actual existence.

Catenary. The catenary is the curve formed by a flexible homogeneous cord hanging freely between two points of support, and acted on by no other force than gravity, the name being suggested by Lat. *catena*, 'a chain.' The catenary possesses several remarkable properties, one of which is, that its centre of Gravity (q.v.) is lower than that of any curve of equal perimeter, and with the same fixed points for its extremities. It is of importance for the theory of suspension Bridges (q.v.).

Catenipora, a genus of fossil tabulate corals peculiar to Palaeozoic strata, confined in Britain to the Silurian measures. See CORAL.

Cateran (Gaelic and Irish, *ceatharnach*, 'a soldier'), originally an Irish or Highland soldier, a kern; usually, however, a Highland reiver or free-booter. See CLAN, HIGHLANDS.

Caterpillar, the larval stage of butterflies and moths (Lepidoptera), and the representative in this special order of the grub, maggot, or larva phase in the life-history of many insects.

General Structure.—The caterpillar, so familiar in its external appearance, has usually 12 body-rings, not including the head, is provided with strong biting jaws, strikingly contrasted with the mouth organs of the adult, has three pairs of five-jointed clawed legs on the region corresponding to the thorax, and usually five rudimentary stumps or pro-legs on the abdomen. These unjointed appendages are borne on the sixth to the ninth, and on the twelfth segments of the body; some of them may be absent; in the majority of cases they are adapted for clambering. The body may be naked or covered with hairs, bristles, and spines, which, in caterpillars

Fig. 1.

a, *Chocrocampa tersa*, showing eye-like spots; *b*, young caterpillar of *Delilephila Euphorbide* (after Weismann). Cf. fig. 5.

living an exposed life, are usually brightly coloured. The large head is divided by a median line, and bears six eye-spots on each side, a pair of short three-jointed feelers, strong upper jaws or mandibles, besides jointed palps on the two successive pairs of mouth appendages. Two well-developed spinning organs open on the second pair of maxillae forming the lower lip or *labium*. On each side, on the first ring, and on the fourth to the eleventh, there are nine pairs of *stigmata* or openings into the respiratory air-tubes. Hatchesek has observed the appearance of three pairs of stigmata on the jaw-segments of the head. The colours are familiarly bright in many instances, and may have their seat in the cuticle or in the skin below, or very frequently in deeper regions of the body. A metallic sheen is sometimes superadded. The surface is often beautifully marked longitudinally, or transversely, or with ring-spots and eye-spots. Odoriferous and other glands frequently occur on the skin, and are in some cases (*Dicranura*, *Orgyia*) eversible. The internal anatomy of the caterpillar, though essentially resembling that of the adult, differs in some striking features. Thus while the larva has 11 to 12 separate nerve ganglia in the ventral chain, the adult insect has usually only two separate ganglia in the thorax, and five in the abdomen. The digestive system is comparatively short and simple; the circulatory and respiratory systems much like those of the adult; a few aquatic caterpillars have gill-like appendages.

History.—The caterpillar develops like any other larva from the segmented egg and differentiating embryo; its life is usually more or less active and voracious; it undergoes several moults

ings or *ecdyses*; begins to develop some of the adult structures, and falls into a quiescent pupa, chrysalis, or aurelia stage. The pupa is usually (except in butterflies) insheathed in a silken cocoon, may be fixed or free, suspended by one thread or more to leaf or branch, or hidden away underground. Among butterflies, the uninsheathed pupa may be fastened head downwards by a single silken rope fastened to the tail end (*pupa suspensor*), or head upwards with an extra suspensor round the body (*suscinete*). The intimate structural changes associated with the remarkable alteration in habit of life have not yet been fully followed. One of the most important features is the appearance on the caterpillar of what are known as 'imaginal discs,' which appear to arise from the skin, and give origin to the limbs and wings of the adult insect. In the quiescent pupa stage very important changes go on, amounting to more or less of a remaking of the entire body; but it is not possible within the present limits to describe the changes undergone by the digestive, nervous, and other systems, or the very marked transformation of the mouth appendages. The cocoon in which the pupa becomes the perfect insect may be altogether absent, or very slight, or strikingly compact and protective. Some firm cocoons open very neatly from the inside by valvular lips, and in other cases the moth is known to soften the walls of its prison by means of some secretion. The gilded colour of some pupae (chrysalids indeed), so mineral-like in appearance, not improbably arose, it has been suggested, in hot dry countries, and had a protective value among dry rocks. It has been shown experimentally to arise as a direct consequence of bright surroundings. The cocoon occasionally consists solely, or almost solely, of the hairs of the larva; in some cases leaves, wood, earth, &c. are used in construction; in most moths it is spun. The work of spinning the usual cocoon is carried on almost ceaselessly, sometimes for four or five days, and Trouvelot calculates that the larva of *Polyphemus* in distributing its silk must have moved its head to and fro about 254,000 times.

A very primitive insect type is represented by a widely distributed genus *Peripatus* (q.v.), which remains permanently at a sort of caterpillar level, and serves to connect jointed-footed animals or arthropods with worm-like forms. The caterpillar may be interpreted as in part a recapitulation of this historical stage in the evolution of insects.

Fig. 2.—*Peripatus*:
Survival of ancestral insects (from Moseley).

The caterpillar thus represents the prolongation of an ancestral and embryonic stage, while many of its characters have arisen as secondary adaptations to its peculiar mode of life. Between each moult there is a period of quiescence, and this becomes greatly prolonged in that all-important moult in which the mouth organs of the larva are modified into those of the adult. Free life at a period so momentous would evidently be disadvantageous even if it were possible. The pupa, furthermore, may come to have a secondary importance other than that of simply being an exhausted quiescence at the final moulting; it may come to be of vital moment as a protective phase, by means of which the insect survives the cold of winter or the drought of the dry season. In one case (*Cossus*) the preparatory stages may be prolonged for three years. From

another point of view the life-history may become more intelligible—viz. from the side of its physiology. In the embryonic development the young form is built up at the expense of its endowment of food-capital. The first chapter is one of passivity and living on past gains. When these are exhausted, and the embryonic processes completed, the larva emerges, hungry, voracious, active. In its ravages and moultings it exhibits alternate minor rhythms of activity and passivity. Finally having laid up a store of food-capital in the recesses of its 'fatty body,' it falls asleep into the more emphasised quiescence of the pupa stage. During this phase of fasting and passivity, and of life sustained by past gains, momentous changes, associated with gradual loss of weight, take place, and the final debut is made by the appearance of the active, frugal, sexually-mature, comparatively short-lived adult. It is not yet possible to rationalise the details of the life-history, but in the alternations of activity and passivity common to all living organisms, and here more marked than in any other case, the solution must be sought.

Protection and Colour.—Caterpillars are evidently enough tempting juicy morsels to birds and other insect-eating animals; their slow movements render them liable to ready capture, and, as Wallace has pointed out, their soft-walled tense structure is 'extremely dangerous, for a slight wound entails great loss of blood, while a moderate injury must prove fatal.' It is therefore not surprising to find that caterpillars, in common with the larva of other insects, have found out, or have become the subjects of, various devices for evading their enemies. The more conspicuous forms almost always possess some unpleasant attribute in taste or smell, either in the tissues generally or in special glands. Weismann notes how a curious lashing about of the tail may preserve one form, and how the juices of another attract a protective body-guard of ants. Others are so uncanny in the disposition of their hair-tufts and colour, or in the 'terrifying attitudes' which they assume, that their cautious though hungry foes leave them alone. But distaste and repulsion may on stress of hunger be overcome, and only a relatively small number of larvae trust to this mode of defence. Thus others are in their colour and

Fig. 3.—Terrifying attitude of larva of *Diceranura cinula* (after Poulton).

markings so like the plants on which they feed, or the ground on which they crawl, that they avoid detection, and this protective resemblance is often not merely general and superficial, but detailed and exact. Thus some when fixed as pupa to the stems of plants, are almost indistinguishable from knobs or stunted twigs. In the twig-like attitude the supporting thread is sometimes dispensed with. Others are like little splinters of wood, or the curled margins of withered leaves. The hairs and fleshy tubercles may prevent the casting of a sharp shadow. Nor is the 'mimicry' confined to resembling the parts of plants, but a palatable insect may probably save itself by approximating in colour to one that is distasteful. Mr Bates observed a large caterpillar deceptively like a small venomous snake. Protective resemblance may be further abetted by unpalatable taste or unpleasant smell. Some forms hide during the

day; others feign death when caught. In more than one species (*Dicranura*) the larva spurts out formic acid.

Darwin had been impressed with the colours of caterpillars, which, occurring as they do on larvæ, could not be referred to the action of sexual selection. Though, as an exception, a male caterpillar may be much brighter than the female, the two sexes are all but invariably the same, and no sexuality or sexual choice is yet developed. Wallace attacked the problem, and maintained that the conspicuous forms were distasteful to birds and reptiles, and that the conspicuous colours were advantageous reminders of unpalatableness. To this Poulton has added the necessary caution, that animals forced by hunger will eat the distasteful beauties, and come to like them.

Fig. 4. Hawthorn twig with attached twig-like larva (a) of *Rumia Cradegata* (after Poulton).

For a most interesting series of studies on the colour and markings of caterpillars, the reader should consult Professor Weismann's *Studies in the Theory of Descent*, and the valuable editorial notes of the translator, Professor Meldola. The whole burden of Weismann's work is to show that in the marking and colouring (of the Sphingide in particular) no action of an impelling vital force can be recognised, but that 'the origination and perfection of these characters depend entirely on the known factors of natural selection and correlation,' though of course natural selection can only operate on the variations possible to the physical constitution and conditions of the organism. In tracing the presumed historical evolution of the Sphingide, which is more or less fully recapitulated in the individual development, he starts (1) from concealed or subterranean, white or yellow, forms, with a horn on the tail and with bristles, but without markings; (2) in adaptation to life on linear plants like grasses, longitudinal markings are evolved and confirmed by natural selection;

Fig. 5.

a, Caterpillar of *Sphinx Convolvuli*; b, larva of *Macroglossa Stellatarum*, showing lines and spots (after Weismann).

(3) these are succeeded by oblique stripes, spreading from one segment to another, evolved by natural selection and correlation, and followed by the disappearance of the longitudinal lines which spoil the effect; (4) on the second last segment ring-spots then appear, and tend to spread to other rings; these are deceptively like the berries of the food-plant at one time, or have a terrifying eye-

like appearance afterwards, and are often signals of distastefulness.

Poulton made a long series of experiments of a most interesting nature on the subtle relations between Lepidopterous larvæ and their surroundings. The colours and markings have a double source: (1) pigments derived from the food-plants; (2) pigments proper to the larvæ. A larva may be coloured from either or both of these sources; all greens seem due to the chlorophyll, and most yellows to the xanthophyll of plants; other colours to the proper pigments of the larvæ. The derived pigments are more frequently the basis of general resemblances to surroundings, the true pigments of special and detailed likeness. Poulton arranges the causes of colour in larvæ, in the presumed historic order of their employment, thus: (1) Ready-made colour in the internal tissues and organs, in the digestive tract, fat, and dorsal blood-vessel; (2) derived pigments which have passed through the walls of the digestive tract into the blood or the tissue under the cuticle; (3) true pigment in the cuticle and in the layer immediately below (the *hypodermis*). But the point of most general interest is the relation between the colour of the larvæ and that of their food-plants. Within the same species the colours may vary to suit the colour of the feeding-ground. Abundant instances of this are recorded in Meldola's notes to Weismann's *Studies*. McLachlan noted for instance that the larvæ of *Eupithecia absynthiata* were yellowish on the yellow ragweed (*Senecio jacobae*), reddish on the purplish centaury (*Centaurea nigra*), and white on the mayweed (*Matricaria*). Poulton has the credit of analysing this interesting relation. He has shown that the influence of the food-plant must act throughout a long period of larval life, that the effects probably accumulate during successive generations, and that the result cannot be referred to the direct influence of the material eaten. The interpretation is rendered particularly difficult 'by the gradual working of the process, often incomplete in a single life, by the excessively complex and diverse result, and by the special character of the stimulus, for it is only part of the environment which produces any effect.' In the case of the larva of *Smerinthus ocellatus*, Poulton has shown that the colour relation is adjustable within the limits of a single life, and that the predominant colour of the plant is the inciting stimulus. The colour adaptation is not in this case at any rate due to the gradual working of natural selection, but to relatively immediate power enabling the larva to suit itself to its conditions. But the influence, though in one sense direct, is a very subtle one. Poulton's investigations show (1) that larvæ have certain hereditarily transmitted tendencies towards certain colours; (2) that the colour of the leaf, and not the substance eaten, is the agent which influences the larval colours; (3) that the influence is an intricate nervous one, 'making itself felt by affecting the absorption and production of pigments rather than their modification when formed;' and (4) that individual variations are comparatively unimportant, though it is quite possible that variation began somewhat uselessly in the pigments in the blood, &c., and were afterwards 'rendered efficacious by co-ordination with the environment.' Some of Mr Poulton's most beautiful recent experiments (1887) are those which show how the golden surroundings of a gilt-lined box favour the production of golden pupæ. The above naturalist, to whose observations this article is so much indebted, has done more than any one else to penetrate into the physiological conditions of caterpillar colour, but much still remains to be

done in elucidating the rôle of colour in the constitution of these and other animals.

General Life.—As already noted, most caterpillars lead an active life, some roving only at night, others also in the daytime. Young larvae have been observed to seek the light. Their movements are guided by an appreciation of the force of gravitation; they usually crawl upwards; and they always know their food-plant when they come to it. Their frequent falls from, for them, considerable heights, are broken, it has been suggested, by the springy hairs with which they are so often covered. Many of them seem to have an insatiable hunger, and eat straight on. Their ravages among vegetables and other plants are only too well known. Some forms are carnivorous, and Mr Poulton has suggested that this might arise from cannibalism induced by scarcity of food, as his observations vividly indicate. While older larvae will apparently rather starve than take to a new food-plant, it has been conclusively shown that the newly hatched larva is not so fastidious, but 'is free to form special relations with occasional or rare food-plants.' Trounvelot's experiments on the larvae of *Polyphemus* showed that a caterpillar, fifty-six days old, had consumed not less than one hundred and twenty oak leaves, weighing in all three-fourths of a pound, and had drunk not less than half an ounce of water. The food would weigh 86,000 times the original weight of the larva. 'Of this, about one-fourth of a pound becomes excrementitious matter; 207 grains are assimilated, and over five ounces evaporated.' A few larvae (*Nymphula*, &c.) are aquatic, many bore in wood, leaves, and soft vegetable substances, others are largely subterranean.

The caterpillars of some of the silkworm sub-order (*Bombycina*) live together within a common pouch-like cradle, and others move in file-like processions (see **ARMY WORM**). Migrating caterpillars (*Noctua*) have been described, which move in search of food in vast armies, marching straight on over everything, until a fit pasturage is found. In one case (quoted by Kirby and Spence from the *Charleston Courier*, May 1842) the passage of such a host is said to have made the ground black for days; in another instance reported from America, they stopped a heavy train going at the rate of 10 or 12 miles an hour.

Comparatively few caterpillars reach maturity (happily for the sake of the plants in the next season); many are destroyed by the weather, many by hungry birds, reptiles, and other animals, and many by insect pests of the families Ichneumonidae (see **ICHNEUMON-FLY**) and Tachinaria. The ichneumon-flies pierce the caterpillars, and make them the receptacles of their eggs and the edible cradles of their larvae.

As typical injurious caterpillars may be noticed, (1) on vegetables, those of the cabbage-moths (e.g. *Mamestra brassicae*, and several species of *Pieris* or *Pontia*), the turnip-moths (*Noctua segetum*, *Cerostoma xylostella*), the silver Y-moth (*Plusia gamma*), the carrot-moths (*Depressaria*), the hop-moths (*Dasychira*, *Hepialus*, *Pyralis*), the pea-moth (*Grapholitha pisana*), the death's-head (*Sphinxatropus*); (2) on trees, those of the goat-moth (*Cossus ligniperda*), the wood leopard-moth (*Zeuzera aesculi*), the buff-tip moth (*Pygmae bucephala*), the lackey-moth (*Bombyx elisio-campa neustria*), &c. See Miss Ormerod's *Injurious Insects*.

The devastations of caterpillars are to some extent compensated for by the fertilising work of the adults, and by the silk of the silkworms. But apart from their destructiveness and utility, they are full of interest and of scientific puzzles. Old Swammerdam saw in their metamorphosis

'the resurrection painted before our eyes,' while moralists and poets have often delighted in pointing out the analogies suggested by the crawling immature caterpillar, with faint promise of its future, by the seeming death and coffin-like cocoon of the chrysalids, by the new birth, glory, and heavenward flight of the perfected forms.

LITERATURE.—Balfour, *Embryology*, vol. i.; Kirby and Spence, *Introduction to Entomology*; Lubbock, *Metamorphoses of Insects* ('Nature' series); Packard, *Guide to the Study of Insects*; Poulton, *Transactions of Entomological Society* (1885-6-7), *British Association Report* (1887), *Proceedings of Zoological Society* (1887); Wallace, *Proceedings of Entomological Society* (1867); Weismann (translated by Meldola), *Studies in the Theory of Descent* (1880-82); Wilson, *Larvae of British Lepidoptera and their Food Plants* (London, 1880).

Catesby, MARK, naturalist, born about 1679, probably in London, travelled in North America in 1710-19 and 1722-26, and published *Natural History of Carolina, Florida, and the Bahama Islands* (2 vols. 1731-43), *Hortus Britanno-Americanus*, and a work on the fishes, reptiles, and insects of the Isle of Providence. German translations of the first and last appeared at Nuremberg. He died in London, 23d December 1749.

Catesby, ROBERT, born in 1573, was a Northamptonshire Catholic of good fortune and lineage, being sixth in descent from Richard III.'s Catesby, who was hanged three days after Bosworth. Robert, however, had suffered much as a recusant both by fines and imprisonment, when in 1604 he engaged in the Gunpowder Plot (q.v.). He was shot dead in the defence of Holbeache House, 8th November 1605.

Cat-fish, in Britain, is usually a name for the Wolf-fish (q.v.).—In America the name is commonly applied to a very different fish, one of the genus *Pimelodus* and family Siluridae. Sixteen species occur in the lakes and rivers of North America. The skin is naked, and the head has eight fleshy barbules. The Common Cat-fish (*P. atrarius*), or Horned Pout, is one of the commonest river fishes of the United States, especially in the east and north. It is from 7 to 9 inches in length, and is a very important food fish, though its flesh, like that of all the cat-fishes, is insipid. Like all its congeners it prefers muddy bottoms, and is sluggish in its movements. The Great Lake Cat-fish (*P. nigricans*) is from 2 to 4 feet long, weighs from 6 to 30 pounds, and is found in lakes Erie and Ontario.

Catgut is employed in the fabrication of the strings of violins, harps, guitars, and other musical instruments; as also in the cords used by clock-makers, in the bows of archers, and in whips. It is generally prepared from the intestines of the sheep, rarely from those of the horse, ass, or mule, and *not* those of the cat. The first stage in the operation is the thorough cleansing of the intestines from adherent feculent and fatty matters; after which they are steeped in water for several days, so as to loosen the external membrane, which can then be removed by scraping with a blunt knife. The material which is thus scraped off is employed for the cords of battledoors and rackets, and also as thread in sewing the ends of intestines together. The scraped intestines are then steeped in water, and scraped again, when the large intestines are cut off and placed in tubs with salt, to preserve them for the sausage-maker; and the smaller intestines are steeped in water, thereafter treated with a dilute solution of alkali (4 oz. potash, 4 oz. carbonate of potash, and 3 to 4 gallons of water, with occasionally a little alum), and are lastly drawn through a perforated brass thimble, and assorted into their respective sizes. In order to destroy any adherent matter which would lead

to putrefaction, and the consequent development of offensive odours, it is customary to subject the catgut to the fumes of burning sulphur—i.e. sulphurous acid, which acts as an Antiseptic (q.v.), and arrests decomposition. The best strings come from Italy, and are used for musical instruments. These are known as *Roman strings*, but they are made in several Italian towns, the most valuable coming from Naples. About 10 per cent. of the violin strings manufactured are *false*—i.e. they produce two sounds. Gut strings for musical instruments become useless after being kept a few years. Cord for clockmakers is made from the smallest of the intestines, and occasionally from larger ones, which have been split longitudinally into several lengths. The catgut obtained from the intestines of horses, asses, and mules is principally made in France, and is employed in the same way as leather belts for driving lathes and other small machines.

• **Catha**, a genus of Celastraceæ, often reckoned under Celastrus. *C. edulis*, Arabian Tea, the Khât of the Arabs, is a shrub highly valued by them on account of its leaves, which are chewed or infused like coffee or tea, to which its properties seem essentially similar. It is cultivated along with coffee.

Cathari (Gr. 'pure'), or CATHARISTS, a name assumed by a widely diffused Gnostic sect of the middle ages, which took its rise most probably among the Slavs in Southern Macedonia, and spread over the whole of Southern and Western Europe. In Thrace it found a kindred sect in the Paulicians (q.v.), who had been transported thither about 970, and they were there known as Bogomili (q.v.). In the second half of the 12th century they were in great strength in Bulgaria, Albania, and Slavonia, and divided into two branches, distinguished as the Albanensians (the more extreme section), and the Concorezensians (named from Goriza in Albania). It is remarkable that the name *Bulgari*, by which they were known to the returning French crusaders, is the origin of the low French word *Bougre*, just as the German word for 'heretic' (*Ketzer*) is derived from *Gazzari*, the Lombard form of *Cathari*. In Italy the heresy first appeared at Turin about 1035, and existed down to the 14th century. Its adherents were called *Patarini*, from *Pataria*, a street in Milan frequented by rag-gatherers, where they held their secret meetings in 1058. The Cathari reached their greatest numbers in Southern France, where they were commonly called Albigenses (q.v.) or *Publicans*, the latter term being a corruption of *Paulicians*, with whom they were confounded. After the great Albigensian wars, they were gradually rooted out by the Inquisition, and after the first half of the 14th century they disappear from history. The Cathari based their teaching on the New Testament and an apocryphal 'Vision of Isaiah' and 'Gospel of John.' The only extant Catharist writing is a short ritual in the Romance language of the 13th-century troubadours (printed at Jena in 1852 by Professor Cunitz from the MS. at Lyons). All the Cathari held more or less Manichean views, and practised a rigid asceticism. Deliverance from evil was only to be attained by renunciation of the (material) world, including marriage, property, and the use of animal food. They distinguished between the great mass of their *Credentes* or 'Believers,' and the *Perfecti*, who had received the Baptism of the Spirit by the laying on of hands, called *Consolamentum*, because in it the Comforter was imparted. These 'pure' ones, estimated at only 4000 in all Europe about the year 1240, formed the Catharist Church—the 'only true and pure church on earth.' Their worship was

extremely simple, and their church government was by bishops (each with two assistants, the *Filius Major* and the *Filius Minor*) and deacons. See C. Schmidt, *Histoire et Doctrine de la Secte des Cathares* (2 vols. Paris, 1849); Lombard, *Pauliciens, Bulgares et Bons-hommes* (1879).

Catharine, the name of several Christian saints: (1) *St Catharine* proper, a virgin of royal descent in Alexandria, who publicly confessed the gospel at a sacrificial feast appointed by the Emperor Maximinus, and was therefore put to death, after they had vainly attempted to torture her on toothed wheels, 307 A.D. Hence the name of 'Catharine wheel.' No less than fifty heathen philosophers sent by the emperor to convert her in prison were themselves converted by her winning eloquence; whence she is the patroness of philosophers and learned schools. Having steadily rejected all offers of earthly marriage, she was taken in vision to heaven, when the Virgin presented her to her son, and Christ plighted his troth to her with a ring. This subject has been a favourite one with many artists (as signifying the union of the redeemed soul with Christ); the Christ being usually represented as an infant. It has been suggested that the attributes of the unhistorical St Catharine seem to have been derived from those of the actual Hypatia (q.v.), a heathen who suffered death at the hands of Christian fanatics. St Catharine's festival falls on 25th November. (2) *St Catharine of Sienna*, one of the most famous saints of Italy, was the daughter of a dyer in Sienna, and was born there in 1347. While yet a child she practised extraordinary mortifications, and devoted herself to perpetual virginity. She became a Dominican, and therefore afterwards a patron saint of the Dominicans. Her enthusiasm converted the most hardened sinners, and she was able to prevail upon Pope Gregory XI. for the sake of the church to return from Avignon to Rome. She was favoured, it was said, with extraordinary tokens of favour by Christ, whose Stigmata (q.v.) were imprinted upon her body. She wrote devotional pieces, letters, and poems, a recent edition of which is Tomassco's (4 vols. Florence, 1860). Her festival falls on 30th April. See Drane's *History of St Catharine of Sienna* (2d ed. 2 vols. 1887).—*St Catharine of Bologna* (1413-63; festival 9th March) and *St Catharine of Sweden* (died 1381, festival 22d March) are of less note.

Catharine de' Medici, the wife of one king of France, and the mother of three, was the daughter of Lorenzo de' Medici, Duke of Urbino, and was born at Florence in 1519. In her fourteenth year she was brought to France, and married to Henry, the second son of Francis I. The marriage was a part of the political schemes of her uncle, Pope Clement VII., but as he died soon after, she found herself friendless and neglected at the French court. In these circumstances she conducted herself with a submission which seemed even to indicate a want of proper spirit, but which gained her the favour of the old king, and in some measure also of her husband. The accession of the latter to the throne of France, however, made very little difference in her situation. It was not till the accession of her eldest son, Francis II., in 1559, that she found some scope for her ambition. The Guises at this time possessed a power which seemed dangerous to that of the throne, and Catharine entered into a secret alliance with the Huguenots to oppose them. On the death of Francis II. in 1560, and accession of her second son, Charles IX., the government fell entirely into her hands. Caring little for religion in itself, although she was very prone to

superstition, she disliked the Protestants, chiefly because their principles were opposed to the absolute despotism which she desired to maintain. Yet she sought to rally the Protestant leaders around the throne in order to serve as a counterpoise to the Guises. This attempt having failed, and the civil war which ensued having ended in the peace of Amboise, highly favourable to the Protestants, she became alarmed at the increase of their power, and entered into a secret treaty with Spain for the extirpation of heretics; and subsequently into a plot with the Guises, which resulted in the fearful massacre of St Bartholomew's Day. This event brought the whole power of the state into the hands of the queen-mother, who boasted of the deed to Roman Catholic governments, and excused it to Protestant ones, for she now managed all the correspondence of the court. About this time she succeeded, by gold and intrigues, in getting her third son, afterwards Henry III., elected to the Polish throne. But her arbitrary and tyrannical administration roused the opposition of a Roman Catholic party, at the head of which was her own fourth son, the Duke of Alençon. It was very generally believed that she was privy to the machinations that led to his death. When, after the death of Charles IX., Henry III. returned from Poland to be king of France, his mother still ruled the court, and had the principal share in all the intrigues, treacheries, and political transactions of that wretched time. Having betrayed all who trusted them, she and her son found themselves at last forsaken and abhorred by all. The League and the Guises had no more confidence in them than had the Protestants and Henry of Navarre. Vexation on this account preyed on the proud heart of the queen-mother in her last days; and amidst the confusion and strife of parties, she died at Blois on 5th January 1589, unheeded and unlamented. Catharine de' Medici may fairly be regarded as a representative woman of an age when the first principles of human conduct were hopelessly confounded by religious strife and the intrigues and corruptions of courts. Virtue had given place to luxury, extravagance, cunning sensuality, and cruelty. She was only a prominent example of qualities which the prevailing conditions of the time tended to develop. See Reumont's *Jugend Caterinas de' Medici* (Berlin, 1854), T. A. Trollope's *Girlhood of Catharine de' Medici* (1856), Capeligue's *Catherine de Medici* (Paris, 1856), and La Ferrière's *Lettres de Catherine de Medici* (2 vols. Paris, 1880-85).

Catharine I., wife of Peter the Great, and Empress of Russia. She was a peasant's daughter, and her original name was Martha Skavrouska. The date of her birth is about 1680. Being left an orphan, she was brought up chiefly by a Lutheran pastor, Glück, in Marienburg, Livonia. In 1702 she married a Swedish dragoon, but Marienburg being taken by the Russians in the same year, she was made prisoner, and became the mistress of Prince Menshikoff. She then attracted the notice of Peter the Great. In 1703 she went over to the Greek Church, and took the name of Catharina Alexievna. After being for some years the emperor's mistress, she was privately married to him in 1707; and the marriage was publicly avowed in 1711. When Peter the Great and his army seemed entirely in the power of the Turkish army on the Pruth in 1711, Catharine, according to the common account, managed by skilful bribery to procure the deliverance of the Russians. Catharine was now received into greater favour than ever, and was solemnly crowned in 1712. The story, however, does not rest on sufficient evidence. At any rate Catharine continued to enjoy her high position till the death of Peter in 1725. The new party con-

cerned in promoting the reforms of Peter the Great supported Catharine's claim to be his successor, and she was acknowledged Empress and sole Ruler of All the Russias. Under Menshikoff's direction, the affairs of government went on well enough for a time; but the empress ere long began to yield to the influence of a number of favourites, addicted herself to drunkenness, and lived such a life as could not fail to hurry her to the grave. She died 17th May 1727. See PETER.

Catharine II., Empress of Russia, was born at Stettin in 1729. Her father, the Prince of Anhalt-Zerbst, was a Prussian field-marshal and governor of Stettin. She received the name of Sophia Augusta; but the Empress Elizabeth of Russia having selected her for the wife of her nephew and intended successor, Peter, she passed from the Lutheran to the Greek Church, and took (like the Empress Catharine I.) the name of Catharina Alexievna. In 1745 her marriage took place. She soon quarrelled with her husband, and both of them lived a life of unrestrained vice. Among his attendants was a Count Soltikoff, with whom her intimacy soon became scandalous; and Soltikoff was sent on an embassy abroad. But the young Polish count, Stanislaus Poniatowski, almost immediately supplied his place. After the death of the Empress Elizabeth in 1761, Peter III. ascended the Russian throne; but the conjugal differences became continually wider. Catharine was banished to a separate abode; and the emperor seemed to entertain the design of divorcing her, declaring her only son, Paul, illegitimate, and marrying his mistress, Elizabeth Woronzoff. The popular dislike to Peter, however, rapidly increased; and at length, he being dethroned by a conspiracy, Catharine was made empress. A few days afterwards Peter was murdered (July 1762). What participation his wife had in his murder has never been well ascertained.

Catharine now exerted herself to please the people, and among other things, made a great show of regard for the outward forms of the Greek Church, although her principles were, in reality, those prevalent among the French philosophers of the 18th century. The government of the country was carried on with great energy; and her reign was remarkable for the rapid increase of the dominions and power of Russia. Not long after her accession to the throne her influence secured the election of her former favourite, Stanislaus Poniatowski, to the throne of Poland. In her own empire, however, discontentment was seriously manifested, the hopes of the disaffected being centred in the young prince Ivan, who was forthwith murdered in the castle of Schlüsselburg. From that time the internal politics of Russia consisted chiefly of court intrigues for the humiliation of one favourite and the exaltation of another. The revolt of the Cossack Pugatcheff in 1773, though for a time it looked serious, only served to fortify her throne. The first partition of Poland in 1772, and the Turkish war which terminated in the peace of Kainardji in 1774, vastly increased the empire. In 1787 she made a progress in her southern provinces through flourishing towns, villages, and festive scenes; but the whole was a sham, having been got up for the occasion by Potemkin to impress Catharine with the prosperity of her empire. The Turkish war which terminated in the peace of Jassy in 1792 had similar results, and also the war with Sweden, which terminated in 1790. The second and third partitions of Poland, and the incorporation of Courland with Russia, completed the triumphs of Catharine's reign. She also began a war with Persia, and cherished a scheme for the overthrow of the British power in India; but a stroke of apoplexy cut her off, 17th November 1796.

She was a woman of great ability, but she had in a large measure the vices of the time and station in which she lived. Her gallantries were both liberal and systematic. She always had a paramour who dwelt in her palace, and might be regarded as filling an acknowledged office of state, with large revenues and fixed privileges. Of these Potemkin (q.v.) is best remembered. Yet distinguished authors flattered her; and she invited to her court some of the literati and philosophers of France. She professed the desire to model her rule on the enlightened theories of these men, and she did effect some real improvements; but Russia was not yet in a condition to profit much from liberal opinions, and the character of the empress was not elevated enough for a government on high and just principles.

Catharine Howard. See HOWARD.

Catharine of Aragon, Queen of England, the first wife of Henry VIII., and fourth daughter of Ferdinand and Isabella, king and queen of Castile and Aragon, was born December 1485. She occupies a prominent place in English history, not for what she herself was, but for what she was the occasion of—the Reformation. Married on 14th November 1501, when scarcely sixteen, to Arthur (1486-1502), Prince of Wales, son of Henry VII., she was left a widow on 2d April, and on 25th June was betrothed to her brother-in-law Henry, as yet a boy of only eleven years old. The pope's dispensation enabling such near relatives to marry was obtained in 1504, and the marriage took place in June 1509, seven weeks after Henry's accession to the crown as Henry VIII. Between 1510 and 1518 she bore him five children, one only of whom, the Princess Mary, survived; but, though Henry was very far from being a model husband, and though he had conceived a passion for Anne Boleyn (q.v.) as early as 1522, he appears to have treated Queen Catharine with all due respect, until 1527. He now expressed doubts as to the legality of his marriage, and set about obtaining a divorce, which, all other means failing, was at length pronounced by Cranmer in May 1533 (see HENRY VIII.). Queen Catharine, who had offered a dignified passive resistance to all the proceedings, did not quit the kingdom, but took up her residence first at Amptkull, in Bedfordshire, and afterwards at Kimbolton Castle, Huntingdonshire, where she led an austere religious life until, on 7th January 1536, she died, by poison said rumour, but most likely of cancer of the heart. Queen Catharine's personal character was unimpeachable, and her disposition sweet and gentle.

Catharine Parr. See PARR.

Cathartics (Gr. *kathairō*, 'I purify'), a name originally for all medicines supposed to purify the system from the matter of disease (*materies morbi*), which was generally presumed by the ancients to exist in all cases of fever and acute disease, and to require to be separated or thrown off by the different excretions of the body. Ultimately the term cathartics became limited in its signification to remedies acting on the bowels, which are popularly called *Purgatives* (q.v.)—a mere translation of the Greek word. See also CONSTIPATION.

Cathay is the name by which the Chinese empire was commonly known in Europe during medieval times—in connection with Marco Polo's travels, for example; and Kitai is still the Russian name for China. Cathay, originally Khitai, is derived from the *Khitan*, the earliest of the northern races known to have conquered China (possibly akin to the Tunguses), who disappeared about

the beginning of the 12th century. See CHINA: and Yule, *Cathay and the Road Thither* (Hakluyt Society, 1866).

Cathcart, WILLIAM SCHAW, first Earl Cathcart, a British general and diplomatist, son of the ninth Baron Cathcart of Cathcart, Renfrewshire, was born September 17, 1755. Educated at Eton and Glasgow, and admitted an advocate in 1773, when he succeeded his father, he next year entered the army, took a prominent part in the American war, and fought with distinction in Flanders and North Germany. In 1803 he was made commander-in-chief in Ireland. In 1805 he was engaged on a diplomatic mission to Russia; in 1807 commanded the land-forces co-operating with the fleet in the attack on Copenhagen, and, for his services, was made a British peer, with the title of viscount, and received a vote of thanks from both Houses of Parliament. Sent in 1812 as ambassador to St Petersburg, he accompanied the Czar Alexander in the campaigns of 1813 and 1814, and was present at the congresses of Chatillon and Vienna. In 1814 he was raised to the rank of earl; and he died June 17, 1843.—His eldest son and successor, CHARLES MURRAY, long known as Lord Greenock, was born in 1783, served in Spain and at Waterloo, afterwards acted in Canada, and was made a general. He died 16th July 1859.—A younger son, SIR GEORGE CATHCART, was born in 1794. Educated at Eton and Edinburgh, he entered the army in 1810, served with the Russians in the campaigns of 1812 and 1813, and as aide-de-camp to the Duke of Wellington, was present at Quatre Bras and Waterloo. After helping to suppress the Canadian rebellion of 1835, and after holding the post of deputy-lieutenant of the Tower for five years, in 1852 he was made governor at the Cape, with command of the forces, and brought to a successful end the harassing Kaffir war. He returned to England in 1854 in time to be sent out to the Crimea as general of division. His bravery here was conspicuous, especially in the battle of Inkermann (November 5), where the odds were so terribly against the British, and where he fell, shot through the heart. He was buried on the spot where he fell, which in his honour was named Cathcart's Hill. Cathcart was the author of a very valuable work entitled *Commentaries on the War in Russia and Germany in 1812-13* (Lond. 1850). See vol. v. of Kinglake's *Invasion of the Crimea*.

Cathedral, from a Greek word *cathedra*, signifying a *seat*. Thus, 'to speak *ex cathedra*,' is to speak as from a *seat* of authority. The cathedral city is the seat of the bishop of the diocese, and his throne is placed in the cathedral church, which is the parish church of the whole diocese. The diocese was, in fact, anciently called *parochia*, until the application of this name to the smaller portions into which it was divided. Cathedrals vary in rank with the dignity of the see to which they belong, and may be episcopal, archiepiscopal, metropolitan, or patriarchal. Anciently only a cathedral was styled *matrix ecclesie*, but now this title is applied to all churches, even parochial only, which have other churches or chapels dependent on them. When two cathedrals are found in the same town (as is sometimes the case), they are called 'con-cathedrals.' In the Roman Church the establishment, suppression, or union of cathedrals is reserved to the pope alone. A cathedral town has generally been understood to be entitled to the honours of a city, even although the town be not a borough incorporate; but in the case of Manchester the claim was disallowed by a court of law. The distinction between cathedral and collegiate churches consists principally in the see of the bishop being at the former. The governing body

of a cathedral is called the dean and chapter—i.e. the dean and canons who meet for corporate purposes in the chapter-house of the cathedral. The property of the cathedral vests in this body. In England they elect the bishop of the diocese on the issue of a *congé d'élire* from the crown, but as the person to be elected is always named, and they may be compelled by a mandamus to elect that person and no other, the election is merely a form.

The bishop is 'visitor' of the dean and chapter, and the metropolitan is visitor of all cathedrals within his province; while the crown holds that office during the vacancy of the archbishopric. In England, all cathedrals are distinguished as being either of the old or the new foundation. The cathedrals of the old foundation are those which have from the first been served by secular canons; those of the new foundation were originally monastic churches, and served by monks. These were dissolved at the Reformation, being then re-founded on the footing of the secular churches. By the Act of 1840, all members of cathedrals, except the dean, are styled canons. Their *seat* in the cathedral is called their *stall*. They are no longer called prebendaries in most cathedrals, but this title is retained in the cathedrals of York, London, Wells, Chichester, Exeter, Hereford, Lichfield, St Davids, and St Asaph. In two cathedrals, Lincoln and Salisbury, both titles are used simultaneously, and the holders are styled 'canons and prebendaries.' In all these cases, however, the prebendaries rank below the canons residentiary, and save for their slender prebends, are on almost the same footing as the 'honorary canons' of recent institution, who have no share in the cathedral revenues or government. At St Davids the first 'curial prebend' vests in the crown, and the sovereign is senior prebendary of that cathedral. The French kings enjoyed similar privileges in six chapters, and the German emperor was *ex officio* canon of St Peter's at Rome. Canons must reside three months in each year. The Act of 1840 allows to the canons of Durham, Manchester, St Paul's, and Westminster, an income of £1000 per annum; to those of every other cathedral in England, £500. The bishop was always considered of common right to have the patronage of canonries, but formerly there were exceptions. Now, the appointment to all canonries is vested either in the bishop or in the crown. Where the bishop is patron, he 'collates,' and the dean and chapter 'induct,' by placing the new canon in a stall in the church. The crown appoints by letters-patent, and the canon is installed without collation. Honorary canons have no emoluments, but rank after the canons residentiary. Minor canons, of whom there are from two to six in each cathedral, perform the daily choral services. The cathedral service is the usual Church of England service intoned, with an anthem and the psalms chanted. For the general plan of cathedral buildings, see CHURCH. The 34 English and Welsh cathedrals are noticed under their respective cities. A pro-cathedral is a church that temporarily serves as a cathedral. See Dean Goulburn's *Cathedral System* (1871).

Cathelineau, JACQUES, leader of the Vendéans in their obstinate resistance to the French Republic, was born of humble parentage at Pin-en-Mauge, Lower Anjou, in 1759. But a poor linen-merchant at the outbreak of the Revolution in the spring of 1793, he put himself at the head of a handful of stubborn recruits, and soon became famous for the courage and success of his exploits, the greatest of which was the storming of Cholet. Spite of his own modesty, the supreme command was forced upon him after the victory of Sannur. He immediately determined to make an attack upon Nantes, and managed to penetrate into the town, but was

mortally wounded by a musket-ball, and his troops immediately dispersed. He was carried to St Florent, where he died twelve days later, July 11, 1793. Cathelineau was a man of great simplicity and honesty of character, and his piety was such that he was called the Saint of Anjou.

Catherine. See CATHARINE.

Catheter (Gr. *kathēmi*, 'I thrust into') was a name applied indifferently to all instruments for passing along mucous canals. In modern times, however, it has generally been reserved for tubular rods through which fluids or air may pass, and is now restricted to those used for emptying the urinary bladder, and those used for injecting air or fluids into the Eustachian tube (Eustachian Catheter). The catheter for the former purpose is a very old surgical instrument. The ancients made theirs of copper, which accumulated veridigris. In the 9th century silver was substituted by the Arabian surgeons as a cleaner metal, and is still used by all who are not obliged, for economical reasons, to have their catheters made of German silver or pewter. The urinary catheter for the male varies in length from 10 to 11 inches; the female catheter need not be more than 4 or 5 inches. The form is a matter of less importance, but most surgeons prefer an instrument straight to within the last few inches of its length; the latter should be curved into the segment of a small circle. Others, however, use a double curve, and indeed nearly every surgeon has a peculiar fancy in this respect. Flexible catheters are made of gum elastic (see BOUGIE), which may be used either alone or supported on a wire. Many other materials have been proposed, but vulcanised india-rubber is the only one generally in use. The Eustachian catheter is generally made of metal or vulcanite, 6 or 7 inches in length, with the last inch or less slightly curved. It is introduced into the Eustachian tube along the floor of the nose, and air or fluid, as may be necessary, forced along it by an india-rubber bag which can be attached to it. See EAR (DISEASES OF).

Cathode. See ANODE.

Catholic and Apostolic Church is the only name recognised by those often termed 'Irvingites'—a name which they repudiate as implying that they are sectarians and followers of a man. In the winter of 1829-30 the Rev. Edward Irving (q.v.), then a minister of the Scotch Church, Regent Square, London, delivered a series of lectures on spiritual gifts, in which he maintained that those which we are in the habit of calling 'extraordinary' or 'miraculous' were not meant to be confined to the primitive church, but to be continued through the whole period of the present dispensation. About the same time, as if to confirm the views of the great preacher, there occurred at Port-Glasgow, in the west of Scotland, and elsewhere, certain strange phenomena. It was alleged that miraculous acts of healing had happened, and that the gift of tongues had returned. After what seemed to be a sufficient investigation on the part of some of the members of Mr Irving's church, it was concluded that the manifestations were genuine. Similar manifestations shortly after occurred in his own church, which were also pronounced to be genuine. They were held to be of two kinds: 1st, speaking in tongues, and 2d, prophesying. As the former bore no resemblance to any language with which men were conversant, it was believed to be strictly an 'unknown tongue,' the Holy Ghost 'using the tongue of man as a sign in a manner which neither his own intellect could dictate, nor that of any other man comprehend.' The latter, 'prophesying,' consisted chiefly of 'exhortations to holiness, light upon Scripture, open-

ings of prophecy, and explanations of symbols. In 1831 Irving was deposed from his office for heresy by the Church of Scotland, but meanwhile the truths of which he was so eminent an exponent had been assuming a more definite shape. He died in 1834. It was not till July 1835 that the Catholic and Apostolic Church took definite ecclesiastical shape. With this organisation Irving had no concern, nor had he anticipated it.

The organisation comprises a fourfold ministry (Ezek. i. and Eph. iv.)—1st, 'Apostle'; 2d, 'Prophet'; 3d, 'Evangelist'; and 4th, 'Pastor.' The apostles are invested with spiritual prerogatives; they alone can minister the Holy Ghost by the laying on of hands, directly or by delegation; through them the mysteries of God are unfolded to the church; and they decide on matters of order and discipline. Nothing that occurs in any church in the way of 'prophetic utterance' can be authoritatively explained save by them; and the various 'angels of the churches' are bound to bring all such utterances under their cognisance. The function of the 'prophet' has been already indicated. The work of an 'evangelist' consists in declaring the truths of the gospel, and bringing home to the church generally the principles taught by apostles. The office of the 'pastor' is that of ministering to the help and comfort of the various members of the flock. The 'angel' of the Catholic Apostolic congregation corresponds in a limited sense to the bishop of other Christian denominations; but he has only the rank of angel-pastor in the universal church. The ministers of each full congregation comprise an angel, with a four-fold ministry (consisting of elders, prophets, evangelists, and pastors), and a ministry of deacons to give diaconal instruction and to take charge of temporal matters. The ministry is supported by tithes, the people giving a tenth of their income for the support of the priesthood. The ordinary affairs of the church are managed by the angel in a council of deacons, or if needful, of priests and deacons. The whole organisation is based on the types of the Mosaic tabernacle, in which the constitution of the Christian church is held to have been shadowed forth.

The congregation of this communion do not arrogate to themselves the title of the Catholic Apostolic Church. There is but one church built on the foundation of the apostles and prophets; the members of it throughout the world are not baptised into any section—Greek, Roman, Protestant, established, or non-established—but into the Eternal Trinity. A community of them holding the views above indicated regard themselves as a congregation of the Catholic and Apostolic Church assembling at a given place.

The Catholic and Apostolic Church does not differ from other Christian bodies in regard to the common doctrines of the Christian religion; it only accepts, in what it considers to be a fuller and more real sense, the *phenomena* of Christian life. It believes that the wonder, mystery, and miracle of the apostolic times were not accidental, but are essential to the divinely instituted church of God, and expressive of its supernatural life, whereby a people are preparing for the second advent of Christ, the hope of which is held in instant expectation. It is held that the end of this dispensation has two phases—the gathering of a first-fruits, and the subsequent great harvest, of which it is the earnest. The doctrine of Symbolism is firmly maintained, of which the most marked feature regards the mystical presence of the Lord under the elements of bread and wine, duly consecrated by the words of the institution and the presence of the Holy Ghost. Both transubstantiation and consubstantiation are repudiated. There

are services daily at 6 o'clock A.M. and 5 P.M.; prayers at 9 A.M. and 3 P.M.; the litany every Wednesday and Friday; and the eucharist is celebrated every Lord's Day, or, where there are clergy enough, daily. The liturgy, dating from 1842, is mainly based on those of the Greek, Roman and Anglican liturgies, with additional prayers. Lights and incense are used; and the vestments (surplice, alb, cope, chasuble, and stole) are similar to those of the Roman communion. The Catholic and Apostolic Church has established itself not only in the United Kingdom and its colonies, but on the Continent and in the United States.

See the *Liturgy of the Divine Offices, and The Purpose of God in Creation and Redemption* (6th ed. 1888). Miller's *History and Doctrines of Irvingism* (1878) is not authoritative, but contains much matter of interest.

Catholic Church. The term catholic literally signifies 'universal.' The phrase Catholic Church is therefore equivalent to 'universal church,' and cannot properly be applied to any particular sect or body, such as the Roman, Anglican, Genevan, Reformed, Lutheran, or Presbyterian, all of which form merely portions more or less pure of the 'church universal.' It occurs for the first time in the pseudo-Ignatian Epistle to the Smyrnaeans. It was first employed from about 160 A.D. to mark the difference between the orthodox 'universal' Christian church and the various sects of the Gnostic heretics; though, afterwards, it served also to distinguish the all-embracing Christian church from the religious exclusiveness of the pre-Christian ages, in which the church was restricted to a single nation. The formal principle of the Catholic Church is thus expressed in the famous canon of Vincentius of Lerinum (434 A.D.), 'Quod ubique, quod semper, quod ab omnibus creditum est'—i.e. the marks of the Catholic Church are *universality, antiquity, and unity*. The name has been retained by the Church of Rome, which claims to be the visible successor of the primitive one; and although Protestant divines have been careful to deny its applicability to a church which they consider essentially changed by the corrupt accretions of centuries, yet the term Catholic is still used by the populace of almost every Protestant country as synonymous with Roman Catholic, so that from their minds all conception of the literal meaning of the word has vanished. For an account of the Church of Rome, see article ROMAN CATHOLIC CHURCH.

Catholic Creditor, in the law of Scotland, is one whose debt is secured over several or the whole subjects belonging to the debtor—e.g. over two or more heritable estates. Questions of difficulty arise where one of these subjects is also burdened with other securities, but the other is burdened only with the catholic security. In such circumstances the catholic creditor is bound so to exercise his right as not unnecessarily to injure the securities of the other creditors. Thus, if he draw his whole debt from that subject on which there are other burdens postponed to his security, he must assign to the postponed creditors his security over the unburdened subject.

Catholic Emancipation. After the Reformation, both in England and in Scotland, Roman Catholics were subjected to many penal regulations and restrictions. As late as 1780 the law of England—which was actually enforced in 1764–65—made it felony in a foreign Catholic priest, and high treason in one who was a native of the kingdom, to teach the doctrines or perform divine service according to the rites of his church. Catholics were debarred from acquiring land by purchase. Persons educated abroad in the Catholic

faith were declared incapable of succeeding to real property, and their estates were forfeited to the next Protestant heir. A son or other nearest relation being a Protestant, was empowered to take possession of the estate of his Catholic father or other kinsman during his life. A Catholic was disqualified from undertaking the guardianship even of Catholic children. Catholics were excluded from the legal profession, and it was presumed that a Protestant lawyer who married a Catholic had adopted the faith of his wife. It was a capital offence for a Catholic priest to celebrate a marriage between a Protestant and Catholic. Such was the state of the law, not only in England but in Ireland, where the large majority of the population adhered to the old faith. In Scotland, also, Catholics were prohibited from purchasing or taking by succession landed property. The inexpediency and irrationality of imposing fetters of this description on persons not suspected of disloyalty, and from whom danger was no longer apprehended, began about 1778 to occupy the attention of liberal-minded statesmen; and in 1780 Sir George Saville introduced a bill for the repeal of some of the most severe disqualifications in the case of such Catholics as would submit to a proposed test. This test included an oath of allegiance to the sovereign, and abjuration of the Pretender, a declaration of disbelief in the several doctrines, that it is lawful to put individuals to death on pretence of their being heretics; that no faith is to be kept with heretics; that princes excommunicated may be deposed or put to death; and that the pope is entitled to any temporal jurisdiction within the realm. The bill, from the operation of which Scotland was exempted, eventually passed into law. An attempt which had been made at the same time to obtain a like measure of relief for the Catholics of Scotland, was defeated by an outburst of religious fanaticism. The populace of Edinburgh, stirred up by a body called 'The Committee for the Protestant Interest,' attacked and set fire to the Catholic chapel and the houses of the clergy and of such persons as were suspected to be favourable to Catholic relief. The frenzy spread to England, where a 'Protestant Association' had been formed to oppose the resolutions of the legislature (see GORDON, LORD GEORGE). In 1791 a bill was passed affording further relief to such Catholics as would sign a protest against the temporal power of the pope, and his authority to release from civil obligations; and in the following year, by the statute 33 Geo. III. chap. 44, the most highly penal of the restrictions bearing on the Scottish Catholics were removed without opposition, a form of oath and declaration being prescribed, on taking which they could freely purchase or inherit landed property.

Endeavours were made at the same time by the Irish parliament to get rid of the more important disqualifications, and place Ireland on an equality in point of religious freedom with England. In 1780 Grattan carried his resolution that the king and parliament of Ireland could alone make laws that would bind the Irish, and separation from England was urged as the alternative with repeal of the disqualifying statutes. The agitation culminated in the Irish rebellion of 1798; the union of 1800 followed, which was partly carried by means of virtual pledges given by Pitt—pledges which Pitt was unable to redeem owing to the king's scruples about his coronation oath, and Pitt resigned. Meantime, in England, Catholics continued subject to many minor disabilities which the above-mentioned acts failed to remove. They were excluded from sitting in parliament, and from enjoying numerous offices, franchises, and civil rights, by the requirement of signing the declaration against transubstantiation, the invoca-

tion of saints, and the sacrifice of the mass. In the early part of this century many measures were proposed for the removal of these disqualifications, and in 1813 and succeeding years one bill after another for this end was thrown out. Fox, Grenville, Canning, Castlereagh, and Burdett were among those who made efforts in the direction of emancipation. Meanwhile, the agitation on the subject among the Catholics themselves greatly increased, and in 1824 it assumed an organised shape by the formation of the 'Roman Catholic Association' in Ireland, with its systematic collections for the 'Catholic rent.' The Duke of Wellington, who for a long time felt great repugnance to admit the Catholic claims, was at last brought to the conviction that the security of the empire would be imperilled by further resisting them, and in 1829 a measure was introduced by the duke's ministry for Catholic emancipation. An act having been first passed for the suppression of the Roman Catholic Association which had already voted its own dissolution—the celebrated Roman Catholic Relief Bill was introduced by Peel in the House of Commons on the 5th of March, and after passing both Houses, received the royal assent on the 13th April. By this act (10 Geo. IV. chap. 7) an oath is substituted for the oaths of allegiance, supremacy, and abjuration, on taking which Catholics may sit and vote in either House of Parliament, and be admitted to most other offices from which they were before excluded. They, however, continue to be excluded from the offices of Guardian and Justice or Regent of the United Kingdom, Lord Chancellor, Lord Keeper, or Lord Commissioner of the Great Seal of Great Britain or Ireland, and Lord High Commissioner to the General Assembly of the Church of Scotland. As members of corporations they could not vote in the disposal of church property or patronage. But the public use of their insignia of office, and of episcopal titles and names, was denied them; the extension of monachism was prohibited; and it was enacted that the number of Jesuits should not be increased, and that they should henceforth be subject to registration. By the Acts 7 and 8, and 9 and 10 Viet., most of the acts still in force against Catholics were removed; 30 and 31 Viet. removed a still remaining disability, the office of Chancellor of Ireland being thrown open; though a Catholic priest may not sit in the House of Commons. For the prohibition (ultimately repealed) against the assumption of ecclesiastical titles in respect of places in the United Kingdom, see ECCLESIASTICAL TITLES ASSUMPTION ACT. See also O'CONNELL, ABJURATION, ALLEGIANCE; and the *History of Catholic Emancipation*, by W. J. Ankerst, S.J. (2 vols. 1886).

Catholic Epistles, the name given, according to Clemens Alexandrinus and Origen, to certain epistles addressed not to particular churches or individuals, but either to the church universal or to a large and indefinite circle of readers. Originally the Catholic Epistles comprised only the first epistle of John and the first of Peter, but at least as early as the 3d century, and especially after the time of Eusebius, they included also the Epistles of James, of Jude, the 2d of Peter, and the 2d and 3d of John. These seven thus constituted the Catholic Epistles, although the genuineness and authenticity of the last-mentioned five were not universally acknowledged; but the designation commended itself as supplying a convenient distinction of these letters from the fourteen bearing the name of Paul; and this very incorporation with epistles whose canonicity was not questioned, naturally had the effect of confirming their authority, so that in a short time the entire seven came to be considered a portion of the canon.

Catholics, OLD. See OLD CATHOLICS.

Catholikos is the title of the head of the Armenian Church. See ARMENIA.

Catiline, LUCIUS SERGIUS, the Roman conspirator, was born about the year 108 B.C. of an ancient patrician but impoverished family. His youth was stained with profligacy and crime. He attached himself to the party of Sulla, and revelled in the bloodshed and confusion that disgraced its triumph. His body was capable of enduring any labour or fatigue, and his mind was masterful, resolute, and remorseless. Despite his infamies he was elected praetor in the year 68 B.C., and next year governor of Africa, but was disqualified as a candidate for the consulship in 66 by charges of maladministration in his province. Disappointed thus in his ambition, and burdened with debts, he saw no hope for himself but in the chances of a political revolution, and therefore entered into a conspiracy, including many other young Roman nobles, in morals and circumstances like himself. The plot, however, was revealed to Cicero by Fulvia, mistress of one of the conspirators. Operations were to commence with the assassination of Cicero in the Campus Martius, but the latter was kept aware of every step of the conspiracy, and contrived to frustrate the whole design. In the night of November 6 (63 B.C.), Catiline assembled his confederates, and explained to them a new plan for assassinating Cicero; for bringing up the Tuscan army (which he had seduced from its allegiance), under Manlius, from the encampment at Fesulae; for setting fire to Rome, and putting to death the hostile senators and citizens. In the course of a few hours, everything was made known to Cicero. Accordingly, when the chosen assassins came to the house of the consul, on pretence of a visit, they were immediately repulsed. Two days later, Catiline with his usual reckless audacity, appeared in the senate, when Cicero—who had received intelligence that the insurrection had already broken out in Etruria—commenced the celebrated invective beginning: *Quousque tandem abutere, Catilina, patientia nostra?* ('How long now, Catiline, will you abuse our patience?') The conspirator was confounded, not by the keenness of Cicero's attack, but by the minute knowledge he displayed of the plot. His attempt at a reply was miserable, and was drowned in cries of execration. With curses on his lips, he rushed out of the senate, and escaped from Rome during the night. Catiline and Manlius were now denounced as traitors, and an army under the consul Antonius was sent against them. The conspirators who remained in Rome, of whom the chief were Lentulus and Cethegus, were at once arrested. After a great debate in the senate (December 5), in which Caesar and Cato took a leading part on opposite sides, the conspirators were condemned to death. The sentence was executed that night in prison. The insurrections in several parts of Italy were meanwhile suppressed; many who had resorted to Catiline's camp in Etruria deserted when they heard what had taken place in Rome, and his intention to proceed into Gaul was frustrated. In the beginning of January he returned by Pistoria (now Pistoja) into Etruria, where he encountered the forces under Antonius, and after a desperate battle in which he fought with more than the courage of despair, he was defeated and slain. His appearance was in the first instance that of a man of middle age, but as he grew older he became more and more like a giant. He was of a tall, muscular build, and his face was marked by a stern and almost morose expression. He was a man of great energy and courage, and his actions were always guided by a sense of duty and a desire for glory. His life was a constant struggle against the forces of corruption and decay in the Roman Republic, and his death was a great loss to the state.

Catlinarium of Sallust is perhaps the greatest masterpiece in any literature of a history in miniature.

Cat Island. See BAHAMAS.

Catkin (*amentum*). Although the vegetative growth of all inflorescences tends to be more or less shortened and compressed in consequence of their reproductive purpose, we have this peculiarly manifested in the catkin, which is a crowded spike or tuft of small unisexual flowers with reduced scale-like bracts. Examples are found in the willow, hazel, oak, birch, alder, &c. (q.v.). In some, as in the hazel and oak, the male flowers only are

1, Shoot of Birch in spring, bearing large terminal Male (*b*) and Female (*a*) Catkins. 2, Shoot of Birch in autumn with ripe Female Catkin. 3, Female Catkin of Willow.

in catkins, the female catkin of the flower being reduced to a few brown scales, while the female flowers of the oak are solitary, each on its own branchlet. Male catkins fall off after shedding their pollen, and even during life are frequently weak and pendulous, like the stamens of grasses, but these consequences of extremely reduced vegetative life become no doubt also of advantage at first in developing, and later in scattering, the pollen.

Catlin, GEORGE, one of the first authorities on the habits of the North American Indians, was born in Pennsylvania in 1796. He was bred to the law, but soon turned to drawing and painting, which he had taught himself. In 1832 he went to the Far West to study the native Indians, and spent the next eight years among them, everywhere painting portraits of individuals (not less than 470 full length) and pictures illustrative of life and manners, which are now in the National Museum at Washington. Catlin next travelled (1852-57) in South and Central America, and lived in Europe until 1871. At London in 1841 he published his learned and amply illustrated *Manners, Customs, and Condition of the North American Indians*, and in 1844 *The North American Portfolio*. He died at Jersey City, December 23, 1872. Other books are *Notes of Eight Years in Europe* (1848); *The Breath of Life, or Mal-Respiration* (1861), on the benefit of keeping one's mouth always closed.

Catmint, or CATNEP (*Nepeta Cataria*), a labiate herb, very common in North America, of which the peculiar fragrance is very attractive to cats, much in the same way as valerian.

Cato, DIONYSIUS, is the name prefixed to a little volume of moral precepts in verse, which was a great favourite during the middle ages, but the author of which is unknown. Its usual title is *Dionysii Catonis Disticha de Moribus ad Filium*. It begins with a preface addressed by the supposed author to his son, after which come fifty-six injunctions of rather a simple character, such as *parcatem ama*. Next follow 164 moral precepts, each expressed in two dactylic hexameters, the whole monotheistic in tone without being distinctly Christian. The book was early translated into most of the western languages. An English version by Benedict Burgh was printed by Caxton before 1479. A good edition is Hauthal's (Berlin, 1869).

Cato, MARCUS PORCIUS, frequently surnamed *Censorius* or *Censor*, also *Sapientis* ('the wise'), and afterwards *PRISCUS* or *MAJOR*—to distinguish him from his great-grandson, Cato of Utica—was born at Tusculum in 234 B.C. He was brought up on his father's farm in the Sabine country, and here he learned to love the simple and severe manners of his Roman forefathers. He made his first campaign in his seventeenth year, distinguished himself at the capture of Tarentum (209), at the defeat of Hasdrubal on the Metaurus (207), and in the later years of the second Punic war. At the same time he had been making himself a reputation as an orator and statesman. He became quaestor in 204, and served under the pro-consul Scipio Africanus in Sicily and Africa, denouncing his commander's luxury and extravagance on his return to Rome. He was ædile in 199, and prætor the following year, when he obtained Sardinia as his province. So high was his reputation for capacity and virtue, that in 195, although his family had hitherto been unknown, he was raised to the consulship. Spain fell to him as his province, and here he showed such vigour and military genius in crushing a formidable insurrection, that in the following year he was honoured by a triumph. In 191 he served in the campaign against Antiochus, and to him the great victory won at Thermopylae was mainly due. He now turned himself strenuously to civil affairs, and strove with all his might to stem the tide of Greek refinement and luxury, and advocate a return to a simpler and stricter social life after the ancient Roman pattern. In 187 he opposed the granting of a triumph to M. Fulvius Nobilior after his return from Ætolia victorious, on the ground that he was too indulgent to his soldiers, that he cherished literary tastes, and even kept poets in his camp. These rude prejudices of Cato were not acceptable to the senate, and his opposition was fruitless. In 184 Cato was elected censor, and discharged so rigorously the duties of his office that the epithet *Censorius*, formerly applied to all persons in the same station, became his permanent surname. He repaired the watercourses, paved the reservoirs, cleansed the drains, raised the rents paid by the publicans for the farming of the taxes, and diminished the contract prices paid by the state to the undertakers of public works. More questionable reforms were those in regard to the price of slaves, dress, furniture, equipage, and the like. Good and bad innovations he opposed with equal animosity and intolerance, and his despotism in enforcing his *own* idea of decency may be illustrated from the fact that he degraded Manilius, a man of prætorian rank, for having kissed his wife in his daughter's presence in open day.

In the year 175 Cato was sent to Carthage to arbitrate between the Carthaginians and King Masinissa, and was so impressed by the dangerous power of Carthage that ever afterwards he ended every speech in the senate-house—whatever the immediate subject might be—with the well-known words: '*Ceterum censeo Carthaginem esse delendam*'

('For the rest, I vote that Carthage must be destroyed'). Cato died in the year 149, at the age of 85. He had been twice married, and in his eightieth year his second wife bore him a son, the grandfather of Cato of Utica. Cato treated his slaves with old-fashioned harshness and cruelty, and in his old age became greedy of gain, although it cannot be said that his avarice impaired his honesty. He wrote several works, of which only the *De Re Rustica* (ed. by Keil, Leip., 1882), a kind of collection of the rules of good husbandry, has come down to us. There exist but a few fragments of his *Origines*, a summary of the Roman annals. These are reprinted by Jordan (Leip., 1860). Of his speeches, which were read with approval by Cicero, none remain. We possess his life as written by Cornelius Nepos, Plutarch, and Aurelius Victor.

Cato, MARCUS PORCIUS, named CATO THE YOUNGER, or CATO UTICENSIS (from the place of his death), was born 95 B.C. Having lost, during childhood, both parents, he was educated in the house of his uncle, M. Livius Drusus, and, even in his boyhood, gave proofs of his decision and strength of character. In the year 72 B.C. he served with distinction in the campaign against Spartacus, but without finding satisfaction in military life, though he proved himself a good soldier. From Macedonia, where he was military tribune in 67, he went to Pergamus in search of the Stoic philosopher, Athenodorus. He brought him back to his camp, and induced him to proceed with him to Rome, where he spent the time partly in philosophical studies, and partly in forensic discussions. Desirous of honestly qualifying himself for the quaestorship, he commenced to study all the financial questions connected with it. Immediately after his election he introduced, in spite of violent opposition from those interested, a rigorous reform into the treasury offices. He quitted the quaestorship at the appointed time amid general applause. In 63 B.C. he was elected tribune, and also delivered his famous speech on the conspiracy of Catiline, in which he denounced Caesar as an accomplice of that political desperado, and determined the sentence of the senate. Strongly dreading the influence of unbridled greatness, and not discerning that an imperial genius—like that of Caesar—was the only thing that could remedy the evils of that overgrown monster, the Roman Republic, he commenced a career of what now appears to us blind pragmatical opposition to the three most powerful men in Rome—Crassus, Pompey, and Caesar. Cato was a noble but strait-laced theorist, who lacked the intuition into circumstances which belongs to men like Caesar and Cromwell. His first opposition to Pompey was successful; but his opposition to Caesar's consulate for the year 59 not only failed, but even served to hasten the formation of the first triumvirate between Caesar, Pompey, and Crassus. He was afterwards forced to side with Pompey, who had withdrawn from his connection with Caesar, and become reconciled to the aristocracy. After the battle of Pharsalia (48), Cato intended to join Pompey, but hearing the news of his death, escaped into Africa, where he was elected commander by the partisans of Pompey, but resigned the post in favour of Metellus Scipio, and undertook the defence of Utica. Here, when he had tidings of Caesar's decisive victory over Scipio at Thapsus (46), Cato, finding that his troops were wholly intimidated, advised the Roman senators and knights to escape from Utica, and make terms with the victor, but prohibited all intercessions on his own behalf. He resolved to die rather than surrender, and, after spending the night in reading Plato's *Phædo*, committed suicide by stabbing himself in the breast.

His example was more fruitful in results than the achievements of his life, for he became the typical example of the stoic that kindled to imitation the imaginations of the noblest Romans for two centuries under the empire.

Cat-o'-nine-tails. See FLOGGING.

Catoptries is that division of geometrical optics which treats of the phenomena of light incident upon the surfaces of bodies, and reflected therefrom. See OPTICS.

Cato Street Conspiracy, a plot formed in London in 1820 by a handful of crazy ruffians for the murder of Lord Castlereagh and the other ministers of the crown, so called from the place of meeting in Cato Street, Edgeware Road. As usual the plot was revealed beforehand to the police by one of the gang, and accordingly the conspirators were seized, after a short scuffle, in a stable in Cato Street. Arthur Thistlewood, the ringleader, and four of his dupes, were hanged, while five more were transported for life.

Catrail (also known as the *Picts' Work* or *Picts' Work Ditch*) is the name applied to the remains of a large earthwork, about 50 miles in length, which, beginning at Torwoodlee Hill, near the junction of the Gala Water with the Tweed, runs with a semi-circular sweep southward through the counties of Selkirk and Roxburgh to a point under Peel Fell, in the Cheviots. The earthwork consisted of a deep ditch, with a rampart on each side, and varied in breadth from 20 to 26 feet. The cultivation of land and other causes have resulted in the destruction of the ramparts in many places. The Catrail was first described by Gordon in his *Itinerarium Septentrionale* (1726), and since then has been the subject of much speculation among antiquaries. For a full description of the Catrail, see paper in *Transactions of the Berwickshire Naturalists' Club* for 1880, by James Smal, F.S.A. An account of the various theories which have been promulgated regarding the Catrail will be found in *Blackwood's Magazine* for 1888.

Cats, JACOB, a Dutch statesman and poet, was born at Brouwershaven, in Zeeland, in 1577, and after studying law at Leyden and Orleans, finally settled at Middelburg. He rose to high offices in the state, and was twice sent as ambassador to England, first in 1627, and again in 1652, while Cromwell was at the head of affairs. From this time till his death, September 1660, he lived in retirement at his villa near the Hague. Here he wrote his autobiography, which, however, was not published until 1709. As a poet, 'Father Cats' enjoyed the highest popularity. His poems are characterised by simplicity, rich fancy, clearness, homely vigour, and purity of style, and by their excellent moral tendency; while throughout are richly scattered those shrewd maxims and worldly-wise axioms which have been so dear to his practical countrymen. The most highly prized of his productions were the *Houwerlyk*, and the *Trouwing* (a series of romantic stories relating to remarkable marriages), and the *Spiegel van den Ouden en Nieuwen Tyd*. His works were first collected in a folio volume in 1658. A late edition is that by Wolterink (Dordrecht, 1878-82).

Cat's-eye, a beautiful variety of chalcedonic quartz receiving its name from the resemblance which the reflection of light from it, especially when cut *en cabochon*, or in a convex form, is supposed to exhibit to the light that seems to emanate from the interior of the eye of a cat. It has a sort of pearly appearance, and is *chatoyant*, or characterised by a fine play of light, which is supposed to result from the parallel arrangement of fine fibres of some foreign substance, such as ami-

anthus, or of minute hollow tubules similarly arranged. It is of various colours, and is obtained chiefly from India and Ceylon, but occurs also in the Harz. A chatoyant variety of felspar has been sometimes confounded with cat's-eye.

Catskill, a village of New York, U.S., on the Hudson, 34 miles SSE. of Albany by rail. Pop. 4320.

Catskill Mountains, a group of mountains in the state of New York, U.S., west of the Hudson River, and south of the Mohawk. They belong to the Appalachian system, and are continuous northward with the Helderbergs, southward with the Shawangunks, south-westward with the Delaware Mountains, and westward with a high plateau which occupies much of the region of the southern half of Western New York, and a part of the northern counties of Pennsylvania. The Catskills proper cover about 5000 sq. m., chiefly in Greene County, N.Y. Some peaks reach nearly 4000 feet in height. The mountains generally have steep and often precipitous ascents, and their summits are broad and rocky. The deep valleys or 'cloves' of this region, with almost perpendicular walls, form a remarkable scenic feature. What is known as 'the Catskill red sandstone' is regarded by most geologists as the very latest formed of the Devonian strata of North America. The mountains are well wooded, and afford many summer-resorts for the people of the larger cities. See Searing's *Land of Rip Van Winkle* (1885).

Cat's-tail. See BULRUSH.

Cat's-tail Grass. See TIMOTHY GRASS.

Cattaro, a strongly fortified port in the Austrian crown-land of Dalmatia, lies at the head of the Gulf of Cattaro, 40 miles SE. of Ragusa, under the steep Montenegrin hills. Cattaro has a cathedral, a naval school, and a population of 3000, chiefly engaged in the Montenegrin trade. At one time the capital of a small republic, the town in 1420 joined the republic of Venice, and after varied fortunes was handed over to Austria in 1814 by the treaty of Vienna.—The Gulf of Cattaro, an inlet of the Adriatic, consists of three basins or lakes, connected by straits of about half a mile in breadth. Its length is 19 miles, and its depth from 15 to 20 fathoms.

Cattegat, or KATTEGAT, the bay or arm of the sea between the east coast of Jutland and the west coast of Sweden, to the north of the Danish islands. It is connected with the Baltic Sea by the Great and Little Belt (q.v.), and by the Sound; and the Skager Rack (q.v.) connects it with the North Sea. The length of the Kattegat is about 150 miles, and its greatest breadth 85 miles. Its greatest depth is 36 fathoms, but it has numerous sand-banks; and navigation is rendered more dangerous by its strong currents and violent storms. The Danish shores are low, with stretches of sand or reefs, but the Swedish shore is very steep and rocky.

Cattermole, GEORGE, water-colour painter and book-illustrator, was born at Dickleborough, Norfolk, 8th August 1800. He began life as a topographical draftsman. At the age of sixteen he was engaged upon Britton's *English Cathedrals*, and in 1830 he visited Scotland to obtain materials for his fine series of illustrations to the Waverley Novels. He was soon known as a brilliant designer, and was largely employed by the publishers, contributing to the annuals, his best work of this class being the illustrations to his brother, the Rev. C. Cattermole's *Historical Annual*, dealing with the period of the Civil War. In 1822 he was elected an associate exhibitor, and in 1833 a member, of the Water-colour Society, to whose exhibitions he contributed 'Sir Walter Raleigh witnessing the Execution of the Earl of Essex' (1839), 'Old English

Hospitality' (1839), 'The Castle Chapel' (1840), 'The Assassination of the Regent Murray' (1843), 'Cellini defending the Castle of St Angelo' (1845), and others of his best water-colours, examples of which may be studied in the South Kensington Museum. He retired from the society in 1850, and turned his attention to oil-painting, exhibiting 'A Terrible Secret,' a work in this medium, in the Royal Academy of 1863. He died at Clapham Common, 24th July 1868. As an artist he was distinguished by great versatility, and by considerable power of grouping and composition. He was learned in costume, and his works show much dramatic feeling. He gained a first-class gold medal at the Paris Exposition of 1855, and was a member of the Royal Academy at Amsterdam, and of the Belgian Society of Water-colour Painters.

Catti, or **CHATTI**, a German people, erroneously included by Cæsar under the name Suevi (q.v.), who inhabited a country pretty nearly corresponding to the present Hesse. They took part in the general rising of the Germans under Arminius; and during the reign of Marcus Aurelius, in the end of the 2d century, they made incursions into Roman Germany and Rhetia. In the 3d century their name began to give place to that of the Franks (q.v.).

Cattle. In the United Kingdom there are twelve native breeds of cattle. England claims exactly one-half of these—namely, the Shorthorn, Hereford, Devon, Norfolk and Suffolk Red Polled, Sussex, and Longhorn breeds. There are two or three varieties of cattle in Wales, but for practical purposes they may be reckoned as one breed. Four distinct breeds have arisen in Scotland, these being the Polled Aberdeen-Angus, Galloway, Ayrshire, and West Highland breeds. The remaining one is the native breed of Ireland, the hardy little Kerry, regarded as one of the purest and truest existing representatives of the ancient *Bos longifrons*. In addition to these twelve native races, other two very useful breeds, the Jersey and Guernsey, have become domiciled in the British Isles, and there are also a few of the famous Dutch milking cows scattered over the country. These various races, with an almost endless variety of crosses between two or more of them, make up the entire cattle stock of the United Kingdom, which, according to the official agricultural returns, numbered 10,598,677 head in 1887.

The *Shorthorn* is by far the most numerous and most widely diffused. It has not inaptly been titled the 'Cosmopolitan Shorthorn.' It has found a home in almost every county in the United Kingdom. The county of Durham is generally regarded as the 'cradle' of shorthorns; indeed, they have often been spoken of both at home and abroad as the 'Durham breed.' But the valuable race of native cattle from which the improved shorthorn

The brothers Charles and Robert Colling were the first to begin the systematic improvement of the breed. In those days the 'rank and file' of shorthorn cattle were large, high-staffing cattle, good milkers, but rough in form and slow in fattening. The Collings would seem to have at once directed themselves to the improvement of the native cattle where they were most defective, and they were successful in establishing a stock of cattle of a decidedly more profitable character—wider in the rib, more symmetrical in the frame, shorter in the leg, slightly smaller in size, heavier in flesh, and more speedy in maturing and fattening. It has been said, but not established beyond contention, that in effecting this improvement the Collings made use of an infusion of blood from some of the other smaller breeds. It is more likely that they relied upon 'selection' in breeding—the mating of animals of the shorthorn breed which most nearly approached to their ideal character, and fixing the type by pursuing what is designated as 'in-and-in' breeding—i.e. mating animals which are closely related to each other, a system that is known to assist greatly in stamping or fixing peculiar features and characteristics upon races of stock. The success of the Collings was speedy and complete, for the fame of their cattle spread so rapidly that even earlier than 1810, the year of the 'first great public sale of shorthorns,' they had sold cows and bulls at £100 each, and had hired bulls for use to other breeders at premiums of from £50 to £100 a year. At Charles Colling's historical sale at Ketton in 1810, 29 cows and heifers realised an average of £140, 4s. 7d.; and 18 bulls £169, 8s. each. Eight years later, at Robert Colling's sale at Barmpton, in a time of great depression, an average of £128, 9s. 10d. was obtained for 61 animals. The sensational event of the memorable sale at Ketton was the purchase of the celebrated bull 'Comet' at the fabulous price of 1000 guineas.

The importance and interest attaching to the operations of these two great pioneer breeders will at once be understood when it is mentioned that there is not at the present day a well-bred living shorthorn in whose pedigree Colling blood does not figure prominently. Colling's successors were, on the one hand, Thomas Bates; on the other, the Booth family, whose representatives then were Thomas and John Booth. At the Ketton sale (1810) Thomas Bates purchased the two-year-old heifer 'Young Duchess' for 183 guineas. Thomas Booth bought the bull-calf 'Albion' for 60 guineas; and at the Barmpton sale (1818) his brother, John Booth, secured the yearling bull 'Pilot' for 270 guineas. With these purchases the shorthorn breed drifted into two great channels, which by degrees absorbed the main current of the race, so that for many years the terms 'Booth' and 'Bates' shorthorns have been as applicable in relation to the bovine world as Whig and Tory to the political. These two strains of Bates and Booth, as has been seen, had one common origin in Colling's blood, but in course of time they developed distinctive shapes and characteristics which in the purer representatives are still well maintained. Mr Robert Bruce, than whom there is no higher authority, thus describes the characteristics of 'Booth' and 'Bates,' speaking in the first place of 'Bates' cattle: 'They are higher standing, better milking, and perhaps gayer looking cattle than the Booths. They have as a rule more upright shoulders, flatter foreribs, opener sides, with long hindquarters less fully packed with flesh than the rival strain. As a rule their heads are clean cut and pretty wide, while the bulls have long arched muscular necks and keen tempers. The prevailing colours in this strain of blood are, generally

Fig. 1.—Shorthorn Bull and Cow.

was raised abounded freely in adjoining counties as far back as reliable history enables us to trace their career. Early in the 19th century they were also known as 'Teeswater' cattle, the first famous shorthorns having come from the valley of the Tees.

speaking, deeper than in the other, being reds and rich roans. The Booth cattle are wider, deeper, and perhaps less pretty. Their shoulders are more laid back, their forelegs and flanks deeper and better filled. They are more a beef than a milk breed, with well-packed quarters and thick loins. The sires remind one more of a fat Smithfield ox, and they move without that courage and dash so peculiar to the "Duke's" and other highly valued strains of the Bates tribes. But while these are the two great divisions of the breed, there are a great many excellent shorthorns of mixed breeding which do not show any decided leaning either to the one or the other. The prevailing colour of shorthorns is roan of varying shades, but many are red, and some white. There is a dislike to red and white in distinct spots as a colour, and quite an unreasonable objection to white.

In precocity, production of meat, and general utility, the shorthorn is unsurpassed. Other varieties may excel it in special points for peculiar purposes or in certain limited districts, but for a combination of all the more useful properties of domestic cattle and adaptability to varying conditions of soil and climate, there is no equal to the shorthorn. The facility with which the shorthorn adapts itself to changes of soil, climate, and treatment is quite remarkable, and this combined with the valuable property which it also possesses in an unequalled degree—suitability for crossing with and improving other and inferior classes of cattle—has spread the improved shorthorn far and wide, not only in its own native land, but in countries beyond the seas. In North and South America, the continent of Europe, Australia, New Zealand, and other parts, the shorthorn has been extensively introduced. In all these countries, as at home, it has been one of the most active and effective agents in improving the native races of cattle and in increasing the production of high-class beef. Many breeders of shorthorn cattle have cultivated the fattening to the detriment of the milking properties. Still, while it is quite common to meet with a very light milker amongst shorthorn cows, there is a large section of the breed which possesses dairying properties of the highest order. Good shorthorn cows give from 700 to 1000 gallons of milk in twelve months. At the London Christmas Fat Stock Show in December 1887 the class of shorthorn steers under two years old (averaging 672 days) gave an average live-weight of 1396 lb.; steers over two and under three years of age (averaging 988 days), 1870 lb.; and steers over three years old (averaging 1321 days), 2116 lb. each.

Hereford cattle display strongly fixed and peculiarly distinctive characteristics both in outward features and general attributes. The improved breed traces directly from the stock of cattle which were found by the earliest writers on agricultural topics existing in the county of Hereford and adjoining districts—the same aboriginal variety from which have descended the Devon and Sussex breeds. The improvement of the Hereford would seem to have been begun by the Tomkins family far back in the 18th century, and was taken up in a systematic manner by Benjamin Tomkins about 1766, and carried on by him with much energy and success until his death in 1815. His herd was continued by his daughters till 1819 (one year later than the Barmpton sale of shorthorns), when it was dispersed by public auction. Twenty-eight breeding animals realised an average of £149 per head; four adult bulls having brought as much as £267, 15s. each; and two bull-calves £181, 2s. 6d. each. From that time the fortunes of the breed fell into other hands, and never for a moment have the Hereford stock-owners wavered in their loyalty to their fine old breed of cattle. There is

little doubt that infusions of foreign blood contributed to some extent to the building up of the modern Hereford. In the 17th century cattle had been imported into Hereford from Flanders by Lord Scudamore, and in later times there had been introductions of stock from various parts of England and Wales. The dominant ingredient, however, is the aboriginal race of the county, and selection in breeding and careful management have been the principal agencies by which the breed has been brought to the high standard it has now attained. The modern typical Hereford is red in colour, with white face and white marks in the top

Fig. 2.—Hereford Bull and Cow.

line of the neck, back over the crops, as well as in the chest and bottom line all the way backwards. The 'white face' is indeed the 'tribal badge' of the Hereford, and with their wide and graceful horns they are singularly handsome in outward appearance. Formerly there were gray-faced or spotted Herefords; and even yet there is in existence a strain of Herefords known as 'smoky-faced Montgomeries.' The Herefords are similar in size to the shorthorn; usually broad along the back and heavily fleshed, but occasionally light in the thighs and deficient in internal fat. Their highest property lies in their value as grazing cattle; and this has led to the extensive employment of Hereford bulls in breeding cattle for the rolling prairie-ranches of the western states of America. They are hardy cattle, with a rank coat of hair and thick mellow hide, and they are excellent 'foragers'—all points of special importance in ranche cattle. It is pre-eminently a beef-producing breed; matures early and yields meat of the finest quality. As a rule the cows are deficient as milkers, for this property has never been cultivated as it ought to have been. The average live-weight of two-year-old Hereford steers (averaging 634 days) at the London Christmas Fat Stock Show in December 1887 was 1390 lb.; of steers over and under three years (averaging 938 days), 1742 lb.; and of steers over three years (averaging 1310 days), 2041 lb. There are a few excellent herds of Herefords in Ireland, and they have been exported in large numbers to foreign countries, notably North and South America, Australia, and New Zealand.

Devon cattle are deep red in colour, and have frequently a white spot on the belly just in front of the udder, with wide round loins, smaller in size than the two breeds just mentioned. It is noted for the almost perfect formation of the shoulder, which is laid into the body with remarkable neatness. The breed has still its headquarters in Devon and Somerset, where it has held undisputed sway for hundreds of years. It won the admiration of Arthur Young, who gives interesting information regarding the breed in his report dated 1776. Here also there was one 'master mind' at work on the improvement of the breed. Mr Quartly of Molland is described by Young as the most celebrated of breeders in North Devon; and the greatest of our early writers on agriculture gives a most minute account of the scheme of

breeding which was pursued by Mr Quartly and his brother, 'the clergyman who interests himself much in live-stock.' The ideal animal which the Quartlys kept before them and bred up to exactly corresponds to the typical Devon of to-day; and there is no doubt that their sound and systematic method of breeding imprinted an indelible stamp upon the race through which the blood of their stock has freely permeated. In former times, when cattle were beasts of burden, the Devons were greatly esteemed for their agility and hardiness. Now that the yoke has fallen upon other shoulders, the 'Rubies of the West,' as the plump little Devons have been called by their admirers, are holding a high position as beef-producers. The quality of their meat is excelled by none; and while they are small in size, they give a good return for the food they consume. Garrard, writing in 1800, attributed the excellence of Devon cattle mainly to the mildness of the climate and high dry ground, calcareous soil, and sweet pasture where they were bred; but he considered it might be also to some extent due to an admixture of finer blood from the still warmer continent of Europe. There may have been some slight foundation for this latter suggestion; but it is undeniable that the main forces and features now existing in Devon cattle are distinctively native to the south-west of England. This idea is strengthened by the recollection of the estimate of Devon cattle formed by Bakewell, who declared that they could not be improved by any cross. From the first and greatest of all our early improvers of farm live-stock this testimony is weighty. The dairy properties of the breed are not of a high order. The yield of milk is comparatively small, but its quality is exceptionally rich. Some rare specimens of the breed have reached 19 cwt. live-weight at four years old, but the average is much below that. At the London Christmas Fat Stock Show in December 1887 the class of two-year-old Devon steers (averaging 681 days) gave an average live-weight of 1235 lb.; steers over two and under three years old (averaging 996 days), 1489 lb.; and steers over three years (averaging 1320 days), 1734 lb. each.

The *Red Polled* cattle of Norfolk and Suffolk are supposed to bear a close affinity to the polled breeds of Scotland through the circumstance that formerly Scotch cattle were freely transported to be fattened on the Norfolk pastures. Be this as it may, the red polled breed has been sufficiently long associated with Norfolk and Suffolk to enable these counties to claim them as natives. Marshall in his *Political Economy of Norfolk*, published in 1782, tells us that the native cattle of Norfolk were 'a small, hardly thriving race, fattening as freely at three years old as cattle in general do at four or five. They are small boned, short legged, round barrelled, well loined; the favourite colour a blood-red with a white or mottled face.' Arthur Young, writing in 1794, says the Suffolk breed of cattle 'is universally polled, that is, without horns; the size small; few rise when fattened to above 50 stone (14 lb.); the milk veins remarkably large; cows upon good land give a great quantity of rich milk.' These are the progenitors of the modern red polls, and all the good features of the old breed have been retained and developed. The cattle are now relatively larger, still blood-red in colour, but with no white face, good meat-producers, and, taken as a whole, perhaps the best of all the native English breeds from a dairying point of view. Individual shorthorn cows will be found to exceed them in yield of milk, but red-polled cows are distinguished for high average milking properties. The breed has found much favour in the United States of America and elsewhere abroad. Its uniformity of colour, absence of horns, and

usefulness both as beef and milk producers have won for it many hearty admirers in America.

Sussex cattle are also uniformly red in colour, with strong spreading horns, larger in size than the Devons, heavy meat-producers, but deficient in dairying properties. Marshall is probably right in stating (1796-98) that the Sussex, Devon, Hereford, North Wales, and Gloucestershire cattle had all sprung from the same aboriginal stock; and that in fact they were 'varieties arising from soils and management of the native breeds of this island.' Formerly Sussex cows were highly esteemed for their milking properties, but in the rage for beef-production these have unfortunately been destroyed. Sussex cattle mature early, grow to great weights, and in late years they have been improving in quality. They have also found supporters in foreign countries, chiefly in the United States of America. Young Sussex steers (averaging 659 days) at the London Christmas Fat Stock Show in 1887 reached an average live-weight of 1436 lb., and three-year-old steers (averaging 1349 days), 2030 lb. each.

Longhorn cattle are now in few hands; so few indeed that the breed may be said to be approaching extinction. They are big, rough, ungainly cattle, with long drooping horns which are often so shaped as to make it difficult for the animals to graze short pasture. The cows give a fair quantity of very rich milk, and the bullocks grow and fatten to great weights. But for general utility they are being ousted by smaller, finer, and more rapidly maturing varieties. Peculiar interest attaches to this breed from the fact that it was upon it that the past great improver of farm live-stock, Robert Bakewell (q.v.) of Dishley, tried his earliest experiments. The improvement of live-stock upon scientific principles dates from 1755, when Bakewell began his great work with longhorns. These cattle were at one time widely diffused through England, and also obtained a footing in Ireland, but were many years ago supplanted by shorthorns, Herefords, Devons, or other varieties.

Welsh cattle present considerable variety of type and character, yet there is all through a noticeable family likeness, arising of course in their common origin in the aboriginal cattle of the principality. They are black in colour, with long horns, hardy in constitution, good milkers, slow in maturing, but able to subsist and thrive upon scanty fare. In late years they have been considerably improved, especially in their fattening properties. They vary greatly in size, but many of them attain great weights at from three to four years old. The average live-weight of Welsh steers at the London Christmas Fat Stock Show in 1887 was 2111 lb. each, their average having been 1286 days.

Amongst the four Scotch breeds of cattle the *Polled Aberdeen-Angus* is well entitled to precedence. Descended directly from the ancient polled cattle of Angus (Forfarshire) and Buchan (in Aberdeenshire)—two varieties of the same type, known in the former as 'Doddies,' and in the latter as 'Humlies'—this valuable beef-producing breed has made great strides in public favour since 1878, when, with five plump black polls the late Mr William McCombie (1805-80) of Tillyfour carried off the champion prize for the best group of 'meat-making' cattle at the Paris Exhibition, where no fewer than sixty different varieties of cattle were represented, including the best of the English breeds. That remarkable triumph has been followed by great achievements at home, the breed having in 1881, 1885, and 1887 won the £100 Champion Plate at the London Christmas Fat Stock Show. The improvement of the breed was begun before the advent of the 19th century, and all

through its breeders have been careful to preserve and cultivate its exceptionally high properties in the production of meat of the choicest quality. In this lies the chief excellence of the breed, and in these times the characteristic is one of great value. This property in the northern polls, combined with the sound system of feeding pursued in Scotland, has secured 'prime Scotch' beef the highest favour and longest price in the London market. At one time

Fig. 3.—Polled Aberdeen-Angus Bull and Cow.

the cows of this breed gave a bountiful yield of rich milk, but owing to the breeders' attention having so long been mainly directed to the cultivation of the fattening properties, they are now only moderate milkers. In recent years the breed has improved considerably in early maturity, and at the London Fat Stock Show in December 1887 it surpassed all other breeds in this important property. At that show the class of polled Aberdeen-Angus steers under two years (averaging 667 days in age) gave an average live-weight of 1475 lb.; and steers over two and under three years (averaging 984 days), 1874 lb. Black is the prevailing colour, but occasionally a red calf is dropped.

The *Galloway* breed, which takes its name from the south-west of Scotland, where it has existed it is believed for centuries, has an undeniable claim

Fig. 4.—Galloway Bull.

to an ancient lineage. Its origin is lost in the mists of bygone ages, but enough of its history is known to insure for this breed a high position amongst the native races of British cattle. Black and hornless like the polled Aberdeen-Angus breed, Galloway cattle differ substantially from the former, not only in outward features, but also in their inherent properties. They are similar in size, more shaggy and muscular in appearance, having a thicker hide and ranker coat of hair, but they do not mature so quickly, and are not so well suited for rapid house-feeding as the northern polls. But the Galloways are excellent grazing cattle, and for this property they have been highly esteemed for many generations, both in England and Scotland. In recent years they have been exported in large numbers to America, where they have been found admirably adapted for ranching purposes. They are exceedingly robust and hardy, and have surpassed several of the other finer varieties on the ranches of the western states of America, where the cattle have to accomplish a great deal of walking in finding food and water.

From a dairy-farmer's point of view, the *Ayrshire* is the most valuable of all the British breeds of cattle. Its origin is uncertain, but it is considered more than probable that its progenitors were of Dutch extraction. Be this as it may, it was well established as a famous dairy breed in

the south-west of Scotland before the close of the 18th century. The prevailing colours are brown and white, but some are almost entirely white, others are almost a whole brown. They are wide, low-set cattle, with fine horns curving upwards. They are second-rate cattle as beef-producers, but as profitable general dairy cattle they are unsurpassed. A fairly good Ayrshire cow will give 600 gallons of milk in a year, a very large quantity for her moderate size.

There is no more handsome animal of the bovine species than a genuine representative of the *West Highland* breed. Almost as large in size as the shorthorn, and quite as well proportioned in the frame, the West Highlander gains in appearance by his rank shaggy coat of hair, long, spreading, gracefully turned horns, and hardy, muscular, and defiant gait. With the Wild White cattle of Chillingham and the tiny little Kerry of Ireland, the West Highland is regarded as the finest existing representative of the ancient cattle of Britain. The breed presents considerable variety in size and colour. Dun or yellow of various shades is the prevailing colour, but many are black or brindled. They mature slowly, but their beef is much esteemed for its quality and flavour. They are unequalled for hardiness, and can be kept with advantage where no other breed would subsist. The cattle of Orkney and Shetland differ considerably from the varieties on the mainland, but they are as a rule of an inferior character and small in size.

Fig. 5.—West Highland Cow.

The *Kerry* is the smallest of all the recognised varieties of British cattle. The breed has its headquarters in the bleak hills and upland pastures of the county from which it takes its name, and having been much neglected by Irish farmers, it forms only a very small proportion of the cattle stock of Ireland, which now mainly consists of crosses between the improved shorthorn and 'old Irish cows,' which were of mixed-bred nondescript character. Kerry cattle are very hardy, and the attributes of the Kerry cow have thus been truthfully described by Youatt: 'Truly the poor man's cow, living everywhere, hardy, yielding for her size abundance of milk of good quality, and fattening rapidly when required.' Black is the prevailing colour, and their horns are upturned and often peculiarly 'cocked.' There is a sub-variety called the 'Dexter Kerry,' shorter in the leg, thicker in body, and heavier in the flesh than the Kerry proper.

The extension of dairy-farming in the United Kingdom, and the somewhat meagre milking properties of the greater proportion of British cattle, have led to the importation of large numbers of Channel Island cattle. These—often indiscriminately called Alderney cattle—comprise the *Jersey* and *Guernsey* breeds, supposed to be from one common origin, but known to have been bred in purity in the respective islands of these names for upwards of a hundred years. They are both essentially dairy breeds, giving an abundant yield of rich highly-coloured milk. The Jersey is the smaller of the two, and is docile, delicate, and of graceful deer-like form. In the production of beef it is of little value. The Guernsey is not only larger, but also hardier and more generally useful. When in

full milk, whole herds of Jersey cows give an average of 9½ lb. of butter each cow per week, an exceptional cow occasionally giving as much as 16 lb. of

Fig. 6.—Jersey Cow.

butter in one week. Good Jersey cows yield from 500 to 700 gallons of milk, and from 300 to 350 lb. of butter in twelve months. Guernsey cows have exceeded 800 gallons of milk in a year, and the noted cow 'Select,' when six years old, gave 22½ lb. of butter in seven days, this quantity being obtained from 19 quarts

of milk per day. In America still higher records have been obtained.

It has been stated that the improvement of cattle-breeding on scientific principles was begun by Bakewell in 1755. Almost continuously since then the good work has been prosecuted with energy and success, and for many years the British Isles have been regarded as the origin and headquarters of almost all the most valuable varieties of farm live-stock. For generations foreign countries have freely resorted to these islands for improved live-stock, and this export trade goes on as briskly and as extensively as ever. The United States of America have in particular drawn very largely upon British herds, and a great stimulus to this trade with the United States has been given by the extension of the ranching system. Vast areas of grazing land in the western states and territories have been acquired by syndicates for the breeding and rearing of cattle; and with the view of improving the stock of native cattle, large numbers of well-bred bulls of the leading British varieties, either imported from the United Kingdom or descended from imported stock, have been sent to the West for use on ranches.

The cattle of the United States and Canada present almost endless variety of form and character. This is what might be expected when it is remembered that they are descended from importations of cattle from Spain, Holland, Sweden, Denmark, France, and England, Scotland, and Ireland. About the year 1525, some six years after the discovery of Mexico by the Spaniard Cortes, cattle were introduced into that country from Spain, and in the abundant pasturage of the Mexican territory they increased rapidly, spreading with the enterprising Spanish settlers into Texas, California, and other parts of the Far West. Exactly a hundred years later the Dutch settlers in New York brought cattle thither from Holland, and a few years earlier small importations of cattle had been made from the West India Islands into Virginia. The earliest of these arrivals in Virginia are assigned to 1610 and 1611, but that colony was broken up in 1622 by the Indians, who massacred 347 men, women, and children, and, it is presumed, also destroyed their cattle. In 1624—four years after the landing of the English Plymouth colony there—cattle were introduced into Massachusetts from England, and many other importations followed during the next few years. The Swedes brought cattle into Delaware in 1627, and in 1631 and two following years Danish emigrants introduced cattle from their native country into New Hampshire. English emigrants settled in Maryland in 1633, in North and South Carolina in 1660 and 1670, and in Pennsylvania in 1682, and took with them, or had sent after them, large numbers of English cattle. The French colonists brought cattle into

Quebec as early as 1608; and towards the close of the 17th century fresh importations of European cattle poured into the great American continent. It so happens, however, that while importations of cattle were made from all the countries named, and perhaps from others also, the existing cattle stock of America—leaving out the Mexican, now more commonly called Texan, cattle, which are still a race by themselves—are largely of British origin. In the earlier importations, again excluding Mexico, British cattle preponderated; and just as the English language has submerged all others in the gradual development of the American continent, so has British blood become the dominating element in the main bulk of the cattle stock of the country. There is no authentic information as to the character of the cattle first introduced into America, but all the leading breeds of the British Isles, as well as the chief milking breeds of the European continent, are now strongly represented in North America. There, as at home, the English shorthorn predominates, and there are also strong representations of the Hereford, Polled Aberdeen-Angus, Galloway, Devon, Norfolk and Suffolk Red Polls, Jersey and Dutch breeds. The cattle of America are being speedily improved, chiefly by the use of well-bred bulls, either imported from the British Isles or bred from imported cattle. Still, the majority of them are of an inferior character—quite unworthy of the rich country which they occupy. The Texan cattle still retain the rough coarse character which distinguished their Spanish ancestors. Improvement amongst the Texan cattle is proceeding very slowly.

The cattle of Australia, which are small, slow-growing, and of inferior quality as beef-producers, have also been greatly improved by the introduction of British stock, chiefly of the Shorthorn, Hereford, and Polled Aberdeen-Angus breeds.

In the management of cattle there is perhaps even greater variation than in the character of the cattle themselves. A full description of the various methods of management would itself occupy a moderate volume. It must suffice here to mention two or three leading features in cattle economy. In the British Isles the ox is no longer a beast of burden, save in a very few localities. The yoke has fallen upon the horse, except where both have been relieved by the steam-engine. The two main purposes for which cattle are now reared are the production of milk and butcher-meat. Certain breeds, as already indicated, are peculiarly adapted for milk-production, such as the Jersey and Guernsey and Ayrshire cattle; others, notably the shorthorn and red-polled breeds, are distinguished for the combination of both milking and fattening properties of the highest order; while others again, such as the Polled Aberdeen-Angus, the Hereford and Devon, &c., display remarkable aptitude to fatten, and yield meat of the choicest quality. The farmer of course selects the breed best adapted to the locality in which he lives, and to the purposes he has in view. As a rule cattle of all kinds, whether dairying or fattening, spend the summer on the pasture fields; and it is only in exceptional cases, either where there is a deficiency of grass, or where it is desired to force the growth, fattening, or milking of the animals, that any food beyond what they can pick up for themselves is given to cattle on the fields. Oil-cake, cotton-cake, and bruised grain—partly imported, mostly home grown—are the principal auxiliary foods on pasture. Where a careful system of management prevails, the cattle are put into comfortable houses overnight as soon as the chill autumnal evenings set in; and throughout the winter they are kept almost entirely in the houses, store-cattle getting out now and again about mid-day when the weather

is favourable. As winter food, turnips and straw or hay preponderate, but in the improved practice of recent years smaller quantities of roots and more of the concentrated foods, such as cake and grain, are being given to cattle. Silage is fast becoming an important article of food for cattle. Now cattle are fattened off at from eighteen to thirty months old, instead of from three to five years, as prior to 1850. The essence of the feeder's art is to produce the maximum quantity of first-class meat in the shortest possible time and at the lowest possible cost; and in the struggle after this the maturing and fattening properties of cattle have been greatly accelerated. The young or 'baby-beef,' as it has been called, is more tender and perhaps more palatable than the substantial 'rounds' of the slow-growing five-year-old heaves of 'fifty years ago'; but it is questionable if it is either so wholesome or so strength-giving. Be that as it may, the popular taste is entirely in favour of the 'baby-beef'; and what the public desire the feeder must endeavour to supply.

Since 1880 there has been considerable growth in dairy-farming throughout the British Isles. When it is mentioned, however, that in 1887 butter to the value of £8,017,000, and cheese to the value of £4,509,000, were imported into the United Kingdom, it will be seen that there is room for still further extension. The system of management on dairy-farms varies according to the locality and objects of the farmer. Where the milk can be conveniently disposed of or despatched to towns, attention is given mainly to milk-selling, which is the least troublesome, and perhaps also the most profitable system of dairying. In other cases butter is the staple produce of the dairy; in other parts again, cheese-making is the prevailing feature. The consumption of milk as human food has vastly increased in recent years. The rate of consumption keeps on growing, and ingenious facilities are devised for bringing fresh milk from distant dairies—dairies from 50 to 60 miles distant—into towns every morning. As would be expected, the calves bred on dairy-farms get little of their mothers' milk. They are reared principally on 'milk substitutes,' either prepared at home or by firms who make the production of cattle foods their sole or chief business. Linseed in various forms is very extensively used in calf-rearing.

Cattle are very variously used, and are the only or the chief beasts of draught in many countries, as Cape Colony and large part of America. In India also horned cattle are the only beasts used for ploughing, and are chiefly valued as draught animals. A famous breed was formed for military purposes; and in the Central Provinces there is a high-class breed of trotting bullocks. The best ghee of India is obtained from the milk not of cows but of buffaloes. In China, no use whatever is made of cow's milk, though human milk is sometimes given to old people as a restorative. Nearer home, in Italy even, milk and butter are but little used, and cows are in request mainly for rearing calves. The large Italian breed can do little more than feed their young; and milch cows, if wanted, are brought from Switzerland. In Italy and some other countries, cattle are all stall-fed, vine, elm, and oak leaves forming an important part of their food.

Wild Cattle.—In various parts of the world, species occur of cattle more or less wild, which are certainly different from any of the domesticated European breeds. Such are the Banteng (*Bos banteng*), the Gaur Ox (*B. gaurus*), the Zebu (*B. indicus*). But besides these extra-European wild cattle, there are abundant remains of three virtually extinct European species, from which the domesticated breeds are believed to have gradually

originated. These are *B. primigenius*, *B. longifrons*, *B. frontosus*. The first became virtually extinct within historic times, is known as the *Ur* in the Nibelungenlied, was domesticated in Switzerland in the Neolithic period, was common in Britain and on the Continent in the time of Caesar, seems to have persisted in Poland till the 17th century, and still survives in a semi-wild stage, 'though much degenerated in size,' in Chillingham Park in the north of Northumberland. In 1692 the flock numbered but 28; in 1875, 62 in all. At Cadzow near Hamilton is another herd, differing somewhat from those of Chillingham, but presumed to be also representatives of a detachment of the wild cattle that roamed the Caledonian Forest. Other herds are still found at Chartley (Staffordshire), Somerford (Cheshire), and Kilmory (Argyllshire); whilst that at Gisburn (Yorkshire) became extinct in 1859, and that of Lyme (Cheshire) dwindled from 34 head in 1850 to 4 in 1875. Though the interesting survivals preserved at Chillingham 'are less altered from the true *primigenius* type than any other known breed,' there is some reason to suppose from their white colour and some other features that they are descended from a partially domesticated ancestry. As to other descendants of *B. primigenius*, which have diverged further from the primitive type, it is generally supposed that the Podolian cattle of South Russia, Hungary, &c., the larger breeds in Friesland, Holland, and other parts of the Continent, and the Pembroke breed in England, are to be referred back to the same source.

B. longifrons or *brachyceros* was a smaller animal with short body. It was domesticated in Switzerland in the Neolithic period; it was early introduced into Britain (vast quantities of its bones having been found in remains of a lake-dwelling at Croyland); and it has its probable descendants in some of the mountain breeds of Switzerland, the Tyrol, and Bavaria (e.g. the Appenzell cattle), and, according to Owen, in some of the Welsh and Highland cattle.

B. frontosus is found along with the latter species, to which it is closely allied. It occurs in the peat-mosses of Scandinavia, and also in Ireland. It is regarded as the probable ancestor of the Norwegian mountain cattle, of the Bern cattle, and, according to Owen and others, of some of the Scotch Highland varieties. In regard to many of these pedigrees, dogmatic statement is quite impossible, and much difference of opinion obtains. The most divergent opinion is that of Wilkens, who maintains that some of the European domestic breeds are descended from the European bison.

Darwin's *Animals and Plants under Domestication*, vol. i., may be conveniently consulted for facts and references. See the articles BOVINE, BREED, BULL-FIGHT, GAUR, MUSK OX, RANCHING, YAK, ZEBU, &c. The diseases of cattle are discussed under their own heads—CATTLE-PLAGUE, PLEURO-PNEUMONIA, FOOT AND MOUTH DISEASE, ANTHRAX, BLACK QUARTER, &c.; the law thereof under CONTAGIOUS DISEASES. See G. Fleming's *Animal Plagues* (1871-82). For the management of the DAIRY, see that head, as also BUTTER, CHEESE, and MILK; on cattle generally, see Pringle's *Live Stock of the Farm*; Wallace's *Farm Live Stock of Great Britain*; Stephen's *Book of the Farm* (new ed. by Macdonald); and Allen's *American Cattle* (New York). For Wild Cattle, see Wilkens, *Rinderrassen Mittel-Europas* (Vienna, 1876); J. A. Smith, *Ancient Cattle of Scotland* (1873); and Harting, *Extinct British Animals* (1880).

Cattle, in English Law. See CHATTLE.

Cattle-plague (Ger. *Rinderpest*; Lat. *Typhus Bovis Contagiosus*). This is a specific malignant and contagious fever indigenous to the Asiatic steppes of Russia, India, Persia, China, Burma, Ceylon, &c.; never occurring in Britain but as a result of direct or indirect communication with imported

cattle, or with hides and offal which have been exposed to the contagion; and is hitherto unknown in America, Australia, and New Zealand. It is essentially a disease of the bovine family (ox, aurochs, and zebu), but may be communicated to the sheep, goat, deer, camel, giraffe, antelope, gazelle, and even the peccary.

Records of fatal plagues in cattle have been handed down from very early dates, but the descriptions are so meagre that it is possible only to surmise their nature. It is probable that one of the plagues of Egypt was a form of anthrax, but in the reign of Nero (69 A.D.) Columella describes a disease which resembles cattle-plague. He says: 'The fever is present when tears are trickling down the face, when the head is carried low and heavily, and the eyes are closed; when the saliva flows from the mouth, when the respiration is shorter than in health, and seemingly embarrassed or sometimes accompanied by groaning.' About 400 A.D. Vegetius Renatus describes, under the term *Mallens*, a disease which might have been cattle-plague. In 809-10 A.D., during the wars of Charlemagne, occurred a great outbreak of cattle-plague, which spread over nearly the whole of Europe, and particularly Britain. In 1348-49 a plague broke out amongst the cattle in England, just after the black death had destroyed thousands of human beings; it seems to have been similar to cattle-plague. Even in those days the stamping-out system was understood, as the diseased cattle were slaughtered, and infected herds, and the herdsmen attending them, were kept from coming into contact with sound animals.

In 1480 another outbreak occurred which committed great devastation. It cannot be stated positively that these outbreaks were cattle-plague, as the symptoms have not been clearly handed down, but there is evidence to prove that outbreaks occurring in 1715, in 1745, and which continued until 1757, were those of the veritable plague. That of 1745 was brought from Holland either by two white calves, or by a parcel of distempered hides brought from Zealand. The disease broke out near London, continued for twelve years, and was only suppressed by most vigorous measures. It again made its appearance in 1865, and was introduced by 331 cattle shipped at Revel, and landed at Hull. Amongst these were 13 Russian cattle, the remainder of 46 which had been brought from St Petersburg and its neighbourhood. The cargo arrived on 29th May, and a lot of 146 were disposed of at Hull on the 30th. The remaining 175 were sent to London. Amongst them were 330 sheep which were sold at Hull to the butchers and killed, and all the 175 cattle except 20 were sold for killing, but the remaining 20 were sent to Gosport. From this source the disease spread rapidly, and by the end of July it appeared in Aberdeenshire, brought by 4 calves sent to Huntly from the south. By the beginning of November the plague was present in 30 counties in England, 17 in Scotland, and 1 in Wales; and on December 30 the disease had appeared on 7443 farms or in cattle-sheds in England, 2065 in Scotland, and 245 in Wales; total—9753 centres of infection. The total number of cattle on farms, in sheds, or other places where the disease had been officially reported to exist, was—England, 110,647; Scotland, 44,527; Wales, 4536; total, 159,710. And the number of healthy animals in contact and slaughtered were—England, 10,636; Scotland, 6578; Wales, 152; total, 17,366. The number attacked were—England, 48,964; Scotland, 22,298; Wales, 2287; total, 73,549. Out of this number 7045 recovered, 41,491 died, 13,931 were killed, and 11,082 remained diseased at this date. The plague continued to spread and to commit great havoc,

until an Order in Council was issued making it compulsory to slaughter and bury all diseased cattle, as well as those which had been in contact with them. The beneficial effect of this order was soon made apparent, as the disease gradually diminished and eventually died out.

Had the restrictions upon cattle traffic been removed, there would have been another visitation in 1872, for in July of that year, animals affected with the disease were sent to Deptford, Hull, and Leith, but owing to its swift recognition, were not allowed to land in Scotland. From Hull, however, it spread to Bridlington, Pocklington, and two other parishes in the East Riding of Yorkshire, but through the activity of the authorities was prevented from spreading further.

Sheep do not readily take the disease when kept in fields with affected cattle, but if kept together in close sheds, they take the disease in a short time.

Symptoms.—The virus absorbed into the blood gives rise to elevation of temperature (fever), which precedes all other symptoms, and occurs in from 36 to 48 hours after an animal has been inoculated. It will be thus seen that the period of latency-incubation is very short. Two days after this elevation of temperature, the mucous membrane of the mouth, as well as that of the vagina in the cow, assumes a salmon colour, and is covered with an eruption. Even at this time the pulse is but little affected, but on the fourth day from the first rise of temperature there are marked signs of illness; the constitution is thoroughly invaded, and now ensue the drooping head, hanging ears, distressed look, with rigors and twitching of the muscles, failing pulse, oppressed breathing, diarrhoea, fetid breath, discharge from the eyes, nose, and mouth, and constant moan so characteristic of this dreadful malady; death usually occurs on the seventh day from the first perceptible elevation of temperature, but the third or fourth after the illness is apparent to ordinary observers.

The Virus.—It is now supposed that the disease is due to micrococci found by Klebs in 1872, and by Semmer in 1874, in the lymphatic glands and blood. The micrococci, which will grow rapidly in beef-broth and other special preparations, form zoogloea and chains; calves inoculated with them die from the plague in seven days. By repeated cultivations the virus loses its potency; inoculated into sheep it secures their immunity from the disease.

No medicinal treatment has as yet been found beneficial in this disease. Almost every remedy was tried in 1865, and although there were recoveries, no one attributed these to any remedies. The disease is much milder in cattle indigenous to those countries where it has its home and origin, and there the mortality is not great; but this mild type propagates the disease in its most virulent form when introduced amongst cattle of other countries.

Catto'lica, a town of Sicily, with sulphur-works, 14 miles NW. of Girgenti. Pop. 6591.

Catullus, GAIUS VALERIUS, the greatest lyric poet of ancient Italy, and one of the greatest poets of all ages, was born at Verona either in 87 or, more probably, in 84 B.C. Few of the incidents in his life are known to us, and the dates assigned to these are in most cases only conjectural. He appears to have belonged to the equestrian order, and his years were spent mainly at Rome, where he settled about 62 B.C., and at his villas, to which he was fond of retiring, at Tibur and Sirmio. He began to write verses when a boy of sixteen or seventeen. 'When my primrose youth was in its

pleasant spring,' he says, 'I played enough at rhyming.' In Rome he mingled with the best society, becoming intimate with the two Ciceros, the Metelli, Hortensius, and probably with Lucretius. And in Rome he met the lady whom, under the name of Lesbia, he has sung in verses which stand at the head of the lyric poetry of passion. It is almost certain that the Lesbia of Catullus was none other than Clodia, the sister of Cicero's enemy, Publius Clodius Pulcher. One of the most beautiful and accomplished women of her time, she inspired Catullus with a passionate love of which the changing phases are mirrored in a wonderful cycle of poems. There is first a time of rapturous joy; then come doubts, quarrels, and reconciliations, and in the end betrayal and despair. The final rupture seems to have happened in 57 B.C., and in that year Catullus accompanied the propretor Gaius Memmius to his province of Bithynia. He returned to Rome disappointed in his hopes of enriching himself, and entered impetuously into the contest which was then being waged between the senatorian and the democratic parties. Like Cicero and most of the men of letters of his day, he espoused the cause of the senate. A fiery, unscrupulous partisan, he assailed his enemies with equal scurrility and wit, and directed one of his coarsest lampoons at the head of Julius Caesar. His closing years were darkened by the loss of a favourite brother, on whose tomb in the Trual, which he visited when returning from Bithynia, he wrote one of the most exquisite of all poems that breathe regret for the dead. He was himself cut off in early life, for, though the exact date of his death can only be conjectured, in all probability he did not survive the year 54 B.C.

The extant works of Catullus comprise 116 pieces, many of which are extremely brief, while the longest of them contains only some 400 lines. There is considerable variety, however, in this somewhat slender body of poetry. There are graceful, playful verses of society, and there are verses, struck out in the heat of party warfare, in which satiric wit sparkles through fescennine railery. There are elaborate descriptive and mythological pieces, such as the *Coma Berenices* and the stately and richly-coloured *Peleus and Thetis*, which appear to have been translated or adapted from the Greek. There is the *Atys*, a strange poem, unlike any other work of a Latin writer in its wild imaginative power and in the magnificent sound and sweep of its galliambic verse. And there is the crowning series of love-poems, in which the incarnation of burning passion in exquisite language, the mastery of verbal music, are carried to what is seemingly the highest attainable point of perfection. In these 'Lesbia poems' there is no sign of the laborious art which produced the mosaic-work of the Horatian odes. They seem to have flowed forth—thought, feeling, phrase, and cadence combined in a perfect whole—at a single creative impulse. Their author's mastery of the Latin tongue was unerring and unbounded. In his works it seems endowed with the elastic and radiant strength of the Greek. He revealed all it had of energy, sonority, and sweetness, of monumental dignity and laughing grace. He moulded it into lines which neither Lucretius nor Virgil has surpassed for majesty of rhythm; he wove it into lyrics which for lightness of movement and caressing sweetness of cadence are unmatched in all the fields of Latin verse. For breadth of vision, fertility of thought, insight into human character, we must turn to other writers than Catullus. For fire and music and unlaboured felicity of phrase he has no superior among the lyric poets of all time.

The text of the works of Catullus, after having been lost for more than three hundred years, was discovered in the 14th century at Verona. The original manuscript was again lost, and until lately only one copy of it, which was preserved at St Germain, and is now in Paris, was believed to be in existence. A manuscript in the Bodleian Library, however, has been discovered by Dr Böhrens to be a sister copy of the St Germain manuscript. A commentary on Catullus was issued by Doering in 1788-92. The best editions are those of Mr Robinson Ellis (1866-67), and Böhrens's (Leip. 1876-85). Among the English verse translations may be mentioned those of Martin (1861), Craunstoun (1867), and Ellis (1867, and 1871). See R. Ellis's edition, mentioned above, and its admirable commentary (1876); Munro's *Criticisms and Elucidations of Catullus* (1878); and Sellar's *Roman Poets of the Republic* (new ed. 1881).

Caub, a town in the Prussian province of Hesse-Nassau, on the right bank of the Rhine, 30 miles WNW. of Wiesbaden by rail. Here Blücher crossed the Rhine with his army, January 1, 1814; and here, too, till 1866, toll was levied by the Duke of Nassau—the only ruler who kept up this feudal privilege—from vessels navigating the Rhine. Caub has underground slate-quarries; and opposite, on an island in the river, where Louis le Débonnaire died in 840, is a castle called the Pfalz, built in 1326, which is said to have been resorted to for safety by the Countesses Palatine during childhood. In 1876 and 1879 Caub was the scene of two serious landslips. Pop. 2179.

Cauca, a river of Colombia, in South America, which, after a northerly course of 600 miles, falls into the Magdalena. Its valley is one of the richest and most populous districts of the continent, and it gives name to the largest of the Colombian states, traversed by the Andean coast-range, and extending along the Pacific from Panama to Ecuador. Area, 260,000 sq. m.; pop. (1887) stated at 435,690. It is rich in minerals, and possesses the most productive platinum mine in America. Capital, Popayán.

Caucasus and the **Caucasians**. The great mountain-range of the Caucasus forms the backbone of a well-marked geographical region, nearly corresponding with the Russian governor-generalship or lieutenantancy of Caucasia. The natural and administrative northern limit is the great Manitch depression, extending from the Sea of Azov to the Caspian, and including the basins of the Kuban and Terek rivers. The southern natural limit is along the basins of the Rion and Kur rivers. The Russian province comprises all the Russian territory to the Turkish and Persian frontiers, including also part of the Armenian highlands and the mountain masses adjoining them, now known by the infelicitous name of Little Caucasus, south of the Rion and Kur rivers. Little or Anti-Caucasus is connected with Caucasus proper by the narrow Mesk ridge crossing the Rion-Kur Valley between the headwaters of those streams. The Sea of Azov and the Caspian seem at one time to have been connected by the Manitch depression; south of which extend vast steppes of flat treeless land—fertile, but with little or no water. South of the steppe to the northern spurs of the mountains is luxuriant park land covered with magnificent grasses, and also quite level. Beyond this rise the mountains in successive terraces. On the south side, towards the Rion and Kur, the mountain face is much steeper and more sudden.

The Caucasus occupies the isthmus between the Black Sea and the Caspian, its general direction being from west-north-west to east-south-east.

From the peninsula of Taman on the Black Sea, to the peninsula of Apsheron on the Caspian, it has a length of about 750 miles. The breadth, including the secondary ranges and spurs, is about 150 miles, but that of the higher Caucasus does not exceed 70 miles. This range is sometimes treated as part of the boundary line between Europe and Asia, but the region is really Asiatic in character (see ASIA). The higher and central part of the range is formed of parallel chains, not separated by deep and wide valleys, but remarkably connected by elevated plateaus, which are traversed by narrow fissures of extreme depth. The highest peaks are in the most central ridge or chain, at least six of them well over 16,000 feet, much exceeding the highest Alps. Mount Elburz attains an elevation of 18,000 feet above the sea; Kazbek reaches a height of more than 16,500 feet; and between these come Koshtan-tau and Dikh-tau. Here the line of perpetual snow is between 10,000 and 11,000 feet high; but the whole amount of perpetual snow is not great, nor are the glaciers very large or numerous. For more than 100 miles' length of the main ridge there are no passes lower than 10,000 feet. The central chain, in its highest part at least, is granitic or even pure granite. On either side of the granitic axis are metamorphic rocks, such as mica-schists and talc-schists; and beyond these, clay-slates and schists. The secondary parallel chains on both sides of the central ridge are of limestone. The spurs and outlying mountains or hills are of less extent and importance than those of almost any other mountain-range of similar magnitude, subsiding as they do until they are only about 200 feet high along the shores of the Black Sea. Some parts are entirely destitute of wood, but other parts are very densely wooded, and the secondary ranges near the Black Sea exhibit most magnificent forests of oak, beech, ash, maple, and walnut; grain is cultivated in some parts to a height of 8000 feet, while in the lower valleys rice, tobacco, cotton, indigo, &c. are produced. As might be expected from the geographical situation of the Caucasus, the climate, though it is generally healthy, is very different on the northern and southern sides, the vine growing wild in great abundance on the south, which is not the case on the north. The south declivity of the mountains towards Georgia presents much exceedingly beautiful and romantic scenery.

There are no active volcanoes in Mount Caucasus, but every evidence of volcanic action. Elburz and Kazbek are both of volcanic origin. There are hot springs and mud volcanoes at each end of the range, and there are also famous petroleum wells in the peninsula of Apsheron (see BAKU). Mineral springs also occur in many places, notably at Vladikavkaz. The bison, or aurochs, is found in the mountains; bears, wolves, and jackals are among the carnivorous animals. Lead, iron, sulphur, coal, and copper are found.

The waters of the Caucasus flow into four principal rivers—the Kuban and the Rion or Faz (the *Phasis* of the ancients), which flow into the Black Sea; and the Terek and the Kur, which flow into the Caspian. Kuban and Terek are north, Rion and Kur or Kura south of the mountains. The Russians have with great labour carried a military road through a valley somewhat wider than most of the Caucasian valleys. This is the tremendous fissure or ravine of the Dariel gorge about half-way from the Black Sea to the Caspian. The road passes over a height of about 8000 feet, and is protected by many forts. The only other road is by the Pass of Derbent, near the Caspian Sea. There is a railway from Baku by Tiflis to Poti and Batoum; Vladikavkaz is the terminus of the railway from the north.

CAUCASIAN was the name adopted by Blumen-

bach (q.v.) for one of his main ethnological divisions of mankind; and as the Georgian skull he had was the finest in his collection, the Caucasian was taken as the finest type of the Indo-European stock. Subsequent ethnologists have, mainly on philological grounds, broken up the Caucasian variety of Blumenbach into two well-marked philological groups, the Aryan (q.v.) and the Semitic peoples (q.v.). The name Caucasian was clearly a misnomer when it suggested affinity in blood or in language between the very various races of the Caucasus, classified below, and Aryans or Semites; and Prichard and others proposed actually to connect most of the Caucasus peoples with the Mongolian races of Asia. Later anthropologists, finding the word convenient, use Caucasian or Caucasoid for the Fair type of man as opposed to the Mongolic or Yellow type. But they distinctly repudiate any suggestion of community of race or of language between the peoples so named; and desire to indicate a physical fact and an anthropological type. See ETHNOLOGY; also PHILOLOGY.

The Caucasus has been called the Mountain of Languages from the multiplicity of tongues spoken in this narrow area—tongues many of them totally distinct from one another, and, with one exception, apparently unconnected with the languages of any other part of the globe, or race of men; though both Aryan and Turkoman affinities have been alleged for Georgian, and Sayce has suggested that the ancient Hittites (q.v.), whose empire in Asia Minor rivalled that of the Assyrians, were of the same stock. There are certain well-marked groups amongst them, within which manifest affinity prevails. (1) The Southern division or Kartveli stock comprises the Georgians or Grusians, mainly in the upper and middle basin of the Kur; the Imeritians, west of the watershed between the Kur and Rion; the Mingrelians, farther west reaching to the Black Sea; the Gurians, south of the Rion; the Laz, on the Turkish frontiers; and the Svans or Suanetians, between the Mingrelians and the higher Caucasus. (2) The Western division contains the Tcherkess or Circassian race, formerly on the left bank of the Kuban, north of Caucasus; the Abkhazians in the narrow strip of land between the Caucasus and the Black Sea on the south; and the Kabards, north and east of Elburz. (3) The Eastern division contains the Chechens or Tchetchens on the northern slopes of the Eastern Caucasus down to the Terek; and the Lesghians farther east and south. It is doubtful whether the numerous small tribes called Lesghians have any affinity with the Tchetchens, or how far they are related to one another; only one, the Avars, have a written language, and they use Arabic characters. (4) The Ossetes or Ossetians in the centre of Caucasus, on both slopes about Kazbek, are unquestionably a race of the Aryan stock, and the language has affinity with the Persian branch; they call themselves Irun (probably meaning *Aryan*). The Kartveli group may contain 850,000 persons; the Western group, 130,000; the Eastern, 520,000; the Ossetian, 120,000. All the Caucasian languages are extremely harsh. Some of them are partially inflectional; all save the Ossetian are substantially agglutinative.

In various portions of this territory there are of course other intrusive elements of population of foreign race: Russian Slavs; Tartars; numerous Armenians; Kurds; Greeks; Tats and other Iranians or Tajiks; and a German colony from Württemberg, east of Tiflis. Not merely do the inhabitants of the Caucasus differ widely in race, but they represent great variety of stages of culture, from the indolent, music-loving Georgians to the

wild and semi-barbarous Suanetians. Christianity is the faith of some races, as the Georgians and Ossetes; Mohammedanism of a fanatical type that of others, as the Leshghians; while primitive pagan superstitions seem largely to underlie both religious professions. One Kartvelian tribe, the Khevsurs, has in some measure combined Christianity with Moslem usages.

The resistance which the Caucasian peoples for more than half a century offered to the arms of Russia attracted to them the attention of the world. But with the capture in 1859 of Shamyl, the prophet chief of the Leshghians, who for more than twenty years withstood the armies sent against him, the power of the Caucasians was shattered; by 1870 it was completely broken. The bulk of the Circassians migrated to Turkish territories in Asia or Europe; most of the Abkhazians have done the like. The ancient divisions of the country, Georgia, Imeritia, Svanetia, Mingrelia, &c., were based on tribal distinctions. These have disappeared from the Russian administrative system. According to the latter, the main range of Caucasus divides the province into Ciscaucasia, north of the mountains, and Transcaucasia to the south of them; the former comprising the governments of Stavropol, Kuban, Terek; the latter, those of Daghestan (really north of Caucasus), Sakatal, Tiflis, Kutais, Sukhum, Black Sea, Elisabethopol, Baku, and Erivan. Add Batoum and Kars (Russian Armenia), and the Transcaspiian territory, and then Caucasasia in the widest sense has an area of 308,000 sq. m., and a pop. of 6,290,000. The chief town in Ciscaucasia is Vladikavkaz; in Transcaucasia, Tiflis; the two connected by the great military road through the Caucasus. The old capital of Georgia was Mtskheta, a good specimen of a Georgian word. For Caucasus and Caucasasia, see the map of Russia, Vol. VIII., and the articles CIRCASSIANS, GEORGIA, IMERITIA, TRANSCAUCASIA, and, for the wars with Russia, SHAMYL; also Freshfield, *Travels in Central Caucasus* (1869); Cunningham, *Eastern Caucasus* (1872); Bryce, *Transcaucasia* (1878); Philipps-Wolley, *Savage Svanetia* (1883); Dingelstedt on 'Caucasian Idioms' in *Scottish Geographical Magazine* (1888); Mourier, *Contes et Légendes du Caucase* (1888).

Cauchy, AUGUSTIN LOUIS, mathematician, born in Paris, 21st August 1789, published in 1815 a *Mémoire sur la Théorie des Ondes*, which was afterwards made the basis of the undulatory theory of light. Between 1820 and 1830 he wrote several important treatises; and at Prague, where he resided as tutor to the Comte de Chambord, he published his *Mémoire sur la Dispersion de la Lumière* (1837). From 1848 to 1852 he was professor of Astronomy at Paris, but refused the oath of allegiance to Napoleon III., and lived in retirement till his death, 23d May 1857. A reissue of his works, in 26 vols., was commenced by the Academy in 1882. See his *Life* by Valson (2 vols. Paris, 1868).

Caucus, a private meeting of politicians to agree upon candidates to be proposed for an ensuing election, or to fix the business to be laid before a general meeting of their party. The term originated in America, where the caucus has taken fast root, the 'ticket,' or list of candidates for federal, state, and municipal offices, being always decided upon by the party leaders; but of late years the system has been introduced into England, and adopted by the Radicals, especially in Birmingham, though the word is there used rather for the regularly constituted party organisation. In *Notes and Queries* for 1885 there is a long discussion as to the origin of the word, which Sydney Smith used in 1818, and John Adams in 1763. Professor Skeat is inclined to refer it to an Indian source, Captain

John Smith (1600) having *Cawcauwassoughes* for the Indian councillors of Virginia, and *Caucorouse* for an Indian captain.

Cauda-galli Grit, the basement subdivision of the Devonian system of North America. The name (lit. 'cock's tail') is derived from the feathery forms of a common fossil, supposed to be a seaweed.

Caudebec, two places in the French department of Seine-Inférieure. *Caudebec les Elbeuf*, 12 miles S. by W. of Rouen, has a pop. (1886) of 11,038, and manufactures cloth. *Caudebec-en-Caux*, a pretty antique village of 2200 inhabitants, is on the Seine, 31 miles WNW. of Rouen.

Caudine Forks (*Furcula Caudine*), two high, narrow, and wooded mountain-gorges near the town of Caudium, in ancient Samnium, on the borders of Campania; noted for the defeat of the Romans in the second Samnite war (321 B.C.). See ROME.

Caul, a portion of the amnion or thin membrane enveloping the fetus, sometimes encompassing the head of a child when born, mentioned here on account of the extraordinary superstitions connected with it from very early ages almost down to the present day. It was the popular belief that children so born would turn out very fortunate, and that the caul brought fortune even to those who purchased it. This superstition was so common in the primitive church, that St Chrysostom inveighed against it in several of his homilies. In later times midwives sold the caul to advocates at high prices, as an especial means of making them eloquent, and to seamen, as an infallible preservative against drowning (cf. Dickens's *David Copperfield*). It was also supposed that the health of the person born with it could be told by the caul, which, if firm and crisp, betokened health, but if relaxed and flaccid, sickness or death (*Notes and Queries*, 1884-86). During the 17th century cauls were often advertised in the newspapers for sale—from £10 to £30 being the prices asked; and so recently as 8th May 1848, there was an advertisement in the *Times* of a caul to be sold, which 'was afloat with its late owner thirty years in all the perils of a seaman's life, and the owner died at last at the place of his birth.' The price asked was six guineas.

Caulaincourt, ARMAND DE, Duke of Vicenza, a statesman of the French empire, born at Caulaincourt (Aisne), in 1772, early distinguished himself as an officer, was made a general of division in 1805, and shortly after created Duke of Vicenza. Faithful to the last to Napoleon, he was made Minister for Foreign Affairs in 1813, and during the Hundred Days resumed the office, receiving a peerage of France, of which he was deprived after the restoration. He died in Paris, February 19, 1827. See his *Souvenirs* (1837-40).

Cauliflower, a variety of the common kale or cabbage. It was cultivated by the Greeks and Romans, but was little attended to in England till the end of the 17th century; yet prior to the French Revolution cauliflower formed an article of export from England to Holland, whilst English cauliflower seed is still preferred on the Continent. The deformed inflorescence or heads of the cauliflower only are used. Its cultivation for the supply of Covent Garden and other markets occupies the attention of the market-gardeners of London, Cornwall, Devonshire, and the Channel Islands to a very large extent during winter and spring. It is much more tender than Broccoli (q.v.), and the plants that are reared in August for the purpose of supplying the first crop of the following summer require to be protected under hand-glasses or frames during winter. They require to be freely exposed

to air in mild or comparatively mild weather, but severe frost must be prevented from entering the glasses or frames. From the middle of August to the 24th of that month, make two or three sowings at intervals of three or four days. The plants reared from these sowings are planted out, a certain portion of the strongest under hand-glasses to furnish the earliest crop; and an abundant reserve of the smaller plants are planted a few inches apart in frames, to be planted out finally in the spring in the open ground. To succeed these a sowing may be made in a hotbed in January or February; and again in March and May, plants should be reared for successional crops, these later sowings being made in the open ground. The ground must be rich and the cultivation high to produce cauliflower of first-rate quality; there is some risk, however, in having the ground too rich for the winter crop in the case of severe weather occurring; if the plants are extra luxuriant, they will the more readily succumb to frost.

Caulking, in wood shipbuilding, is the operation of driving oakum or untwisted rope into the seams of the outside planks, or of the deck planking, to render them watertight. The quantity thus driven in depends on the thickness of the planking; it varies from 1 to 13 double threads of oakum, with 1 or 2 single threads of spun yarn. The caulker first *rauns* or *recens* the seam—that is, drives a caulking-iron into it, to widen the seam as much as possible, and close any rents or fissures in the wood; he then drives in a little spun yarn or white oakum with a wood mallet and a caulking-chisel, and afterwards a much larger quantity of black or coarse oakum. The fibres are driven in until they form a densely hard mass, which not only keeps out water, but strengthens the planking. The seam is finally coated or *payed* with hot pitch or resin.

In iron or steel shipbuilding and boiler-making the term covers the operation of driving the edge of one thickness of plating firmly against the other thickness upon which it is superimposed, or to which it is adjacent, thus rendering the joints watertight. The tool employed is a specially formed chisel, struck by a metal hand-hammer; but endeavours have been made to supplant this by steam-driven machines, so far with but indifferent success.

Caulopteris, a generic name for the stems of certain extinct tree-ferns, which range from the Devonian to the Permian system. They are hollow, and covered with markings similar to the leaf-scars on recent tree-ferns.

Caura, a considerable river of Venezuela, rises among the sierras of the southern frontier, and flows NNW. to the Orinoco. On both sides stretches the territory of Caura (22,485 sq. m.), with immense forests of tonka beans.

Caus, **CAULX**, or **CAULS**, SALOMON DE, engineer, born at Dieppe in 1576, was a Protestant, and lived much in England and Germany. He was in the service of the Prince of Wales in 1612, and of the Elector Palatine, at Heidelberg, in 1614–20; but by 1623 he returned to France, and became engineer and architect to the king. He died in Paris, 6th June 1626. At Frankfort in 1615 appeared his *Raisons des Forces Mouvantes*, &c., a work in which is described an apparatus for forcing up water by a steam fountain, differing only in one detail from that of Della Porta (see **STEAM-ENGINE**). There is no reason to suppose that the apparatus ever was constructed; but on the strength of the description, Arago has claimed for De Caus the invention of the steam-engine. See the article **DE CAUS** in vol. xiv. of the *Dict. of National Biography* (1888).

Causality, or the theory of the relation between cause and effect, is one of the most intricate and important questions of philosophical doctrine. All scientific investigation is occupied with the search for the causes of given events, or for the effects of given causes, and with the generalisation of these into laws of nature. But the nature and ground of the relation between cause and effect are obscure and disputed.

The difficulty of the question is largely increased by the uncertain signification of the word cause. Thus the investigation into the cause of things, with which early Greek speculation was occupied, was really an inquiry for the ultimate constituent or element from which the variety of actual existence had proceeded; and from this inquiry the quest for a principle of change or development was only gradually distinguished. The first important step in the direction of clear discussion was made in Aristotle's doctrine of the 'four causes': the *material* cause, out of which a thing is framed; the *formal* cause, or the essence or idea of the thing; the *efficient* or active cause, by means of which it took its present form; and the *final* cause or purpose it subserves. These, it is to be observed, are not so much causes in the modern sense of the term, as principles which enter into the existence of everything. In modern science the meaning of the term is much more restricted, corresponding in some degree to what Aristotle called the efficient cause. Thus both Bacon and Descartes wished to banish the notion of final cause from the scientific interpretation of nature; and although, in Bacon's own method, science was treated as an inquiry into the form or true nature of things (corresponding thus to Aristotle's formal cause), this notion has had little influence. What Descartes sought, and what science still seeks, is the connection rather than the essence of things; and its ideal is a mechanical interpretation of nature in terms of matter and motion. In modern science cause may therefore be said to mean the explanation of change. To some extent it corresponds with Aristotle's efficient cause. But the notion of efficient cause has itself undergone a profound modification, which seems to have been carried out alongside of the formulating of the principle of the conservation of energy. The tendency in science has been to replace the notion of power or efficiency by that of order or constant sequence. The genesis and justification of the notion of efficiency are matters of dispute: whether it is an *a priori* intuition, or derived from the consciousness of the voluntary direction of attention, or from the sensations of innervation and muscular resistance. Both Berkeley and Hume directed a vigorous polemic against the doctrine of power expressed by Locke, as going beyond the observed facts of the motion of bodies, and Hume refused to see in mind any more than in matter anything else than a succession of impressions and ideas. Into the rights of this controversy it is impossible to enter here. But clearness of scientific statement has certainly been gained by the extrusion of the notion of power, and substitution for it of that of regular sequence. It is in following out this view of the *physical* as distinct from the *efficient* cause that the term comes to be defined as the aggregate of the conditions or antecedents necessary to the production of the effect: meaning by necessary conditions those conditions without which the effect either would not have existed at all, or would have been different from what it is. In popular language, however, and even in most scientific inquiries, the term cause is restricted to the one or two conditions by the intervention of which amongst other more permanent conditions

It is in this meaning of the term that science investigates causes. In doing so, it goes on the presupposition that every event or change has a cause. This has been called the Law of Universal Causation, and may be expressed by saying that the explanation of every event is to be found in antecedent conditions. Scientific investigation also presupposes the Law of the Uniformity of Nature, that the same conditions or cause will be followed (at all times and places) by the same effects. The grounds and mutual relation of these two assumptions form the chief subject of controversy in the philosophical theory of causality. It is to Hume that the credit is due of having drawn attention to the difficulties involved in the principle of causation, in such a way as to determine the whole course of subsequent philosophy. All reasoning about matters of fact, he shows, all physical science, therefore—depends on the relation between cause and effect. Yet, between the cause and the effect there is no discoverable connection. ‘There appears not, through all nature, any one instance of connection which is conceivable by us. All events seem entirely loose and separate. One event follows another; but we never can observe any tie between them. They seem conjoined, but never connected.’ Hume’s own solution of the difficulty is found in the law of mental association. ‘The mind,’ he says, ‘is carried by habit upon the appearance of one event to expect its usual attendant, and to believe that it will exist. This connection, therefore, which we feel in the mind, or customary transition of the imagination from one object to its usual attendant, is the sentiment or impression from which we form the idea of power or necessary connection. Nothing further is in the case. . . . When we say, therefore, that one object is connected with another, we mean only that they have acquired a connection in our thoughts, and give rise to this inference by which they became proofs of one another’s existence: a conclusion which is somewhat extraordinary, but which seems founded on sufficient evidence.’ The conclusion to which Hume is driven is thus that, while all reasoning about matters of fact is founded on the principle of causality, this principle has itself no other basis than the mental tendency to pass from one impression to the idea of another, owing to their constant conjunction in experience.

Hume’s argument is not without force. It exacts regard for epistemological problems, and any principle beyond experience must at least be subjected to the connection of ideas derived from the succession of ideas. But the numerous objections to his causation put forward since the question was reopened, especially by Mill, have shown that the requirements of scientific investigation, and the opposed doctrine of Kant and his philosophical successors,

A different position is given to the causal principle in Kant's philosophy. The Scottish philoso-

The most important discussions of causality are those of Hume, *Treatise of Human Nature*, book i. part iii., and *Essay Of the Idea of Necessary Connection*; Kant, *Critique of Pure Reason*; and J. S. Mill, *System of Logic*, book iii. chaps. iii.-v. There is also elaborate treatment of the subject in the works of Reid, Stewart, and Hamilton. Dr Thomas Brown's *Inquiry into the Relation of Cause and Effect* contains much acute analytical thinking.

Causerie, a name applied to a somewhat short and informal essay on any subject in a newspaper or magazine. More familiar in manner and slighter in structure than the formal essay as usually understood, it is an excellent medium for a writer whose personality interests the reader as much as the value of his thoughts. The name owes its literary currency mainly to the famous *Causeries du Lundi* of *Sainte-Beuve*; hardly less valuable examples of the category of the occasional essays in the later Matthew Arnold.

Caustics. When the incident rays are parallel to the principal axis of a reflecting concave mirror, they converge, after reflection, to a single point, called the principal focus. In the case of parabolic mirrors this is rigorously true. For, as is easily seen from the fundamental property of the para-

bola, any ray falling on the mirror parallel to the axis is reflected so as to pass *exactly* through the focus. For other mirrors it is approximately true only when the breadth of the mirror is very small in comparison with its radius of curvature. When the breadth of the mirror is large in comparison with its radius of curvature there is no definite image, even of a luminous point. In such cases the image is spread over what is called a *Caustic*, or sometimes a *Catacaustic*.

An example of the caustic is given in the annexed figure for the simplest case—namely, that of rays falling directly on a concave spherical mirror, BAB', from a point so distant as to be practically parallel.

Two very near rays, P and Q, will after reflection intersect at C. By finding in this way all the points of intersection of the reflected rays, we get a continuous curve, BCFB', which is the section of the caustic surface by a plane passing through its axis.

The curve BCFB' varies of course with the form of the reflecting surface. In the case under consideration it is known as an *epicycloid*.

The reader may see a *catacaustic* on the surface of tea in a tea-cup half full by holding the circular rim to the sun's light. The space within the caustic curve is all brighter than that without, as it clearly should be, as all the light reflected affects that space, while no point without the curve is affected by more than the light reflected from half of the surface. The rainbow, it may be mentioned, forms one of the most interesting of the whole family of caustics.

When a caustic is produced by refraction, it is sometimes called a *Diacaustic*. No such simple example can be given of the diacaustic curve as that above given of the catacaustic. It is only in the simplest cases that the curve takes a recognisable form. In the case of refraction at a plane surface, it can be shown that the diacaustic curve is the evolute either of the hyperbola or ellipse, according as the refractive index of the medium is greater or less than unity.

Cauterets, a fashionable French watering-place in the department of Hautes-Pyrénées, lies 3250 feet above sea-level, in the valley of the Lavedan, 5 miles S. of Pierrefitte, the nearest railway station, and 42 SSE. of Pau. The stationary population was (1886) only 1468, but it is annually swelled in summer by 15,000 to 20,000 visitors, for whose accommodation numerous sumptuous hotels and bathing-establishments have been built. It is a good centre and guide-station for ascents among the Pyrenees. The sulphurous springs, twenty-five in number, and varying in temperature from 60° to 131° F., are the most abundant in the Pyrenees (330,000 gallons per day), and have been known from Roman times; though their modern reputation dates from the 16th century, when Margaret, sister of Francis I., held her literary court and wrote much of her *Heptameron* at Cauterets.

Cautery (Gr. *kaio*, 'I burn'), in Medicine, is used of any substance which burns the tissues. (The term 'potential cautery,' as applied to caustic substances, is becoming obsolete.) The *actual cautery* is an instrument with a head or blade of steel, iron, or platinum, which is heated in a fire or spirit-lamp. In the *thermo-cautery* (or Paquelin's cautery, from its inventor), the head or blade is

made of hollow platinum, so arranged that a flame of benzole can be kept burning in its interior. The *galvano-cautery* consists essentially of a platinum wire which can be heated to any required degree by passing a strong galvanic current through it. The cautery is used for three main purposes in surgery: to produce *counter-irritation* over an inflamed part (see BLISTER) (actual cautery); to check bleeding (actual or thermo-cautery), by slowly destroying the tissues at the bleeding point or surface; to perform operations, where the tissues to be divided are either very vascular (thermo-cautery), or very difficult of access (galvano-cautery). See CAUSTIC.

Caution, in the Law of Scotland, like Guaranty (q.v.) in England, is an obligation undertaken by a second party, whereby he binds himself, failing the primary obligant, to fulfil his obligation, whether it be of a pecuniary nature or otherwise. Cautionary obligations are thus essentially of an accessory nature, and cannot subsist apart from the principal obligation. The law of this subject is now largely founded on the Mercantile Law Amendment Acts, 1856, which assimilate the laws of England and Scotland, and according to which the creditor may proceed at once against the cautioner, just as if he were a joint obligant, without suing the primary debtor, unless the cautioner has expressly stipulated that this shall be done. The creditor, however, is in every case bound to use proper precaution in retaining and making available securities. He is not, however, bound to make the same full disclosure of material facts as in insurance, and therefore a cautioner should make careful inquiry for himself. Cautionary obligations are generally gratuitous, being, for the most part, undertaken from motives of friendship; but it is by no means uncommon for them to be entered into in consideration of a premium paid by the person guaranteed, or by those interested in his fortunes. Where a premium is paid, the transaction becomes a mere insurance of solvency, honesty, or efficiency; and associations of great public utility (see GUARANTEE) have been formed, both in England and Scotland, for the purpose of undertaking to guarantee the fidelity of persons employed either in public or private offices of trust. The tendency of judicial decisions, both in England and Scotland, for many years past, has been to require greater strictness than formerly in the constitution of cautionary obligations; and under the statutes already mentioned all such engagements must be in writing, subscribed by the person undertaking or making them, or by some person duly authorised by him, otherwise they shall have no effect. If a cautionary obligation is dependent on a condition, it will, of course, be ineffectual unless the condition be complied with. The cautioner may, in general, plead every defence which was competent to the principal debtor, and the extinction of the primary obligation extinguishes the secondary one. The cautioner is discharged by any essential charge being made on the obligation of the debtor, or in respect of the person relied on, without his assent. The statute expressly provides that changes of partnership either of creditor or debtor will extinguish the guarantee. If the creditor gives time—e.g. takes bills from the debtor of an unusual currency—that will also operate discharge. The discharge of one cautioner, moreover, unless consented to by the rest, is a discharge to all. The cautioner is entitled, on full payment, though not on payment by a dividend, to an assignation of the debt and diligence, by which means he comes, in all respects, into the creditor's place; and moreover, if the solvency or other conditions of the principal debtor should seem precarious, he may

adopt legal measures for his relief. Co-cautioners, or persons bound together, whether their obligations be embodied in one or several deeds, are entitled to mutual relief. But where a co-cautioner obtains relief from the others, he must communicate to them the benefit of any deduction or ease which may have been allowed him in paying the debt.

Letters of credit and recommendation raise much the same relation of parties as a formal cautionary obligation, but since 1856 a mere verbal introduction cannot have that effect. For the forms and effects of ordinary mercantile guarantees, and for the forms of guarantee insurance of fidelity, see GUARANTEE. For the Scottish cautionary obligation in cash-credit bond, see BANKING, II. 713.

JUDICIAL CAUTION, in the Law of Scotland, is of two kinds—for appearance, and for payment. If a creditor makes oath before a magistrate, that he believes his debtor to be meditating flight (*in meditatione fuge*), he may obtain a warrant for his apprehension; and should he succeed in proving the alleged intention to flee, he may compel him to find caution to abide the judgment of a court (*judicio sisti*). The cautioner, or surety, undertakes that the defender shall appear to answer any action that may be brought within six months. The old Bond of Presentation, by which in order to gain time the surety undertook to produce the debtor or pay the debt at a future date, is now superseded by the abolition of imprisonment for debt. There is also a form of judicial caution called *judicatum solvi*, given in cases of general loosing of arrestment of ships, in which the surety becomes liable for the whole debt. The commonest form of judicial caution, however, is the security usually given in the Bill Chamber (q.v.), when a bill or bond is brought under suspension; the security is for the principal sum and expenses, if the suspension should be refused. Interdict is also frequently granted upon caution for the damages that may result from the interdict, should it turn out to have been wrongly obtained.

Cauvery. See KAVERI.

Cava del Tirreni, a town of Italy, in a lovely valley, 5½ miles NW. of Salerno by rail, with a cathedral, and manufactures of silk, woollens, cotton, and linen. Pop. 6339. About a mile distant is the Benedictine monastery of the Trinity, celebrated for its archives.

Cavagnari, SIR LOUIS, born in France in 1841, was educated at Christ's Hospital, London, and in 1857 was naturalised as a British subject. He had seen twenty-one years' military and political service in India, when on 3d September 1879 he was murdered at Kabul. See AFGHANISTAN.

Cavaignac, LOUIS EUGÈNE, born in Paris, 15th October 1802, was a son of General Jean Baptiste Cavaignac (1762-1829), a member of the National Convention. Educated for the military profession, he first served in the Morea, and afterwards in Africa, whither he was sent in 1832 into a kind of honourable exile, in consequence of a too free expression of opinion in favour of republican institutions. Here he won great distinction by his energy, coolness, and intrepidity, was made chef de bataillon in 1837, and rose to the rank of brigade-general in 1844. In 1848 he was appointed governor-general of Algeria, but in view of the impending revolutionary dangers, was called to Paris and assumed the office of Minister of War. He was appointed military dictator in order to suppress the formidable insurrection of June, which he quelled only after a most obstinate contest continued from the 23d to the 26th June. It is estimated that a greater number of Frenchmen fell in the struggle than in the bloodiest battles of the first Empire. Cavaignac's clemency to the vanquished was equal

to his generalship. His task being done, he resigned his power into the hands of the National Assembly, which appointed him President of the Council. As a candidate for the presidency of the republic, when Louis Napoleon was elected, he received nearly a million and a half of votes out of 7,327,345. On the *coup d'état* of December 1851, Cavaignac was arrested, but released after a short detention; and though he consistently refused to give in his adhesion to the Empire, he was permitted to reside in France without molestation. He died, 28th October 1857, at his country house near Tours. Cavaignac was an able soldier, a zealous republican, and in every way an honourable man. See his *Life* by Deschamps (2 vols. Paris, 1870).

Cavaillon (ancient *Cubellio*), a town of the French department of Vaucluse, 18 miles SE. of Avignon by rail, with a cathedral, and some Roman remains. Pop. 5164.

Cavalcanti, GUIDO, Italian poet, born in 1230, was banished, for mercantile transactions with a Guelph, by the Ghibellines, a daughter of one of whose chiefs he had married, and returned in broken health to Florence only to die there, about 1300. His works—sonnets, ballads, and canzoni—are remarkable alike from their language & depth of thought, although his epicurean philosophy gained him, among his contemporaries, the reputation of an atheist. See Ercole, *Guido Cavalcante e le sue Rime* (Milan, 1885).—Another of the name, BARTOLOMMEO (1503-62), a noble and eloquent Florentine, led a revolt against the Medici, and was afterwards employed by Pope Paul III.

Cavalcaselle, GIOVANNI BATTISTA, Italian art writer, born 22d January 1820, at Legnago, early visited the art centres of Italy, and in 1846 proceeded to Germany, where he met J. A. Crowe (q.v.), with whom he returned to Italy. Banished for his share in the revolution of 1848, he accompanied Crowe to London, and there their first joint work, *Early Flemish Painters* (1857; 3d ed. 1879), was published. Cavalcaselle returned to Italy in 1858, and in 1861 commenced with Crowe the *History of Painting in Italy* (Lond. 5 vols. 1864-71). Other joint works are *Titian* (1876) and *Raphael* (1883); Cavalcaselle's independent writings are of less importance. He is head of the art department in the ministry of Public Instruction at Rome.

Cavalier (Fr., from Lat. *caballus*, 'a nag'), from 'horseman' acquired the meaning of 'knight' or 'gallant', in which sense it is used by Shakespeare (*Henry V.*, III. 24), like *caudero*, in *Henry IV., Part II.*, V. iii. 62. In 1641 'Cavaliers' was applied as a nickname to Charles's partisans in opposition to the Roundheads, or friends of the Parliament; and from a term of reproach it came to be adopted as a title of honour, until, after 1679, it was superseded by 'Tory.' For the 'Cavalier Parliament' (1661-79), see CHARLES II.

Cavaller, JEAN, a journeyman baker, from Ribaute, near Anduze, who, born in 1681, in 1702 became a famous leader of the Camisards (q.v.), withal a prophet and preacher. He surrendered to Villars in 1704, and entered the service of Savoy; but in 1711 we find him settled with a British pension in England, and he died at Chelsea, governor of Jersey, 17th May 1740. See a long article in vol. ix. of the *Dict. of National Biography* (1887).

Cavaliere Servente. See CICISBEO.

Cavalry is a general name for horse-soldiers or troopers trained to act in a body. In the British army there are 31 regiments of European, and 30 of native Indian cavalry. The former comprise 2 regiments of Life Guards (red), 1 of Horse Guards

(blue), and 7 of Dragoon Guards, classified as *heavy* cavalry; 3 regiments of Dragoons, and 5 of Lancers, classified as *medium*; and 13 Hussar regiments or *light* cavalry—all carrying carbines and swords. The war strength of each is 1 lieutenant-colonel, 1 major, 8 captains, 9 lieutenants, 7 sub-lieutenants, 1 adjutant, 1 paymaster, 1 quartermaster, 1 medical officer, 1 veterinary surgeon, 75 non-commissioned officers, 8 farriers, 8 shoeing-smiths, 8 trumpeters, 4 saddlers, 2 wheelers, 15 bandsmen, 480 troopers, and 22 drivers, 559 riding and 44 draught horses, and 11 wagons.

The native Indian cavalry are all *light*, and some have the front ranks armed with lances, the rear with sabres. Bengal has 19 regiments, each of 8 troops, consisting of 10 European officers (1 in command and 1 surgeon), 17 native officers, and 536 native non-commissioned officers and troopers. Madras has 4 regiments of only 6 troops each, the same number of European, but 12 native officers and 396 of other ranks. Bombay has 7 regiments with the same organisation and numbers as Bengal, but only 518 native non-commissioned officers and troopers. Besides these regiments there is a troop of native cavalry at Aden, and one as a body-guard for each lieutenant-governor, and the governor-general of India.

The auxiliary cavalry in Great Britain comprises 39 regiments of Yeomanry, 2 of Volunteer Light Horse, and 1 of Volunteer Mounted Rifles, of various strengths. There is a cavalry dépôt at Canterbury, and a school of instruction for auxiliary cavalry at Aldershot.

After the American civil war, the United States' cavalry was reduced to 10 regiments of 936 privates each. The commissioned officers of a regiment consist of 1 colonel, 1 lieutenant-colonel, 3 majors, 12 captains, 14 first lieutenants, and 12 second lieutenants.

History.—For the place of cavalry in the ancient armies, see ARMY. In the middle ages horsemen—knights, esquires, and their attendants—formed the most important part of the great armies; but after the disappearance of the Roman cohort with its 132 highly trained horsemen, the organisation of cavalry, as we now understand the word, was neglected until 1445, when Charles VII. of France grouped his men-at-arms into companies 100 strong. The method of fighting, from 1645 until Frederick the Great introduced the charge or shock tactics, was to advance to close quarters, fire pistols from the saddle, and then commence cutting with the sword. The value of dismounted cavalry able to act as infantry was then recognised, and dragoons armed with muskets were much in vogue until the beginning of the 19th century. They then lost favour, and though all European nations continued to train their troopers to dismount and use their carbines to hold some important point until the arrival of infantry, it was taught that the sword was their proper weapon, and the saddle their proper place. But Russia has lately armed all her cavalry, except the Cossacks, with long rifles, thus turning them into dragoons, and it is now generally felt that the dismounted service of cavalry must be developed to a greater extent than has hitherto been the case. Mounted infantry too, using their horses merely as a means of rapidly covering the ground, have been found so useful in the British army, that in 1887 a school for this arm was formed at Aldershot; and it has been decided that a force 900 strong shall accompany the cavalry division on active service.

Formation.—A cavalry regiment in the field is divided into 4 squadrons, each of 2 troops. The men of each squadron when in line are 6 inches from knee to knee, and formed in two ranks, a horse's length apart. The officers are at a similar distance

in front, and the 'serrefiles,' or supernumerary non-commissioned officers, in rear. There is an interval of 12 yards between squadrons. The pace is, walk 4 miles an hour, trot 8, gallop 12. The maximum distance covered by cavalry is 68 miles by day (6 A.M. to 10 P.M.) and 18 by night—86 for the 24 hours; but after such a march there must be a rest all next day. For a continuous march 35 miles a day, at 5 miles an hour, is a good rate.

Duties on Service.—In large armies, from one-eighth to one quarter of the whole force should be cavalry. Their duties are to cover the movements of their own army, and to find out those of the enemy—besides taking part in the actual battles by guarding the flanks, seizing all opportunities of charging, completing success by an active pursuit, or covering defeat. The screening and reconnoitring duties are performed by the cavalry divisions, each of two or more brigades, one or two days' march in front of the main body. The light Brigades (q.v.) are perhaps best for the actual scouting, but must be supported by heavy cavalry in order to meet that of the enemy, which would otherwise have the advantage of greater weight in the charge. Each brigade of two or more regiments is accompanied by a battery of Horse Artillery.

The battle of Mars la Tour in the Franco-German war of 1870, supplies the best examples of a cavalry fight on a large scale, and of a charge (that of Barby and Bredows' brigades) directed against infantry. The action of the German cavalry throughout the same campaign illustrates the screening and reconnoitring duties of the arm. The capture of Cairo by the rapid advance of the British cavalry after the battle of Tel-el-Kebir (1882), shows its value after a successful engagement.

Tactics.—Unless acting dismounted, cavalry must either attack or retire; it cannot otherwise defend itself. Against cavalry it must therefore manoeuvre with its first line, so as to attack to the best advantage—i.e. against the adversary's flank. Its second line following, *en échelon*, in order to have a clear front, protects the flanks of the first from counter attack, and supports its movement, completing its victory, or covering its retreat. Horse artillery on the protected flank fire upon the enemy up to the last moment before the charge. A third portion, formed into a reserve, follows, and behind it the other two can rally after the charge, which, even when successful, creates great confusion. Cavalry attacks artillery in two bodies—one in line formation charges the escort, and the other in extended order, the men a horse's length apart, converges upon the guns. Infantry can defend itself from a cavalry charge, unless surprised by a flank attack, which would generally be delivered by comparatively small bodies in successive lines, but such an opportunity rarely occurs on a modern battlefield.

Cavan, an inland county in the south of Ulster. It lies in the narrowest part of Ireland, 18 miles from the Atlantic, and 20 from the Irish Sea. Area, 746 sq. m., of which less than a third is under crops. Bogs and hills, with many small lakes, are found in the north-west, where Cuilcagh attains a maximum altitude of 2188 feet. The chief rivers are the Erne, the Woodford, and the Annalee. The eastern half of Cavan rests on clay-slate and graywacke; the mountain district in the west is carboniferous formation. Of minerals, Cavan affords coal, iron, lead, and copper, with many mineral springs. The climate is cold and damp; and the soil is poor, wet, and clayey, except along the streams. The chief crops are oats and potatoes, the cultivation of flax having greatly decreased since 1850. The farms are small. Agriculture forms the staple industry, but linen is manufactured to a considerable extent. The chief towns are Cavan, Cootehill, and Belturbet. Cavan returns two members to parliament. Pop. (1851)

74,064; (1881) 129,176, of whom 104,328 were Catholics, and 48,990 Episcopalians.—CAVAN, the county town, stands on a branch of the Annalee, 85 miles NW. of Dublin by rail. It has a court-house and a grammar-school; and the beautiful demesne of Lord Farnham lies between Cavan and Lough Oughter, which is about 5 miles west. Pop. (1881) 3050.

Cavatina, a short form of operatic air, of a smooth and melodious character, differing from the ordinary aria in consisting only of one part, and frequently appearing as part of a grand scena. Examples of cavatina are found in many well-known operas, as *Sonnambula* and *Les Huguenots*. The term is also often used for a complete air or song, such as the 'Salve dimora' in *Faust*.

Cave, or CAVERN (Lat. *cavus*, 'hollow'). The natural hollows which occur in and underneath rocks have originated in various ways—some being due to the chemical and mechanical action of water, others to dislocations and disruptions produced by movements of the crust, or by superficial rock-falls and landslips, while yet others are tunnels which now and again occur in or under thick sheets of lava. Caves formed by marine erosion are frequently met with along the coast-line of Britain and other countries, Fingal's Cave at Staffa (q.v.) being a splendid example. They are not confined to any particular kind of rock—although, other things being equal, they are of course more easily formed in readily yielding rocks than in more durable kinds. It is rather the character of their natural division-planes or beds and joints than their composition and texture that determines whether the rocks at the base of a sea-cliff shall be hollowed out or not by the action of the waves. If the rocks are thin-bedded and abundantly and regularly jointed, it is obvious that as soon as any portion is undermined by the sea, the overlying masses will immediately yield along their division-planes and topple down. If, on the other hand, the rocks are meagrely and irregularly jointed, and occur in massive beds, then they will not so readily collapse when undermined, and caves will tend to be formed. Caves which have had this origin are not uncommonly met with along the line of old sea-margins in many regions which have been elevated in recent geological times. Most frequently, however, the entrances to such caves are concealed by the rock-rubbish which has been detached from time to time by the action of the weather from the cliffs above. Caves of erosion are also formed by river-action at the base of crags and cliffs in many valleys. And now and again such hollows may be detected at various levels in river-cliffs, as if they had been formed during the gradual excavation of the ravines in which they occur.

In Britain and other countries long occupied by man most of such river-cliff caves or rock-shelters have been artificially deepened and widened, and this to such an extent that it is often hard to say how much of the work can be attributed to nature. By far the most important caves, however, are those which owe their origin to the action of underground water. But before these are described, mention may be made of the hollows which occur now and again in and under lava-flows. Where lava has flowed over and solidified above a mass of snow and ice, the subsequent melting of the latter will leave a hollow behind. Near the Casa Inglese, on the south-east side of the highest cone of Etna, a mass of ice of unknown extent and thickness, covered by lava, was seen by Lyell in 1828 and again in 1858. But this, it must be remembered, is at a height of 10,000 feet above the sea. In lava itself, however, caves of considerable extent occur. Many of

these are simply great blisters or hollows formed by the expansive power of the highly heated vapours contained in the lava at the time of its eruption. Others again may have been caused by the sudden conversion into steam of the water of lakes or streams suddenly overwhelmed by a lava-flow—the steam thus generated might either violently rupture the lava by its explosive force, or produce great tunnels and irregular cavities under the liquid lava, already inclosed in its solid crust, by pressing it upwards. The extensive Fossa della Palomba of Etna is supposed by some to have had such an origin. But probably the greater number of the larger caves under lava have been formed by the escape of the lava itself from its own solidified envelope. When lava pours out from a volcanic orifice it very rapidly coagulates above and below, so that the liquid rock becomes imprisoned in a hardened crust of its own material. The great pressure of the inclosed lava, however, upon the crust at the terminal point of the flow suffices again and again to rupture it, and the lava then flows out freely until it is again imprisoned in the same manner. In the case of very liquid lavas this escape is often completed in a perfect manner—and a long underground tunnel is left behind, from the roof of which depend long stalactites of black glassy lava. Extensive caves formed in this way—some of them measuring over 100 feet in width—occur in the Azores, the Canary Islands, Iceland, and other volcanic regions.

Another class of caves embraces such hollows as have originated during earthquakes or other movements in the crust of the earth. At such times rocks are rent asunder, and when they fall rudely together irregular cavities are left between the disjointed masses, and similar results often take place when great landslips occur. But the most extensive caves and underground galleries have been excavated by the chemical and mechanical action of underground water. Sometimes these hollows continue more or less persistently in one direction, but most usually they wind tortuously about, and often open into similar intricate galleries, which, in like manner, communicate with lateral extensions of the same character. There can be no doubt that caves of this kind are the channels of underground streams and rivers, and that they have been excavated, in the first place, by the chemical action of acidulated water making its way downwards from the surface along the natural division-planes of the rocks, until eventually space has been licked out for the passage of a subterranean stream. The cavities would then tend to be enlarged by the filing action of the sand and gravel which the underground stream and its numerous feeders might sweep along. Many such underground watercourses are well known at the present day, and the direction of some of them can be traced by the swallow-holes, chasms, and 'sinks,' which indicate places where the roofs of the cavities have given way, or have been pierced by the action of acidulated water. In certain regions almost all the drainage is thus conducted underground—rivers after flowing for a considerable distance at the surface suddenly disappear, and follow a hidden course, for it may be many miles, before they emerge again to the light of day. Sometimes, indeed, they never come to the surface again, but enter the sea by subterranean channels. Should anything occur (such as earthquakes, &c.) to interrupt such a system of underground drainage, and the streams and rivers be compelled into new channels, the old subterranean courses will then become galleries more or less dry, which may be accessible by one or even by several openings.

As it cannot be doubted that all such great

underground galleries owe their inception entirely to the chemical action of water seeking its way downwards from the surface, and following the lines of natural division-planes in the rocks, it is obvious that caves will be of most common occurrence in regions where the rocks yield most readily to such chemical action. Among the more soluble rocks are rock-salt and gypsum, but these are only locally developed in such quantities as to give rise on their removal to underground cavities of any extent. Calcareous rocks, more especially limestone, have not only an almost world-wide distribution, but they also occur in greater mass than either gypsum or rock-salt, and hence, although not so readily acted upon by water as the latter two, it is in limestones that nearly all the most renowned caves and subterranean galleries appear.

Many caverns have a calcareous incrustation lining their interior. Sometimes this deposit is pure white; it is, however, more generally coloured by the impurities which the water, percolating downwards from the surface, has taken up from the superincumbent rocks. To the incrustations which are suspended from the roof like icicles, the name *stalactites* is given, while those rising from the floor are called *stalagmites*. The origin of these is as follows: Water which has percolated down from the surface always contains a certain proportion of carbonic acid—it is acidulated water—the acid being derived from the atmosphere and the decaying organic matter of the soil, &c. Water thus charged with carbonic acid has the power of dissolving limestone—i.e. it takes up a certain proportion of carbonate of lime and converts it into the soluble bicarbonate. Arrived at the roof of a cave it oozes out and is there subject to evaporation, the excess of carbonic acid is parted with, and a thin pellicle of carbonate of lime is deposited as an incrustation. When the drops fall to the floor they are subject there in the same way to evaporation, and are thus compelled to give up the remainder of the calcareous matter held in solution. By this constant dropping and falling, icicle-like pendants grow downwards from the roof, while sheets, bosses, and domes gradually accumulate upon the floor—until, not infrequently, these *stalagmites* come at last to unite with the gradually lengthening *stalactites*, and so to form, as it were, pillars which look as if they had been placed to support the roof. See the articles on ADELSBERG, AGTELEK, KENT'S CAVE, MAMMOTH CAVE, &c.

BONE-CAVES.—Caves are of interest to geologists not only because they testify to the potency of the chemical and mechanical action of underground water, but on account of the remarkable evidence they have yielded as to the contemporaneity of man with many extinct and no longer indigenous mammals. This evidence is furnished by the accumulations which so frequently cover the floors of caverns to a greater or less depth. The accumulations in question consist partly of clay, sand, gravel, and shingle, and partly of red earth and sheets of stalagmite. Some of these are doubtless the alluvial detritus carried forward by underground streams. This detritus often consists largely of angular, subangular, and water-worn fragments of limestone, which have doubtless been derived from the roof and walls of the underground galleries, but not infrequently the presence of other kinds of rock-fragments shows that no inconsiderable amount of material has been introduced from the outside by the streams as they plunged into their subterranean courses. Much debris also may have been swept in by heavy rain or flooded torrents washing down through the sinks and swallow-holes that so frequently pierce the roofs of subterranean watercourses. These sinks often become pitfalls to unfortunate cattle in our own day, and in former

times many animals may have been entrapped in the same way—for broken and rubbed bones often occur, sometimes very abundantly, in the old torrential accumulations of deserted subterranean watercourses. When the galleries ceased to be traversed by streams, stalagmitic accretions would then begin to accumulate over the shingle and debris beds. In course of time many of these subterranean hollows, becoming more or less accessible from the outside, were occupied by carnivorous animals, who carried thither their prey, and thus by and by accumulations of bones were formed, which the drip of water from above gradually inclosed in calcareous matter, and eventually covered up under a sheet of stalagmite. Now and again the caves were occupied for shorter or longer periods by man—his presence being still evidenced by his implements and weapons, by charred and split bones, &c., and occasionally by portions of his own skeleton—and these relics, in like manner, subsequently became sealed up in a more or less thick accumulation of stalagmite. Some of these bone-caves contain the record of many physical changes. Thus, we have evidence to show that after having been the haunt of wild beasts or the abode of man for some indefinite but often prolonged period, the cave again gave passage to a flow of water, and deposits of loam, clay, or gravel, &c. were laid down upon the stalagmitic pavement and bone-breccia. Or, as in some cases, the stalagmite, together with bones covered by and inclosed within it, was broken up and partially or wholly removed. Then, at a subsequent date the stream once more deserted its channel, while carnivores or man again returned, and newer heaps of bones and stalagmites accumulated. Commingled with these stalagmites of the bone-caves there is almost always more or less of a reddish earth or clay, which is the insoluble residue of the limestone from the dissolution of which the stalactites and stalagmites are formed. Some of the more remarkable bone-caves which have yielded testimony as to the contemporaneity of man with extinct mammals, are Kent's Cave (q.v.) and Brixham Cave in England, the caves in the valley of the Lesse in Belgium, the caves of Perigord and the Pyrenees in France, and the Kesslerloch near Thüdingen in Switzerland. Bone-caves containing the remains of post-tertiary mammals are rare in North America; those of Brazil have many bones of large rodents and edentates. For caves at Wick, in Scotland, still occupied by tinkers, see Sir Arthur Mitchell, *The Past in the Present* (1880). For accounts of special caves, see the *British Association Reports* (for Kent's Cave) and the *Philosophical Transactions* (1822-73). For general descriptions, see Buckland's *Reliquiæ Diluvianæ*, Dupont's *L'Homme pendant les Ages de la Pierre*, Lartet's and Christy's *Reliquiæ Aquitanicæ*, Lubbock's *Prehistoric Times*, Dawkins' *Cave-hunting*, J. Geikie's *Prehistoric Europe*. For further information as to the European cave-dwellers of prehistoric times, see MAN, FLINT IMPLEMENTS, PLEISTOCENE.

ARTIFICIAL CAVES.—The primitive inhabitants of most civilised countries and many primitive tribes at the present day have been troglodytes or cave-dwellers. In many countries where natural caves are either of rare occurrence or do not occur at all, certain rock-exposures have been artificially excavated, and occupied either permanently as dwelling-places or occasionally as retreats in times of danger, while others have been used as cells, hermitages, or burial-places. Such caves are not uncommon in the cliffs of Scottish river ravines, as at Hawthornden near Edinburgh, and in the valley of the Jed, Roxburghshire. Caves of this kind occur usually in rocks that are readily dug into, such as soft sandstone. Now and again,

they have been excavated in conglomerate, as in the case of Holbie Noble's Cave, Roxburghshire. In volcanic regions it is the softer tuffs or ashes that are usually holed, as in the caves of the Canary Islands. There the Guanches have also excavated caves under the lavas, by simply raking out the more or less loose scorise and cinders which so commonly occur in that position. Vast areas in Central China are covered with a coherent loam (of the same character as the *Loess* (q.v.) of the valleys of the Rhine and Danube), in which dug-out dwelling-places are of common occurrence. And a similar deposit, exposed along the bluffs of rivers in the far west of North America, has been utilised by some of the early inhabitants in the same way. In Arizona, parts of Colorado, Nevada, Utah, and south-east California, the rocky precipitous walls of deep cañons are in places riddled with human habitations, so as to look like honeycombs. The strata forming the walls of the cañons have been eroded in different degrees, and horizontal caves larger and smaller have been formed. The cliff dwellings are often adobe or stone structures built on the ledges overhung by projecting rock masses; smaller caves have served as dwellings, and been partially completed by adobe walls. Some of these houses are at a height of 700 feet above the level of the valley, and are with difficulty accessible. They seem to have been made as places of refuge and defence by the same ancient races as left the *pueblos* or stone ruins in the valleys, like those occupied by the Pueblos and Moqui Indians now. Some assume them to have been the ancestors of the present Pueblos; others that they were akin to the Aztecs. See Hayden in Stanford's *North America*; Nadaillac's *Préhistoire America* (Eng. trans. 1885); and the U.S. Survey Reports since 1874.

Hermitages, belonging to all ages, some of very simple, others of a more elaborate construction, have in like manner been excavated in rocks of very different kinds; so that we are presented with every variety of artificial rock-excitation, from simple hollows scraped out of some soft yielding material to the richly ornamented grottoes and temples of Ellora, near Daulatabad, which are cut out in red granite. And so again in the matter of rock-tombs we meet with artificial grottoes of all kinds—from mere holes picked out without much trouble in loess, tuff, sandstone, or other yielding substance, to the great rock-cut sepulchres of Egypt, and the no less famous catacombs of Rome. Many caves have been doubtless partly natural, partly artificial—the cells of the monks of the Thebaid in Egypt, St Serf's cave at Dysart, St Ninian's at Whithorn. For the cave-dwellers known to the ancients, see TROGLODYTES, PETRA. For the Indian cave-temples, see ELEPHANTA, ELLORA.

CAVE-ANIMALS.—Various caverns, both of the Old and New World, are tenanted by animals which are usually more or less blind. From one point of view the eyes have degenerated from disuse and from the absence of the necessary light stimulus; from another point of view they have degenerated because no longer of use, and no longer maintained by that natural selection which through the struggle for existence is supposed by many to be necessary not only for the establishment, but for the maintenance of organs. The fauna of the Mammoth Cave of Kentucky has been most studied, and is catalogued with figures in Putnam and Packard's description of that famous cavern. Leydig has made a special study of the highly developed tactile organs borne by some fishes frequenting German caves. Among the cave-animals may be noticed the amphibian *Proteus* (q.v.) with eyes in an embryonic state; various Blind Fish (q.v.), such as *Amblyopsis* (q.v.), *Typhlichthys*, &c.; hundreds of

blind insects, of which in some cases (*Machærites*) only the females are blind; blind spiders and myriapods; many Crustaceans (*Niphargus puteanus*, *Titanethes albus*, *Crangonyx*, *Asellus sieboldii*, &c.); a few univalves and other forms.

It is noteworthy that the blindness may exist in various degrees, some being totally blind and others possessing rudimentary eyes. It is also to be remembered that not all cave-animals are blind, but forms with well-developed organs of vision also occur. Fish, insects, spiders, myriapods, and crustaceans with well-developed eyes have been recorded from various caves, and the explanation of this persistence of organs in such environment is still to find. See DEGENERATION, ENVIRONMENT, and Semper's *Natural Conditions of Existence as they affect Animal Life* (International Science Series, 1881).

CAVE BEAR, HYÆNA, LION, &c.—(1) *Ursus spelæus*, a fossil bear, like those now living, found very abundantly in the Pleistocene caves of Europe. (2) *Hyæna spelæa*, once abundant in Britain and other parts of Europe, and very closely allied to the *H. crocuta* now found in Africa. (3) *Felis spelæa*, a fossil lion, very like the modern form, abundant in caves of England and Europe generally. The prefix cave obviously refers to the fact that in caves the fossil remains of recent animals are well preserved and abundantly found.

Cave, EDWARD, the founder of the *Gentleman's Magazine*, was born at Newton, Warwickshire, in 1691; received some schooling at Rugby; and after many vicissitudes, became apprentice to a printer. Obtaining money enough to set up a small printing-office, in 1731 he started the *Gentleman's Magazine*, the earliest literary journal of the kind. Samuel Johnson became its parliamentary reporter in 1740; and with his hand in Johnson's, Cave died on 10th January 1754.

Cave, WILLIAM, divine, born at Pickwell, Leicestershire, in 1637, from Oakham school passed to St John's College, Cambridge (1653), and was appointed to the vicarage of Islington (1662), to the rectory of Allhallows the Great, London (1679), and to the vicarage of Isleworth, Middlesex (1690). He died at Windsor, 4th July 1713. Among his twelve works on church history are *Lives of the Apostles*, *Lives of the Fathers*, and *Primitive Christianity*, which once were standard authorities.

Caveat is a formal warning, entered in the books of a court or a public office, that no step shall be taken in a particular matter without notice to the person lodging the caveat, so that he may appear and object. Thus, caveats are frequently entered at the Patent Office to prevent the unopposed granting of letters-patent; or at the Probate Court to prevent the unopposed making up a title to the property of deceased persons; or at the Admiralty Court to prevent the unopposed arrestment of a ship. The term is also used in ecclesiastical practice in England; although a caveat—e.g. against an institution to a particular benefice—has not now the high effect attributed to it by the Canon Law. In Scotland the term is confined to such notices as are placed in the Bill Chamber (the summary department of the Supreme Civil Court) or in the Sheriff Courts to prevent any interdict being granted without notice to the person interested. Such caveats require to be renewed every month.

Cavedoné, GIACOMO, an Italian artist of the Caracci school, born in 1577 at Sassuolo, assisted Guido Reni at Rome, and finally settled in Bologna, where many of his religious pictures are preserved. He died in poverty in 1660.

Cavendish, the surname of the ducal House of Devonshire, a family directly descended from the

chief-justice Sir John Cavendish, who in 1381 was beheaded at Bury St Edmunds by Jack Straw's followers; and from Sir William Cavendish of Cavendish, Suffolk (circa 1505-57), a brother of Wolsey's biographer. His third wife, the celebrated 'Bess of Hardwick,' afterwards Countess of Shrewsbury, brought Chatsworth (q.v.) into the family; and William, their second son, was in 1618 made Earl of Devonshire. His great-grandson, William (1640-1707), was, under the last two Stuarts, a steadfast member of the Whig opposition, Russell's friend to the death, and an active promoter of the Habeas Corpus Act. He succeeded as fourth earl in 1684, and, for his services at the Revolution, was in 1694 raised to be Duke of Devonshire and Marquis of Hartington. His great-grandson, William (1720-64) succeeded as fourth duke in 1755, and was prime-minister from November 1756 to the following May. William, fifth duke (1748-1811), was a bit of a poet; but is less remembered than his beautiful duchess, whom Gainsborough and Reynolds painted. William, sixth duke (1790-1858), was chiefly distinguished by his sumptuous embassy to St Petersburg (1826); and William, seventh duke (born 1808), had inherited the earldom of Burlington in 1834, twenty-four years before he succeeded his cousin in the Devonshire title.

His eldest son, the Right Hon. SPENCER COMPTON CAVENDISH, Marquis of Hartington, was born 23d July 1833, and was educated at Trinity College, Cambridge, graduating B.A. in 1854. He entered parliament in 1857, being first returned for North Lancashire, then in 1869 for the Radnor boroughs, in 1880 for North-east Lancashire, and in 1885 for the Rossendale division of that county. The representative of a great Whig house, he was chosen as early as 1859 to move the vote of want of confidence that overthrew the Derby government, and between 1863 and 1874 held office as a Lord of the Admiralty, Under-secretary for War, War Secretary, Postmaster-general, and, from 1871, Chief-secretary for Ireland. Neither a born statesman nor great orator, he had yet shown an 'infinite capacity for taking pains,' when, in February 1875, on Mr Gladstone's temporary abdication, he was chosen leader of the Liberal opposition. He led it admirably, and in the spring of 1880, on the downfall of the Beaconsfield administration, was invited by the Queen to form a ministry. He rejected the offer, and served under Mr Gladstone, first as Secretary of State for India, and then as War Secretary from 1883 to 1885. But he wholly dissented from Mr Gladstone's scheme of Irish Home Rule; and since 1886, as head of the Liberal Unionists, he has firmly supported Lord Salisbury's Conservative government.

His younger brother, Lord FREDERICK CAVENDISH, was born 30th November 1836, and was also educated at Trinity, taking his B.A. in 1858. He sat in parliament as Liberal member for the northern division of the West Riding of Yorkshire from 1865 till the spring of 1882, when he succeeded Mr Forster as Chief-secretary for Ireland. Between seven and eight o'clock, on the evening of 6th May, having only that morning reached Dublin, he and Mr Burke, an unpopular subordinate, were stabbed to death in the Phoenix Park. Eight months later, twenty 'Irish Invincibles' were tried for the murder, and Carey and two others having turned Queen's evidence, five of the rest were hanged, three sentenced to penal servitude for life, and the remaining nine to various terms of imprisonment. Carey himself disappeared; but in July news came from the Cape that he had been shot dead by an Irishman named O'Donnell on board an emigrant ship. O'Donnell was brought back to London, and hanged.

Cavendish, GEORGE, the biographer of Wolsey, was born about 1500, and became Wolsey's gentleman-usher at least as early as 1527. He remained in close attendance upon his great master till the end (November 28, 1530), after which he retired to his house at Glemsford, in Suffolk, where he lived quietly with his wife, a niece of Sir Thomas More, till the close of his own life in 1561 or 1562. His affection for the great cardinal was most devoted—he had attached himself to his household, in Wolsey's own words, 'abandoning his own country, wife, and children, his own house and family, his rest and quietness, only to serve me.' He never laid aside his loyalty to his memory, but in the quiet meditation of after-years brooded over his fall, and from it learned for himself 'the blessedness of being little.' Thirty years after he wrote his *Life of Cardinal Wolsey*, one of the most interesting short biographies in the English language. Its pensive wisdom and simple sincerity reflect a pleasing picture of the gentle and refined nature of its author, and enable us to see intimately with our own eyes, but with singular clearness, the outlines of one of the grandest figures in our history. The book, written by a devout Catholic, full of regrets for the past, could not well be printed in Elizabeth's reign, but circulated pretty freely in manuscript copies, as many as twelve of which are still extant. It is almost certain that Shakespeare had read it before writing or collaborating in *Henry VIII.*, as all the redeeming features in the picture of the great cardinal, and the lessons of his fall as a solemn homily upon human ambition, are directly due to the tender and loyal touch of Cavendish. The book was first printed imperfect, for party purposes, in 1641. The best edition is that of S. W. Singer (2 vols. 1815), the text of which was reprinted with a good introduction in Professor Henry Morley's 'Universal Library' (1886).

Cavendish, HENRY, natural philosopher, eldest son of Lord Charles Cavendish, and a grandson of the second Duke of Devonshire, was born at Nice, October 10, 1731. From a school at Hackney he passed in 1749 to Peterhouse, Cambridge, but quitted it three years later without a degree; thereafter he devoted the whole of his long life to scientific investigations, a large fortune bequeathed him by an uncle enabling him to follow uninterruptedly his favourite pursuits. A silent, solitary man, he hated so to meet strangers, that he had his library—a magnificent one—in London, four miles from his residence on Clapham Common, so that he might not encounter persons coming to consult it; whilst his female domestics had orders to keep out of his sight, on pain of dismissal. His dinner he ordered daily by a note placed on the hall-table. He died, unmarried, at Clapham, 10th March 1810, leaving more than a million sterling to his relatives. As a philosopher, Cavendish is entitled to the highest rank. To him it may almost be said we owe the foundation of pneumatic chemistry, for prior to his time it had hardly an existence. In 1760 he discovered the extreme levity of inflammable air, now known as hydrogen gas—a discovery which led to balloon experiments and projects for aerial navigation; and later, he ascertained that water resulted from the union of two gases—a discovery which has erroneously been claimed for Watt (q.v.; see also WATER). The famous *Cavendish Experiment* was an ingenious device for estimating the density of the Earth (q.v.). The accuracy and completeness of Cavendish's processes are remarkable. So high an authority as Sir Humphry Davy declared that they 'were all of a finished nature, and though many of them were performed in the very infancy of chemical science, yet their accuracy and their beauty have remained unimpaired.' Cavendish also wrote

on astronomical instruments; and his *Electrical Researches* (1771-81) were edited by Professor Clerk Maxwell (1879). See his Life by G. Wilson, forming vol. i. of the Cavendish Society's Works (1846).

Cavendish, THOMAS, circumnavigator, was born about 1555 at Trimley St Martin, near Ipswich, and, after squandering his patrimony at court, shared in Grenville's expedition to Virginia (1585). On 21st July of the following year he sailed from Plymouth with 122 men and three ships of 40, 60, and 140 tons, and, by Sierra Leone and Brazil, reached the Strait of Magellan, whose passage took seven weeks. During the nine months that he cruised in the Pacific, he burned three Spanish towns and thirteen ships; then, with a rich booty, but only the largest of his three vessels, he returned by way of the Indian Archipelago and the Cape of Good Hope to England, 10th September 1588. Elizabeth knighted him, and he took to his old mode of life, till in August 1591 he sailed on a second expedition, intended to rival the first. It ended in utter disaster, and in 1592 Cavendish died broken-hearted off Ascension.

Cavendish, WILLIAM, Duke of Newcastle, son of Sir Charles Cavendish, and nephew of the first Earl of Devonshire, was born in 1592, and educated at St John's College, Cambridge. His learning and winning address made him a favourite at the court of James I., who in 1610 created him Knight of the Bath, and in 1620 Viscount Mansfield. Charles I., who was splendidly entertained by him at Welbeck and Bolsover, in 1628 created him Earl of Newcastle, and in 1638 appointed him governor to his son, afterwards Charles II. His support of the king during the contest with the parliament was munificent. He contributed £10,000 to the treasury, and raised a troop of 200 knights and gentlemen, who served at their own cost. As general of all the forces north of the Trent, he had power to issue declarations, confer knighthood, coin money, and raise men; and the last part of his commission he executed with great zeal. After the battle of Marston Moor (1644), Cavendish retired to the Continent, where he resided, at times in great poverty, till the Restoration. In 1665 he was created Duke of Newcastle; and he died 25th December 1676. He was author of two works on horsemanship, and of several plays, not of a character to increase any man's reputation for intelligence. See his Life by his second wife (1667; new ed. by C. H. Firth, 1886).—She, MARGARET LUCAS (1624-74), the daughter of an Essex house, where 'all the brothers were valiant, and all the sisters virtuous,' had married him in 1645, and was herself the author of a dozen folio volumes of poems, plays, letters, &c.

Caviare, the salted roes (immature ovaries) of the common sturgeon (*Acipenser sturio*) and other fishes of the same genus (see STURGEON). It is chiefly prepared in Russia, where, as in various other countries, it is a favourite delicacy, and is largely made in the United States; though the phrase 'Caviare to the general,' shows that the taste is an acquired one. The species of sturgeon from the roe of which it is chiefly prepared inhabit the Caspian and Black seas and their tributary rivers. Among them are the Bielaga, or Great Sturgeon (*A. huso*), the Osseter (*A. guldenstädtii*), the Scherg or Sevruga (*A. stellatus*), and the Sterlet (*A. ruthenus*). The caviare made from the roe of the last-named species is esteemed particularly delicious. Astrakhan is a principal seat of the preparation of caviare. The eggs are more or less roughly separated from the connecting tissue, and, after salting, are packed in small barrels, or the roes may be salted in long troughs, and the eggs passed through a sieve into

kegs. More than 400,000 lb. have been prepared in the Caspian fishery in a single year.

Cavité, a decayed seaport of Luzon, one of the Philippines, 12 miles SW. of the capital. Pop. 2500.

Cavour, COUNT CAMILLO BENSO DI, the restorer of Italian unity and nationality, was born at Turin, August 10, 1810. He was descended from one of the ancient noble families of Piedmont, and being the younger son was destined for a military career. At the military school he distinguished himself by his mathematical talent, and at an early age was appointed to a post in the engineers. But as his liberal opinions proved unfavourable to his stay in the army, he left it in 1831. His good sense, however, taught him that the deliverance of Italy could not be accomplished by secret conspiracy and spasmodic revolutionary outbreaks. There was nothing for him therefore but to retire into private life. Here he devoted himself to agriculture, introducing great improvements in the cultivation of the family estates; and his efforts generally to raise the economic condition of Piedmont were thorough and enlightened. But he had a further end in view; he saw that economic improvement must be the basis for a better social and political order. And he widened his knowledge of economic and political questions by foreign travel, especially in France and England. Constitutionalism as established and practised in England was on the whole the form of government he most admired. During a residence in England he made himself intimately acquainted with the political organisation of the country, and also with its industrial institutions; knowledge of which he made good use on his return to his own country.

In this way for sixteen years Cavour energetically laboured as a private gentleman. No opportunity presented itself for any effective influence in politics, and he wisely abstained. It was very different when the spirit of freedom and innovation once more awoke towards the revolutionary period of 1848. In conjunction with Count Cesare Balbo, he in 1847 established a newspaper, *Il Risorgimento*, in which he advocated a representative system, somewhat after the pattern of the English constitution, as opposed alike to absolutism on the one hand, and mob rule on the other. On his suggestion, the king was petitioned for a constitution, which was granted in February 1848. In the Chamber of Deputies, during the stormy period which succeeded Charles Albert's declaration of war against Austria in March, Cavour strenuously opposed the ultra-democrats, and counselled an alliance with England as the surest guarantee for the success of the Italian arms. In the Marquis d'Azeglio's ministry, formed soon after the fatal battle of Novara, Cavour was successively Minister of Agriculture and Commerce, Minister of Marine, and Minister of Finance. In 1852 he was appointed to succeed D'Azeglio as premier. From this time until his resignation in 1859, in consequence of the conclusion of the peace of Villafranca, Cavour was the originator as well as the director of the Sardinian policy. Taking upon himself at different times, in addition to the premiership, the duties of the Ministers of Finance, Commerce, and Agriculture, and latterly of Home and Foreign Affairs, he greatly improved the financial condition of the country, introduced measures of free trade, consolidated constitutionalism, weakened clerical influence, and made Sardinia a power of some account in Europe.

Hitherto the work of Cavour had been to reform Piedmont, and place its affairs on a sound basis. The Crimean war afforded him an opportunity to begin the task of restoring the unity and national

independence of Italy. It was through his advice and influence that Sardinia took part in the war, and as a result of this he managed to bring the Italian question before the Congress of Paris in 1856. In 1858 Cavour had with the Emperor Napoleon a secret meeting, at which the programme for driving Austria out of Italy was drawn up, and during the early part of 1859 there followed a diplomatic contest with Austria, which Cavour conducted with masterly tact and astuteness. The peace of Villafranca, coming after the successful war of 1859, and leaving Austria in possession of Venetia, was a bitter disappointment to Cavour. He resigned his office; yet he had no reason for despair, as the power of Austria in the Italian peninsula was now really broken. On returning to office in 1860 he resumed his great undertaking, but by new methods. Popular feeling in central Italy declared itself in favour of union with the north, and thus Parma, Modena, and Tuscany came under the sway of Victor Emmanuel. It was the part of Cavour to guide opinion towards this end, gaining time for it while he negotiated with the great powers; but he had to purchase the acquiescence of France by the surrender of Nice and Savoy. He secretly encouraged the expedition of Garibaldi, which in 1860 achieved the deliverance of Sicily and southern Italy. When a Sardinian army marched southwards and on the plains of Campania met the volunteers of Garibaldi, the unity of Italy was already an accomplished fact. In 1861 an Italian parliament was summoned, and Victor Emmanuel was declared king of Italy. For the completion of Italian unity only Rome and Venetia were wanting; with a little patience they too could be won.

Thus had Cavour achieved the task of his life. But it had not been accomplished without a fearful strain on his health. He had to manage the Sardinian parliament, to meet the artifices, protests, and reproaches of many of the great powers, to prevent revolutionary parties from upsetting the practical mission on which he was engaged, and to direct a great popular and national movement towards a reasonable and attainable goal by methods involving the minimum of delay and violence. For the real power of Sardinia was comparatively limited, and a false step might have been serious. The constant strain was too much for him, and he died June 6, 1861, only a few months after the unity of Italy had been proclaimed. The last words he was heard to utter were those so familiar as expressing an important feature of his policy: 'Brothers, brothers, the free church in the free state.' Cavour is admitted to be the *beau idéal* of a practical and constructive statesman, who, aiming at just and reasonable ends, seeks to achieve them by effectual and legitimate methods. He made a reformed Piedmont the basis for attaining the unity and regeneration of Italy. The ambition of Napoleon, the military gallantry of the king, the enthusiasm of Garibaldi, were all made to co-operate towards his plan for satisfying the national aspirations of Italy under a lasting constitutional rule. Through his early death much of the work necessary for a sound and healthy national life was left unfinished, yet the subsequent history of Italy proves that Cavour had built on a solid foundation. He deserves a place among the greatest statesmen of modern times.

The title is taken from the small Piedmontese town of Cavour, 28 miles SW. of Turin. See De la Rive, *Le Comte de Cavour, Récits et Souvenirs* (Paris, 1863; Eng. trans. of same date); Bianchi, *La Politique de Cavour* (Turin, 1885); his *Lettere*, edited by Chiala (6 vols. 1883-87); also the biographies of him by Massari (Turin, 1873) and Mazade (Paris, 1877; Eng. trans. of same date).

Cavy (*Cavia*), a genus of Rodents, best known by the domesticated species (*Cavia cobaya*), the common Guinea-pig (q.v.).

Cawdor, a village in Nairnshire, 5½ miles SW. of Nairn. Cawdor Castle, near by, the seat of the Earl of Cawdor, was founded in 1454, but is one of the three places which tradition has assigned as the scene of King Duncan's murder by Macbeth in 1040. A series of papers from the charter-room at Cawdor was edited by Cosmo Innes under the title of *The Book of the Thanes of Cawdor* (1859). See CAMPBELL.

Cawk, a popular name for a massive variety of the mineral called Heavy Spar or Sulphate of Baryta. See BARYTA.

Cawnpore (*Kanhpur*), a city of the North-western Provinces, on the right bank of the Ganges, 42 miles SW. of Lucknow, 266 SE. of Delhi, and 628 NW. of Calcutta. The river in front, varying, according to the season, from 500 yards in width to more than a mile, presents a large and motley assemblage of steam-vessels and native craft; the principal landing-place is the beautiful Sarsiya *ghât*. Cawnpore, at least as a place of note, is of recent origin, being indebted for its growth, besides its commercial facilities, partly to military and political considerations. In 1777, being then an appendage of Oudh, it was assigned by the nawab as the station of a subsidiary force; and in 1801 it became, in name as well as in fact, British property. In 1881 its cantonments, having accommodation for 7000 troops, contained a population of 31,283, and the city of 120,161, giving a total of 151,444, of whom 113,354 were Hindus, and 3194 Christians. At the outbreak of the mutiny in May 1857, Cawnpore contained about 1000 Europeans, 560 of whom were women and children. The hasty, ill-chosen entrenchments into which they had thrown themselves, were speedily invested by overwhelming numbers of the mutineers, led on by the infamous Nana Sahib. For three weeks the few defenders held gallantly out; but at last they surrendered on promise of a safe-conduct to Allahabad. The sepoys accompanied them to the banks of the Ganges, and scarcely were they embarked on the boats, when a murderous fire was opened upon them, and only four men escaped. The women and children, 125 in number, were reserved for a crueller fate, and were carried back to Cawnpore. Hearing that Havelock was within two days' march of the place, Nana Sahib advanced to meet him. He was driven back, and, smarting under defeat, returned to Cawnpore, and gave orders for the instant massacre of his helpless prisoners, who, dead and dying, were cast into a well. Havelock and his small army arrived on 16th July, only to find to their unutterable horror that they came too late to rescue the women and children. A memorial church, a Romanesque red-brick building, now marks the site of General Wheeler's entrenchment; whilst the scene of the massacre is occupied by the memorial gardens. Over the well itself a mound has been raised, its summit crowned by an octagonal Gothic inclosure, with Marochetti's white marble angel in the centre. But Sir George Trevelyan's *Cawnpore* (1865) is the best memorial of the tragedy.—The district of Cawnpore has an area of 2370 sq. m., and a population (1881) of 1,181,396. It is an alluvial plain of great fertility. The vine is cultivated, and indigo grows wild. Besides its two mighty rivers, the Ganges and Jumna, and their navigable tributaries, the Ganges Canal traverses the country for 60 miles, and there is ample communication by rail.

Caxias, (1) a town of Brazil, in the province of Maranhão, on the navigable Itapicurn, 190 miles from its mouth, with an active trade in cotton.

Pop. 10,000.—(2) An Italian agricultural colony in the Brazilian province of Rio Grande do Sul, founded in 1875. Pop. (1884) 13,680.

Caxton, WILLIAM, the first English printer, was born in the Weald of Kent about 1422. He was apprenticed in 1438 to Robert Large, a wealthy London mercer, who was Lord Mayor in 1439–40. On his master's death in 1441, he went to Bruges; he prospered in business, and became in 1462 governor of a chartered association of English merchants in the Low Countries. In 1471 he abandoned commerce and attached himself to the household of Margaret, Duchess of Burgundy, the sister of Edward IV.; and apparently towards the end of 1476 he set up his wooden printing-press at the sign of the Red Pale in the Almonry at Westminster. The art of printing he had acquired during his sojourn in Bruges, doubtless from Colard Mansion, a well-known printer of that city; and in 1474 he put through the press at Bruges the first book printed in the English tongue, the *Recuyell of the Histories of Troye*, a translation of Raoul Lefevre's work. The *Game and Playe of the Chesse* was another of Caxton's earliest publications; but the *Dictes and Sayings of the Philosophers*, published in 1477, is the first book which can with certainty be maintained to have been printed in England. All the eight founts of type from which Caxton printed may be called Black Letter. Of the ninety-nine known distinct productions of his press, no less than thirty-eight survive in unique copies or in fragments only. His books have no title-pages, although many have prologues and colophons. Some have no points at all; others the full-stop and colon alone. The semicolon never occurs; the comma is usually marked by short (,) or by long (,) lines. The pages are not numbered and have no catchwords. (For Caxton's imprint, see article BOOK.) Caxton enjoyed the patronage and friendship of some of the chief men of his time. He was diligent in the exercise of his craft or in translation till within a few hours of his death, which seems to have happened about the close of the year 1491. Gibbon denounces Caxton's choice of books, and complains that 'the world is not indebted to England for one first edition of a classic author; but it should be remembered that Caxton had to make his printing business pay, and that he could therefore supply only books for which there was a demand. Nor can it be said that a printer had no regard for pure literature who produced editions of Chaucer, Lydgate, Gower, Sir Thomas Malory's *King Arthur*, and translations of Cicero's *De Senectute* and *De Amicitia*. Caxton's industry was marvellous. He was an accomplished linguist, and the translations which he executed himself fill more than 4500 printed pages, while the total produce of his press, exclusive of the books printed at Bruges, reaches to above 18,000, nearly all of folio size. At the Osterley Park sale in 1885, no less than ten Caxtons were sold; one of them, the *Chesse*, bringing £1950. In 1877 the printer and his work were fittingly commemorated by a typographical exhibition in London. See *The Old Printer and the New Press*, by Charles Knight (1854); *Life and Typography of William Caxton* (1861–63), by W. Blades; and the *Biography and Typography of Caxton* (1877; 2d. ed. 1882), by the same author.

Cayenne, a fortified seaport, capital of French Guiana, on an island at the mouth of a river of the same name. A new town is connected with the older portion by the Place d'Armes, bordered with orange-trees. The harbour is the best on the coast, but insecure and shallow. Cayenne, though it is the entrepôt of all the trade of the colony, is chiefly known as a great French penal settlement (since 1852). The climate is extremely unwholesome for

Europeans, large numbers of the convicts having been carried off by various malignant fevers. The French took possession of the island in 1604, and again, after it had been held by the English and Dutch, in 1677. The name of the capital is sometimes used for the whole of French Guiana (q.v.). Pop. about 10,000.

Cayenne Cherry. See EUGENIA.

Cayenne Pepper consists of the powder of the dried pods, and more especially of the dried seeds of species of *Capsicum* (q.v.).

Cayes, or AUX CAYES, a seaport of Hayti, on the south-west coast, 95 miles WSW. of Port-au-Prince. Pop. 8000.

Cayley, ARTHUR, mathematician, was born at Richmond, Surrey, in 1821. He was educated at King's College, London, and Trinity College, Cambridge, and graduated as senior wrangler and first Smith's prizeman in 1842. He was called to the bar at Lincoln's Inn in 1849, and established a practice as a conveyancer. In 1863 he was elected first Sadlerian Professor of pure Mathematics at Cambridge, and in 1875 to a fellowship of Trinity College. He has received honorary degrees from Oxford, Dublin, and Leyden. He was president of the Royal Astronomical Society (1872–73), and of the British Association at its Southport meeting in 1883, where his address on the ultimate possibilities of mathematics attracted much attention. In 1882 he gave a course of mathematical lectures at the Johns Hopkins University, Baltimore, and in the same year received the Copley medal of the Royal Society. His chief book is an *Elementary Treatise on Elliptic Functions* (1876); a ten volume edition of his *Mathematical Papers* was begun in 1889.

Caylus, ANNE CLAUDE PHILIPPE DE TUBIERES, COMTE DE, archaeologist, was born in Paris in 1692. After serving in the Spanish War of Succession, he travelled in Greece and the East, returning to Paris in 1717 to devote himself to the study of antiquities, and the promotion of the fine arts. If his industry sometimes outran his intelligence, it is still true that he did vast service to archaeology. He died at Paris in 1765. His chief work is his *Recueil d'Antiquités égyptiennes, étrusques, grecques, romaines, et gauloises* (7 vols. 1752–67). His copperplate engravings have had a longer life than his stories of Eastern life.

Cayman, a local name loosely applied to various species of alligator—e.g. to *Alligator mississippiensis*, the single species of the United States, or more frequently to other species found in tropical or subtropical America. The name has also been used, to all appearance unnecessarily, as the scientific title of a genus, and as such has been most frequently applied to *A. palpebrosus* and *A. trigonatus*. It seems more reasonable to regard all the alligators as within the limits of a single genus. See ALLIGATOR.

Caymans, three fertile coral islands of the Caribbean Sea, 165 miles NW. of Jamaica, of which they form a dependency. Discovered by Columbus, they were by him called Tortugas, from the abundance of turtle, still the staple production of the group. Area, 225 sq. m.; pop. 2400, 2000 inhabiting the largest island, Grand Cayman.

Cazalla de la Sierra, a town of the Spanish province of Seville, 38 miles ENE. of Seville city, on the southern slope of the Sierra Morena, with important mines, and a trade in olives and wine. Pop. 8322.

Cazem'bé, the title of an African prince, whose territory, also called Cazembé, extends between the Moero and Bangweilo lakes, west of 30° E. long. The people are industrious and skilful husbandmen and smiths, and carry on a brisk trade

in slaves, ivory, and copper, with the Portuguese settlements on the Upper Zambesi. It was in the Cazembé's territory that Livingstone died in 1873.

Cazorla, a town of Andalusia, Spain, 40 miles ENE. of Jaén. Pop. 6651.

Ceanothus. See RED ROOT.

Ceará, a province of Brazil, on the north coast, with an area of 40,240 sq. m., and (1885) 722,000 inhabitants. The interior presents a succession of wooded hills and wide plateaus; cattle-raising is an important industry; cotton, coffee, and sugar are largely grown; and iron and gold are found. The capital, Ceará, had formerly only an open roadstead, but in 1888 extensive harbour improvements, with breakwater and viaduct, were nearing completion. It is the terminus of a railway to Baturité (90 miles), and has a large trade. Pop. 35,000.

Cebadilla. See SABADILLA.

Ce'bes, a Theban, disciple and friend of Socrates, and reputed author of the *Pinax*, or 'votive tablet,' a philosophical dialogue, representing allegorically the temptations of this life, and teaching that True Learning can alone make for happiness. In spite of its pure Attic, and its truly Socratic tendency, modern criticism now assigns the work to the 2d century A.D. It was extremely popular in the middle ages, a sort of 'Pilgrim's Progress' indeed; and was translated into all the languages of Europe, as well as Arabic, which latter version, made possibly in the 9th century, is our sole record of the close of the dialogue. See Jerran's *Cebetis Tabula* (Oxf. Clar. Press, 1878).

Cebu, or ZEBU, is one of the Philippine Islands (q.v.), the seventh in respect of area.

Cebus (Gr. 'an ape' or 'monkey'), a genus of South American monkeys, characterised by a round head and short muzzle, a facial angle of about 60°, long thumbs, and a long prehensile tail entirely covered with hair. The body is covered with short, thick hair. Their voice is soft and pitiful. The species are numerous, all of very lively disposition and gregarious arboreal habits, living in trees. They feed chiefly on fruits, but also on insects, worms, and molluscs. Various species are often seen in zoological gardens and menageries. They are included under the popular designation Sapa-jou in its wider sense, and some of them are the monkeys to which this name is sometimes more strictly appropriated. The names Sajou and Sai or Cai are also given to some of them, and some are called Capuchin (q.v.) Monkeys. One of the most common species in Guiana is the Weeper Monkey, or Weeper Sapa-jou (*C. apella*). Some of the species are adorned with beards. The term Cebidae is often used as a family designation for all the broad-nosed New-World Monkeys (Platyrrhini) with prehensile tails, in contrast to the Pitheciidae, in which the tail is not so adapted. In this family are included the Howling Monkeys (Mycetes), the Spider Monkeys (Ateles), and other genera. See MONKEYS.

Cecidomyia (Gr. *kekidion*, 'a gall-nut,' and *myia*, 'a fly' or 'gnat'), a genus of dipterous (two-winged) insects in the Tipularia (gnat and mosquito) division. They have beautiful, delicate, downy wings, which have three nervures, and are horizontal when at rest; antennæ as long as the body, with bead-like joints, and whorls of hairs at the joints; long legs, and the first joint of the tarsi very short. The species are numerous; nearly thirty in Britain, and sixty in Europe. All are of small size, but some of them are very important on account of the ravages which their minute maggots effect in grain-crops. *C. cerealis*, sometimes called the Barley Midge, a brownish-red fly with silvery

wings, of which the maggot is vermilion coloured, is often very destructive to crops of barley and spelt in Germany. The little maggots live in families between the stalk and the sheath of the leaf, abstracting the juice of the plant.—The Wheat-fly (q.v.) and the Hessian Fly (q.v.) belong to this genus. Some of the species of *Cecidomyia* deposit their eggs on the young buds of trees, which the larvæ transform into galls.

While forms like the Hessian fly are of great economic importance, another *Cecidomyia* is, on account of its extraordinary mode of reproduction, of great scientific interest. According to Wagner, the female lays her eggs under tree-bark or the like; these develop in winter into larvæ. The larvæ, still immature, become reproductive and parthenogenetic. The ovaries rupture, the eggs fall into the body-cavity, where the stimulus of fertilisation is somehow replaced, for the ova develop into larvæ. These eat their parent larva, and after finishing the viscera, leave the empty skin. The nemesis of reproduction overtakes them also, for within them again, though likewise only larvæ, a fresh batch of larvæ develops in similar fashion. After several generations of this immature and fatal reproduction, the final set of larvæ metamorphose in summer into sexual winged insects. See REPRODUCTION.

Cecil. See BURGHEY and SALISBURY.

Cecilia, ST, the patroness of music, especially church music, is said to have suffered martyrdom in 230 A.D. Her heathen parents belonged to a noble Roman family, and betrothed their daughter, already a secret convert to Christianity, to a heathen youth named Valerian, who also was soon converted, and ere long suffered martyrdom together with his brother Tiberius. Cecilia, when commanded to sacrifice to idols, firmly refused, and was condemned to death. She was first thrown into a boiling bath, from which she emerged unhurt; next the executioner struck three blows upon her neck with a sword, then fled in horror. Three days later his victim died of her wounds, and received the martyr's crown. She was buried by Pope Urban in the catacombs of Callistus. As early as the 5th century, there is mention of a church dedicated to St Cecilia at Rome; and in 821, by order of the Pope Paschal, her bones were deposited there. St Cecilia is regarded as the inventor of the organ, and in the Roman Catholic Church her festival-day, November 22, is celebrated with splendid music. Some of our greatest poets, as Chaucer, Dryden, and Pope, have laid poetic tributes on the shrine of St Cecilia—the greatest is Dryden's splendid ode. The most famous paintings of St Cecilia are those of Raphael at Bologna, Carlo Dolce in the Dresden Gallery, Domenichino in the Louvre, and Rubens in the Berlin Museum.—Another St Cecilia was born in Africa, and suffered martyrdom by starvation under Diocletian. Her festival falls on the 11th of February.

Cecropia, a genus of Artocarpacæ. *C. peltata*, the Trumpet-tree of the West Indies and South America, has a hollow stem and branches, exhibiting merely membranous partitions at the nodes. The branches, these partitions being removed, are made into water-pipes and wind-instruments. The wood is very light, and is used to make floats for nets, and by the Indians in kindling fires by friction against a harder piece of wood. The bast yields a cordage fibre, and the outer bark is astringent, the fruit resembles a raspberry, the buds furnish a potherb, while the juice hardens into caoutchouc. The leaves and fruit are largely consumed by sloths. The hollow stem is largely inhabited by ants.

Cecrops, a Pelasgic hero, the first king of Attica, sometimes represented as half man and half dragon. He divided Attica into twelve communities, founded Athens, the citadel of which, at first called Cecropia, commemorated his name, instituted marriage and the worship of the gods, and introduced agriculture, navigation, and commerce. Late writers explained Cecrops as the leader of a colony from Sais in Egypt.

Cedar, or CEDAR OF LEBANON, a tree much celebrated from the most ancient times for its beauty, its magnificence, and its longevity, as well as for the excellence and durability of its timber. It is often mentioned in Scripture; it supplied the woodwork of Solomon's temple; and in the poetry of the Old Testament it is a frequent emblem of prosperity, strength, and stability. It belongs to the natural order Conifere, and is the *Pinus Cedrus* of the older botanists; but is now ranked in the genus *Cedrus* under the name of *C. Libani*, in reference to its best-known habitat, Mount Lebanon. It is found, however, on other mountains of Syria and Asia Minor, and also in Cyprus.

Of the celebrated Cedars of Lebanon only a few now remain. Situated at the head of the Kedisha Valley at 6314 feet elevation, they consist of a grove of trees, 377 in number in 1875, five only being of

liform appearance in graduated stages from base to summit of the tree. The leaves are about an inch long, arranged in clusters, persistent for about two years, at first bright green, but changing with age to a deeper tint, with a glaucous hue, which in some individual trees increases to an almost silvery

Branch of Cedar of Lebanon.

Cedars of Lebanon.

gigantic size, measuring 30 feet round. In age they may vary from 50 or 80 to 800 or 1000 years; but as they have long ceased to add regularly yearly concentric rings of wood to their trunks, there are no reliable data by which to estimate the age of the few patriarchal cedars that yet remain on the Lebanon. Arabs of all creeds have a traditional veneration for these trees; and Maronites, Greeks, and Armenians annually celebrate mass on a homely altar of stone at their feet.

The general aspect of the cedar is distinct and majestic in fully developed trees. The trunk is massive, but attains only a moderate height—50 to 80 feet—much branched; the branches assume the proportions of timber, are horizontal, and spreading usually so as to exceed the total height. They are arranged in apparent whorls, or stages, and the branchlets springing from them in a flat fan-like fashion in great profusion and density impart a tabu-

whiteness that gives to them a strikingly venerable aspect. The cones are erect on the upper sides of the branches, from 3 to 5 inches long and 2 to 2½ inches broad, blunt at both ends. They require two years to reach maturity, and do not, as in the case of other allied conifers, drop from the branches, but when ripe the scales only along with the seeds drop to the ground, and leave the axis of the cone attached to the branch.

The timber of the Lebanon cedar enjoyed a high reputation for durability in ancient times, which, however, is hardly supported by modern experience. The wood of trees that have been grown in Britain and other parts of Europe has proved light, soft, brittle, liable to warp, and far from durable, probably owing to the immaturity of these comparatively young, though well-developed, samples, and also perhaps to climatic influence. The superior quality of the timber of the Lebanon trees is attested by Sir Joseph Hooker, who visited the famous cedar grove in 1860.

The secretions of the cedar of Lebanon have long been celebrated for remarkable properties. The whitish resin (*Cedria*) which it exudes, it is said the Egyptians used in embalming their dead. Ancient writings were kept in cabinets or boxes of cedar-wood, but it would appear to be rather dangerous to commit modern printed documents to such repositories. Mr Smee, in *My Garden*, says: 'The wood of the cedar contains a volatile essential oil, which has the curious property of unsettling printers' ink and making it run. Some years ago a Bank of England note was offered to the cashier with its printing disturbed. Inquiry was set on foot, and it was traced to several individuals, who satisfactorily explained its custody and possession. It was then brought to me, when I suggested that the detectives should inquire whether it had been kept in a cedar box; it was then discovered that the last possessor had kept it in a new cedar box which she had recently bought, and thus the mystery was solved.' In very ancient times, cedar-oil, a kind of turpentine, was prepared from the wood, and was spread on books in order to their better preservation. The branches of the cedar, like those of the larch in warm countries, exude a sweet substance, which is known by the name of Cedar Manna.

The botanist Belon brought a Lebanon cedar with him to France in 1549: when it was intro-

duced into Britain is not exactly known. The distinction of introducing it is ascribed with most evidence of accuracy to Evelyn, who in his *Sylva* (published 1664) mentions having 'received cones and seeds from the mountains of Libanus,' while describing the beauties of the tree and speaking of its probable adaptability to the English climate. Aiton in *Hortus Kewensis* makes 1683 the date of planting the celebrated Chelsea cedars, which are assumed by some to have been the first trees planted in England. There are many fine specimens of the Lebanon cedar in different parts of Britain, notably at Sion House, Goodwood, and Enfield in England, and at Hopetoun, Dalkeith, and Beaufort in Scotland.

The Deodar, or Himalayan Cedar (*Cedrus Deodara*), a tree held in great veneration by the Hindus, and of which the name is properly *Devadara* ('divine tree'), is common in the Himalaya mountains at elevations of 7000 to 12,000 feet, forming magnificent forests, and attaining a great size, a height sometimes of 150 feet, with a trunk 30 feet or more in circumference, an ample head, and spreading branches. It and the cedar of Algiers (*C. Atlantica* or *Africana*), found in the mountainous regions of the north of Africa, are but sub-species or varieties of the *Cedrus Libani*. The wood of the deodar is resinous, fragrant, compact, and very durable. It is susceptible of a high polish, and in its polished state has been compared to brown agate. Owing to the abundance of resin, laths of it burn like candles. Its turpentine is very fluid, and although coarse, is much used in India for medical purposes; and tar and pitch are obtained from the trunk. The deodar has now become very common as an ornamental tree in Britain, although few specimens have yet attained a very considerable size.—The name cedar is often given to other coniferous trees besides the true cedars. Thus, the Siberian Stone Pine, or Cembra Pine, is called the Siberian Cedar (see PINE), and a species of fir (*Abies religiosa*) is the Red Cedar of California (see FIR). A species of Cypress (q.v.) is known as White Cedar, and another as the Cedar of Goa. Several of the trees which bear the name cedar are species of Juniper (q.v.), among which are the Virginian Cedar, or Red Cedar of North America, and the Bermuda Cedar—which yield the cedar-wood used for pencils—the Spanish Cedar of the south of Europe, &c. The name cedar is even given to trees which have no resemblance to the true cedars except in the resinous quality of the wood; thus the Cedar-wood of Guiana is produced by *Iceia altissima*, a tree of the natural order Amyridaceæ (q.v.); the cedar of the West Indies (see next article) belongs to the natural order Cedrelaceæ; and the name Bastard Cedar is given in India to a tree of the natural order Byttneriaceæ (q.v.).

Cedar, BARBADOES, is strictly speaking *Juniperus barbadensis*; but a more important tree is that called Bastard Barbadoes Cedar (*Cedrela odorata*), a tree of the order Cedrelaceæ (q.v.). Its wood has an agreeable fragrance, and being soft and light, it is used for canoes and for shingles. Havannah cigar-boxes are very generally made of it, and in France it is used in making black-lead pencils.

Cedar-bergen, a mountain-range in Cape Colony, stretches north and south on the east side of Olifant River Valley, in Clanwilliam division, and has plantations of Cape cedar (*Widdringtonia juniperoides*), which are now, however, being fast destroyed. This is the only locality where this species is found. Sneeuwkop (6335 feet) is the highest point of the range.

Cedar Bird. See WAXWING.

Cedar Creek is a river of Virginia, U.S., which gives name to a battle fought 19th October 1862, when the Federals under Sheridan defeated the Confederates under Early.

Cedar Rapids, a town of Linn county, Iowa, on the Red Cedar River, 79 miles SW. of Dubuque. It is an important railway centre, and has several large flour-mills, carriage and machine works, and breweries. Pop. (1860) 1830; (1880) 10,104.

• **Cedilla** (Sp., Fr. *cedille*, It. *zediglia*; from *zeta*, the Greek name for *z*, because it has taken the place of *z* in such words as *leccon*, mod. *leçon*, a mark placed under the letter *c* (*ç*), especially in French, where it is desired to give *c* the sound of *s* before the vowels *a*, *o*, *u*).

Cedrate. See CITRON.

Cedrelaceæ, a sub-order of Meliaceæ (q.v.), all tropical or subtropical trees or shrubs, with pinnate leaves, mostly valuable for their timber—e.g. mahogany, satin-wood, toon, Barbadoes cedar, the yellow-wood of New South Wales, &c. The bark of some species are febrifugal. See MAHOGANY, CEDAR (BARBADOES), &c.

Cefalu, a town of Sicily, on the north coast, 40 miles ESE. of Palermo. It is situated at the foot of a lofty promontory (1235 feet), with old Greek and Saracenic remains. It has a cathedral, a port, and 12,714 inhabitants, chiefly engaged in marble-quarrying and fishing.

Ceglie, a town in Southern Italy, 21 miles NE. of Taranto. It has a trade in grain, oil, and fruit. Pop. 13,865.

Ceiling (Fr. *ciel*; Lat. *cælum*, 'heaven'). This term seems to have been suggested by the use of arched coverings for churches, and even for rooms, which prevailed in the middle ages, and were frequently painted blue and decorated with stars. Arched ceilings among the Romans were known by the name of *camere*, and were formed by semi-circular beams of wood, at small distances from each other, over which was placed a coating of lath and plaster. But the ceilings most commonly in use amongst the Romans were flat, the beams, as in modern times, having been at first visible, and afterwards covered with planks and plaster. Sometimes hollow spaces were left between the beams, which were frequently covered with gold and ivory, or paintings or 'paterae'—large flowers—such, for instance, as are used in the panels of the vault of the Pantheon. The oldest flat ceiling in existence is believed to be that of Peterborough Cathedral. Like that at St Albans Abbey, it is made of wood. Ceilings of churches in the middle ages were generally painted and gilded in the most brilliant manner; and many existing ceilings still exhibit the traces of early decoration of this kind. In French churches the ceilings are generally vaulted, but in England they are more usually of wood. The older ceilings generally follow the line of the timbers of the roof, which, in the Early English and Decorated, are often arranged so as to give the shape of a barrel vault. In ceilings of this description there seldom are many ribs, often only a single one along the top. In the Perpendicular style, the ceiling often consists of a series of flat surfaces or cants, formed on the timbers of the roof. Though sometimes altogether destitute of ornament, they are more frequently enriched with ribs, dividing them into square panels, with Bosses (q.v.) or flowers at the intersections. Wooden ceilings are sometimes formed in imitation of stone-groining, with ribs and bosses, examples of which will be found at York, Winchester, and Lincoln. In the Elizabethan age ceilings were generally of plaster, but they were ornamented with ribs having bosses or

small pendants at the intersections. It is not unusual for the ceiling immediately over the altar, or the roodloft, to be richly ornamented, whilst the rest is plain. See ROOF.

Celakovsky, (1) FRANZ LADISLAUS, Bohemian poet, born in Strakonitz, 7th March 1799, died at Prague, professor of Slav Philosophy, 5th August 1852. His principal works are *Echoes of Russian and Bohemian Folk-songs* (1833-40), and a cycle of love-songs and didactic and political poems (1840). He also translated the works of Herder, Goethe, and Scott.—(2) LADISLAUS, botanist, born in Prague, 29th November 1834, was appointed professor of Botany there in 1880. Besides several monographs on particular genera, he has published a general book on the Bohemian flora (3 parts, 1867-75) and an elucidation of the Darwinian theory.

Celandine is the popular name (and corruption) of *Chelidonium majus*, a perennial papavera-

Celandine (*Chelidonium majus*):
a, a flower.

ceous herb, which, although not uncommon in Britain, is doubtfully indigenous. Its pretty foliage

Lesser Celandine
(*Ranunculus Ficaria*).

Its pretty foliage and umbels of small yellow flowers, which bloom from May to August, might alone attract attention, but its ancient repute among herbalists is due to its yellow milky juice, which is very acrid and poisonous. Externally it was applied to warts and ulcers, and internally administered, it was supposed to be a specific for jaundice, apparently on no better warrant, however, than that drawn from its colour by the 'doctrine of signatures.' Its old English name Swallow-wort, which appears to be almost a translation of the botanical one, seems founded on a supposed association between the beginning and ending of its flowering time and the arrival and departure of the swallows.—It is, however, the LESSER CELANDINE which is more familiar to general readers, at least since Wordsworth devoted no fewer than three poems to its honour. This is *Ranunculus Ficaria*, also known as the common fig-wort or pile-wort, a quite unre-

lated ranunculaceous plant, which grows in abundant patches in fields and coppices, and brightens them in early spring with its plentiful golden flowers. Its tuberous roots and swollen separable buds give it additional botanical interest, while it is also noteworthy that these results of peculiarly vegetative habit are associated with a frequent imperfect maturity of the pollen. See REPRODUCTION.

Celastraceæ. See SPINDLE-TREE.

Celaya, a town in the Mexican state of Guanajuato, on the Rio Laja, about 150 miles by rail NW. of the city of Mexico, has several fine plazas, handsome churches, and manufactures of cotton and woollen cloths and saddlery. Pop. (1877), with district, 28,336. The burning of its bull-ring, on Easter Sunday 1888, caused considerable loss of life.

Celebes (in England usually pronounced *Ce'lebes*), the third largest and the central island of the Eastern Archipelago, from 1° 45' N. to 5° 37' S. lat., and from 118° 49' to 125° 5' E. long.; about 800 miles long by 200 broad; total area estimated at 76,260 sq. m. It is practically a Dutch possession, though there are numerous small native states. In configuration, it consists of a central nucleus whence radiate four long mountainous limbs, respectively E., NE., SE., and S., inclosing the three gulfs of Gorontalo, running in nearly 200 miles, Tolo 150 miles, and Boni about 200 miles. The gulfs, as also the north and west coasts, are studded with islands, rocks and shoals, and larger outlying islands. Of the central nucleus and the two inner limbs little is known. The east end of the eastern peninsula (north end of island), Minahassa district, is subject to earthquakes, and contains 11 volcanoes, some of them active, such as Mount Sapotan (5938 feet), and, farther east, Mount Klabat (6559 feet), which has now, however, long been quiescent, besides numerous hot springs and sulphur lakes. The mountains of the south peninsula, essentially a limestone formation, seldom rise above 2000 feet. In the extreme south, however, are Maros (4225 feet) and Bonthain (9994 feet). The uplands of the south peninsula are well wooded, but its vegetation is much less luxuriant than that of the east peninsula. Between the hills and coast of the south peninsula are extensive grassy plains, affording pasture for large herds of cattle, and for the horses for which the district is famous.

Celebes is rich in lakes, among them, Passo, in the central nucleus, 35 miles by 25 miles, and Tondano, nearly 2000 feet above the sea. There are numerous streams, but Celebes, no part of which is more than 50 miles from the sea, offers no space for the formation of large rivers. The Sadang, rising near lake Passo, flows due south for nearly 120 miles.

Thanks to the elevation of the land and its sea-exposure, Celebes enjoys a comparatively cool and healthy climate. The vegetation includes rice, maize, coffee, sugar, tobacco, indigo, areca, betel, pepper, clove and nutmeg growing wild; the tree yielding macassar oil, oak, teak, cedar, ebony, sandalwood, bamboos; also the *upas*. Minahassa, the most highly cultivated district, 60 by 20 miles, has coffee plantations, producing coffee of a remarkably fine flavour, entirely in the hands of the government, and where alone the 'culture system' has been applied in its integrity since 1822. Many animals, birds, and insects are wholly peculiar to Celebes—a tailless baboon, two kinds of cuscus, the babiroussa, and Sapi-utan, three kinds of starlings, two magpies, &c. Gold is obtained from surface washings, principally in Minahassa and Gorontalo districts; iron in the districts bordering the Gulf

of Tolo. Salt is also abundant. Tin and copper are likewise worked.

In 1883 the pop. of Celebes with adjacent islands was given as 926,132, inclusive of 6949 Chinese and 2110 Europeans, but probably exclusive of the pop. of the two inner peninsulas. The Bugis (see BONI) and Mangkassars of the south peninsula, tall, shapely, and comparatively fair, are the dominant native race, much disposed to trading and seafaring. The 'Alfuros,' a collective name for the other native tribes, are at a very low grade of culture. Celebes was first visited in 1525 by a Portuguese expedition from the Moluccas. In 1607 the Dutch began to trade with Celebes, and now claim the whole island, which they have divided into the residencies of Macassar and Menado, a third division round the north and west of the Gulf of Tolo being included in the residence of the Ternate. The total value of the exports in 1884 was £600,000, of which coffee formed nearly a half; and the imports in the same year, £465,714. The women of Celebes weave the sarang, or national garment, which, together with variegated mats, is largely exported. A 'high-road' skirts the coast of the south peninsula from Mandale, 30 miles N. of Macassar, to Balang-Nifra, on the Gulf of Boni; elsewhere are only ordinary roads and footpaths. The chief town is Macassar, with a sea-frontage of nearly 2½ miles. Menado, the capital of Minahassa district, and seat of a Dutch resident, is described as the prettiest settlement in the whole of the Dutch East Indies, and has a pop. of 2500. See Lahure, *L'île de Célèbes* (Paris, 1879).

Celery (*Apium*), a widely distributed genus of Umbelliferae. The common celery (*A. graveolens*) is found wild in Britain and most parts of Europe, in ditches, brooks, &c., especially near the sea and in saline soils, and is acrid and uneatable. In cultivation, however, abundant nutrition has greatly mollified its properties, and two principal forms have arisen—one in which an abundant development of parenchyma has taken place in the leaf-stalks; the other in which it affects the root—while these again possess their sub-varieties. The former sort is the common celery of British gardens, where the familiar long blanched succulent stalks are produced by transplanting the seedlings into richly manured trenches, which are filled up as the plants grow, and finally raised into ridges over which little more than the tops of the leaves appear; and a supply is thus insured throughout the whole winter. The other form is the turnip-rooted celery, or celeriac, and is now largely cultivated on the Continent. Both forms are eaten uncooked alone, or in salads, or in soups, or as a boiled or stewed vegetable, and are pleasant and wholesome, although when used too freely or frequently they are diuretic and aphrodisiac. Some authorities identify celery, instead of the closely related Parsley (q.v.), as the Apium with which victors in the Isthmian and other games were crowned, and of which the Greeks were also wont to twine their sepulchral garlands.

Celeste, MADAME, dancer, was born in Paris 6th August 1814 (by her own account), more probably three or four years earlier. A pupil at the Conservatoire, she early showed remarkable talent. She made her début in 1827 at New York, and during her residence in America married one Elliott, who died early. At Liverpool in 1830 she played Fenella in *Masaniello*; in 1831-33 she became extremely popular in London. Her second visit to America (1834-37) is said to have brought her £40,000. After her return she took part successively in the management of the Theatre Royal, Liverpool, and the Adelphi and Lyceum in London. Her imperfect English long confined her to non-

speaking parts. She retired from the stage in 1874, and died at Paris, 12th February 1882.

Celestine, a mineral bearing the same relation to Strontia (q.v.) that heavy spar bears to baryta. It is essentially sulphate of strontia, SrSO₄, with occasional admixture of sulphate of baryta, carbonate of lime, oxide of iron, &c., in small proportions. It much resembles heavy spar, but is not quite equal to it in specific gravity; is usually blue, often of a very beautiful indigo-blue; sometimes colourless, more rarely reddish or yellowish. Its crystallisation is rhombic, like that of heavy spar. Most beautiful specimens of crystallised celestine are found in Sicily. Celestine derives its name from its colour. It is the source from which nitrate of strontia, employed in the manufacture of fireworks, is derived.

Celestine was the name of five popes, the first of whom filled St Peter's chair in 422-432 (see POPE). The most notable was the Neapolitan Peter di Morrone, who after a long life of ascetic severities was much against his will elected pope as Celestine V. in 1294, when he was nearly eighty years of age. He resigned his office after five months—'the great refusal,' for making which he is placed by Dante at the entrance of hell. He was imprisoned by his successor, Boniface VIII., and died in 1296. He was founder of the Celestines, and was canonised in 1313.

Celestines, an order of hermits of St Damianus, founded by Peter di Morrone about 1254, and confirmed as a monkish order by Urban IV. in 1264 and by Gregory X. in 1274. They called themselves Celestines when their founder ascended the papal chair. They follow the rule of St Benedict, wear a white garment with black hood and scapulary, and live a purely contemplative life. In the 13th and 14th centuries the order spread rapidly through France, Italy, and Germany, but subsequently decayed, and is now almost extinct. The French Celestines were secularised by order of Pope Pius VI. in 1776-78; so also were the Neapolitan Celestines.

Celibacy (from *celibs*, 'unmarried'), a state opposed to the first and strongest natural law (Gen. i. 28), has from a variety of causes come to be regarded in certain religious systems as a condition of the most sublime self-sacrifice. The perpetual celibacy of the priests of Isis, and the chastity of the vestal virgins, are familiar instances. But nowhere was this sentiment so strongly and widely manifested as among the millions devoted to the religion of Buddha. The theories of oriental philosophers and the natural tendency of mystics did not fail to influence the early Christian churches, and led before long to the doctrine that virginity is a state in itself more excellent and more holy than the married life, and to the discipline which, in the Roman Church at least, imposed celibacy upon all priests and sacred ministers. The Old Testament is remarkably free from any tendency to exalt celibacy above matrimony. But although texts may be quoted on either side, the germ of the doctrine in question may be discovered in the New Testament. St Paul affirms it to be 'good for a man not to touch a woman,' and wishes that all men were celibate like himself (1 Cor. vii. 1, 7). Christ himself speaks mysterious words in commendation of those who 'have made themselves eunuchs for the kingdom of heaven's sake;' and the Lamb is followed on Mount Zion by 144,000 virgins, 'first-fruits unto God and unto the Lamb' (Rev. xiv. 1-5).

The apostolic writings, however, while they suggest the excellence of virginity in general, supply no ground for the law of clerical celibacy. In the first epistle to Timothy, the deacon as well as

the bishop is told he must be the husband of one wife, and rule his household and his children well; and 'forbidding to marry' is reckoned among the 'doctrines of devils.' But a remote sanction for the later discipline has been sought for in the regulations of the Jewish priesthood. The Mosaic law forbade priests to marry divorced women or harlots, and enjoined continence upon all when preparing to offer sacrifice. Jerome argues that the Christian priest should offer sacrifice daily, and should therefore be perpetually continent; and Pope Siricius (385 A.D.) insists that marriage was permitted to the priest of the old law only because the sacerdotal order was then limited to the tribe of Levi, but now that the tribal restriction is removed, the license is abrogated also.

The ecclesiastical legislation on celibacy was developed gradually and unequally in the several parts of the church. In the 2d century it became a pious custom to make vows of chastity, and it was thought becoming in the higher clergy to renounce matrimony; and although there are examples of bishops and priests in the first three centuries living with their wives and begetting children, it has been confidently asserted that no instance can be quoted of a marriage contracted at this period after ordination. The obligations of the marriage contract were, however, considered sacred; and the Apostolic Canons impose the penalty of deposition on bishop, priest, or deacon, who should separate from his wife 'under the pretence of piety.' At the end of the 3d and beginning of the 4th century, marriage after ordination was prohibited by formal legislation. A further and important step was taken in the year 305 by the Spanish council of Elvira, which decreed that sacred ministers who were already married, should live in continence. At the Council of Nicaea an attempt was made to impose this new rule upon the whole church, but it was frustrated by the opposition of a venerable monk, Paphnutius, himself a celibate; and the law to this day has never been accepted in the Eastern Church. In the West, however, a series of synodal enactments and papal decrees established or renewed the more rigorous rule. But in no matter of ecclesiastical discipline must the distinction between theory and practice be more carefully observed. The clergy everywhere resisted the law, and resisted with considerable success. St Patrick, who tells us that his father and grandfather were in holy orders, when laying down rules in one of his Irish synods for the conduct of his clergy, directs that 'their wives should keep their heads covered.' In the province of Milan, indeed, the marriage of priests continued to be perfectly legal. Discipline and usage varied in different countries, but it may be safely said that for many centuries the celibacy of the unclastered clergy was little more than a pious fiction, until Hildebrand, afterwards Gregory VII., by his great influence and vigorous measures, secured a more strict observance of the rule.

From the 12th century (first and second Lateran Councils) a great change took place in ecclesiastical law. The marriage of priests was now declared to be not only sinful but invalid. It became henceforward difficult for any priest to justify his marriage on the plea that the prohibition of such marriage was abrogated by custom, or not binding under supposed exceptional circumstances. The clerical consorts became no longer wives but concubines; and, further, the priest who went through the marriage ceremony was held to commit a far greater crime than if he had contented himself with simple fornication. Yet in spite of all this the law was to a large extent set at defiance. In many parts of Europe it was a common thing for benefices to pass from father to son. Influential bishops obtained letters of legitimation for their

children, and provided for them out of the property of the church. Avaricious princes and prelates made traffic of the concubinage of the lower clergy by levying a species of blackmail, under the name of fines, on the tacit understanding that the *focaria*, or occupant of the priest's hearth, should not be disturbed. At the time of the Council of Trent, the Emperor Charles, in the expectation that some relaxation would be made in the laws on the subject, permitted in 1548, by the arrangement known as the *Interim*, married priests to retain their wives until the council should come to a decision. The Emperor Ferdinand a little later (1562) urged upon the same council the abrogation of celibacy. But the Catholic reaction was too strong, and the council in November 1563 pronounced, 'If any one shall say that clerks constituted in holy orders, or regulars who have solemnly professed chastity, are able to contract matrimony, or that, being contracted, such matrimony is valid . . . let him be anathema.'

It should be observed, however, that in the United Greek Church Rome tolerates a married clergy—i.e. a man already married may be ordained priest, and continue to live with his wife, though continence is imposed upon him at certain times. It is the custom for the young candidate for orders to leave the seminary for a while to get a wife, and then return for ordination. If he should become a widower, he cannot of course marry again, and no married priest can be made a bishop. The bishops are therefore, as a rule, taken from the monasteries.

Since the Council of Trent, the observance of celibacy has been comparatively well maintained. This is especially true of those countries where the Catholic community is mixed with or surrounded by Protestant neighbours, and watched by a vigilant press. Away from the high-roads of civilisation, in Mexico, Brazil, and other parts, concubinage has again become the rule, less openly perhaps, but quite as obstinately as in the middle ages.

The moral loss or gain to the church from her discipline in this matter is a question of controversy which from time to time has been raised within her own communion. But the attention paid by biologists to the hereditary transmission of human faculties and dispositions has recently exhibited the effects of celibacy in a new light. Mr Galton has remarked that the Roman Church has acted as if she 'aimed at selecting the rudest portion of the community to be alone the parent of future generations.' The policy which attracts men and women of gentle natures fitted for deeds of charity, meditation, or study to the unfruitful life of the cloister and the priesthood, appears from this point of view to be 'singularly unwise and suicidal,' tending, as it must, though by imperceptible degrees, to the deterioration of the race. To the enforcing of this discipline in Spain, for example (coupled with the cutting off of independent thinkers by the Inquisition), Mr Galton attributes much of the decadence of the country during the last three centuries. In France, where the most promising lads of the village are successively picked out by the parish priest for the bishop's seminary, the process of elimination must in the long run tell upon the general character of the population. In small Catholic communities, again, where the priestly vocation is held in high esteem by the educated classes, and where mixed marriages are discountenanced, a similar result cannot fail to occur. The controversial literature on the matter is abundant. The most complete treatment of the subject, from the historical point of view, will be found in *Sacerdotal Celibacy in the Christian Church*, by Henry C. Lee (Philadelphia, 1867). See also MONACHISM.

Cell, a unit-mass of living matter, whether rounded off by itself, as in the simplest plants or animals and in the youngest stage of all organisms, or associated with other cells to form a higher unity. The great majority of the Protozoa and Protophyta are single cells, and all other organisms begin where the former leave off. From the double unity resulting from the fusion of two sex-cells the higher plants and animals develop by repeated division, and they may be therefore always resolved into more or less close combinations of variously

Fig. 1.—Dividing Egg-cell (after Gegenbaur).

modified unit-masses. In most cases these individualities of the simplest order are minute, and their separateness is not to be discerned with the unaided eye, but there are many instances among the simplest plants and animals, as well as in the component elements of higher forms, where the unit-masses are relatively giant-cells and quite visible without the use of the microscope. The giant *Amoeba Polonyxa*, the common sun-animalcule *Actinospherium*, the Alga *Botrydium*, and some of the cells (e.g. bast) of plants may be noted as illustrations of cells with considerable dimensions. In the great majority of cases the body of the cell includes a well-defined centre or nucleus; and the definition may therefore be extended in the statement that a cell is a nucleated unit-mass of living matter or protoplasm.

I. History.—In the article **BIOLOGY** it has been pointed out that a more and more penetrating scrutiny alike of structure and of function led naturalists from organs to tissues, and from tissue to cell. Some of the steps in this gradually deepening analysis deserve fuller record.

Discovery of Cells.—In the latter half of the 17th century the simple microscope afforded to Malpighi and Leeuwenhoek, to Hooke and Grew, what was literally a vision of a new world. In applying their rough and simple instruments to the study of the structure of plants and animals they became pioneers in the investigation of the infinitely little. Leeuwenhoek (*Phil. Trans.* 1674) seems to have been the first to observe, what are now so familiar, single-celled organisms. In the 18th century Swammerdam and others continued with much enthusiasm to describe the minute intricacies which their 'new eyes' revealed; Fontana (1784) observed the kernel of the cell—the nucleus—and some of the elements of the tissues; but the foundation of scientific histology was not laid until the appearance in 1801 of the *Anatomie Générale* of Bichat. In this epoch-making work organs were resolved into their component tissues, and their functions were interpreted as the sum-total of the properties of their constituent elements. Such a conclusion was the utmost that could be reached with the appliances then at command.

Early in this century, however, an improvement in the appliances of observation furnished a fulcrum for a new advance. Fraunhofer discovered the principle of achromatic lenses (see **LENS, MICROSCOPE**); these were combined into the compound microscope, and a new era began. 'Fibres' and 'globules,' 'lamina,' 'nuclei,' and even 'cells' were described. In 1831 Robert Brown emphasised the normal presence of the nucleus discovered by Fontana, and made the first important advances in the study of the vegetable cell. Isolated discoveries,

such as that of the nucleolus by Valentin (1836), occurred in rapid succession during those years. Dujardin in 1835 described the sarcode or living matter of the Protozoan Foraminifera and of some other cells, and thus emphasised, as Rösel von Rosenhof had done many years before (1755) in regard to the 'Proteus animalcule' or *Amoeba*, the most important element to be considered in forming a true conception of the cell. The importance of his description, of which he was apparently himself unconscious, had for some time the same fate as that of his predecessor of almost a century before. Observations had in fact to accumulate before any generalisation became possible. The first definite steps towards a co-ordination of results was probably that of Johannes Müller, who in 1835 pointed out the resemblance between the cells of the vertebrate notochord and the elements observed in plants. The cellular nature of the epidermis and the presence of nuclei therein was next ascertained, and similar discoveries were made in regard to several other tissues. Up to 1828 there was in fact a period of research in which cells were observed rather than understood.

Establishment of the Cell-theory.—As early as 1826 Turpin had maintained that plants were formed by an agglomeration of cells. Professor M'Kendrick well points out, what one would of course expect, that for some years before 1838 botanists were beginning generally to recognise the cellular composition and origin of plants. The conclusion known as the 'cell-theory' was doubtless vaguely present in many minds. Its definite statement was still wanting. In 1838, however, Schleiden proved that a nucleated cell is the only original component of a plant embryo, and that the development of all tissues might be referred to such cells. In the following year Schwann published at Berlin his famous *Microscopic Investigations on the Accordance in the Structure and Growth of Plants and Animals* (*Trans. Sydenham Society*, 1847). In this classic work it was shown that all organisms, plants and animals alike, are made up of cells, and spring from cells. In composition and in origin there is unity. The generalisation familiarly known as the cell-theory was thus clearly established, and though now a commonplace and postulate of histology, it may fairly be described in Agassiz's words as 'the greatest discovery in the natural sciences in modern times.' Following up the generalisations of Schwann and Schleiden, came a host of researches by which the essential advance contained in the 'cell-theory' was more and more fully confirmed. Cells were not only observed, their import was recognised.

New Conception of the Cell.—When the cell-theory was established, the general conception of the cell was far from being either accurate or complete. It was usually described as a vesicle closed by a solid membrane, containing a liquid in which float a nucleus and granular bodies. It was also the general opinion that such cells originated within a structureless ground substance. In two ways these notions were speedily corrected. On the one hand as regards the origin of cells, Prevost and Dumas (1824), Martin Barry (1838-9), Reichert (1840), Henle (1841), Kölliker (1846), Remak (1852), showed that in the case of the egg-cell, and in the growth of tissues, each new cell arose by division from a predecessor. This important conclusion was most firmly established by Goodsir in 1845, and Virchow in 1858, who proved that in all cases, normal and pathological alike, cells arose from pre-existing cells, a fact expressed in the axiom *omnis cellula e cellula*. In the second place it gradually became apparent that too much importance had been attached to the cell-wall and too little to the contained substance. Referring details to the

article PROTOPLASM, we may note some of the important steps. Dujardin (1835) described the 'sarcode' of Protozoa and other cells; Purkinje (1839) emphasised the analogy between the 'protoplasm' of the animal embryo and the 'cambium' of plant-cells; Von Mohl (1846) emphasised in the clearest way the importance of the protoplasm in the vegetable cell; Ecker (1849) compared the contractile substance of muscles with that of the amoeba; Donders also referred the contractility from the cell-wall to the contained material; Cohn suspected 'that the 'sarcode' of animal and the 'protoplasm' of plant-cells must be 'in the highest degree analogous substance;' and so throughout another decade did botanists and zoologists unite in laying stress rather on the living matter than on the wall of the cell, and in hinting at the existence of one living substance as the physical basis alike of plants and animals. This view found at length definite expression in 1861, when Max Schultze defined the modern conception of the cell as a unit-mass of nucleated protoplasm. Since then the 'protoplasmic movement' has dominated research, and we think not so much of the cell-containing protoplasm as of the protoplasm which constitutes and gives form to the cell.

II. *Structure of the Cell.*—While it is impossible to isolate the static from the dynamic aspects of the cell, it will be convenient to discuss the two separately, and to consider the cell at rest and dead, apart from the cell active and alive. In other words, the form, structure, or morphology may be studied for literary clearness apart from the functions, life, and physiology.

(a) *General Form.*—The typical and primitive form of the cell is spherical. This is illustrated by many of the simplest plants and animals which live freely, and by young cells such as ova. But the typical form is in many, indeed in most cases, lost; and the forms assumed are as diverse as the internal and external conditions of life. The cell may be irregular and protean, as in Amoebae, white blood-corpuscles, and many young eggs; or squeezed into rectangular shape, as in much of the substance of a leaf; or flattened into thinness, as in the outer lining of the lips; or oval and pointed, as in swiftly moving Infusorians and Bacteria; or much branched, as in multipolar ganglion cells of animals or the latex-containing cells of some plants. The typical spherical and self-contained form is that which would naturally be assumed by a complex coherent substance situated in a medium different from itself. The other forms are responses to internal and external conditions. Under the heading *Cell-cycle* below it will be shown how the relative activity and passivity of the cell naturally expresses itself in such extremes as a long-drawn-out Infusorian and a rounded-off Gregarine, or in a highly nourished ovum and a mobile spermatozoon. Further, cells, like entire animals, often show a tendency to become two-ended, to have poles very different from one another. Just as an animal may have a highly nourished head and a scantily nourished tail, so a cell may become distinctly bipolar in form. In other cases the cell is altogether plastic, expressing every impulse of internal change and every impact of external influence in some modification of form. Or the state of nutrition of the living matter may cause alteration in the adhesion of the substance all over, or in particular places, and thus condition an outflowing, regular or irregular, in given directions. Furthermore, external pressure and limitation of growth may square off the cell into a parallelogram, or restrict it to grow like a bast fibre in length alone and not in breadth. In fact the conditions are most manifold, and the resultant forms likewise.

(b) *General Substance of the Cell.*—The cell is much more than a mass of highly complex chemical substance: it has an organised structure. (1) The protoplasm or living matter in the strictest sense is generally supposed to be an intimate mixture of complex and highly unstable chemical compounds. Inspection under a microscope of such cells as amoebae, white blood-corpuscles, ova, simple algae, or such as are readily seen in thin slices of growing plant-shoots, in root-hairs, and transparent parts, will at once furnish an impression of the general aspect of the substance of the cell. Not all that one sees can of course deserve the name of protoplasm, for apart from definite inclosures like starch-grains and fat-globules, much of the remaining slightly clouded substance is hardly to be strictly called protoplasm, but rather represents steps in the ceaseless making and unmaking which form the fundamental rhythm of life. Keeping the definite inclosures and products for the moment aside, we may briefly notice in general outline what has been with most conclusiveness observed as to the structure of the general cell-substance or 'cytoplasm' as it is now frequently termed. All observers agree that the structure is far removed from the homogeneous, though there is much difference of opinion as to the nature of the heterogeneity. In a large number of cases at least the substance of the cell has been resolved into two distinct portions—the one an intricate network, knotted and interlaced in a manner baffling description; the other a clear substance, filling up the interstices or meshes of the living net. Leydig, Frommann, and Heitzmann have been peculiarly successful in unravelling this knotted structure in animal cells, and much the same has been recorded by Strasburger and Schmitz as observable in some plants. The reticulate structure is certainly more doubtful in regard to vegetable cells, and even in some animal cells what some have described as a network others have deemed only a minutely bubbled emulsion.

But besides the real substance of the cell there are to be seen products of various kinds formed from the living matter. The cell may be packed with starch, or laden with fat, or expanded with mucus; it may contain colouring matter in various forms, as in the familiar chlorophyll bodies of many plant-cells; its structure may include, as in some Protozoa, definitely formed fibrils or yet firmer formations of chitin and the like; and again there are concretions of retained waste and reserve products, sometimes in the form of crystals. Not to be overlooked either is the fine 'dust-cloud' of minute granules which are seen suspended in the clearer matrix, and which apparently represent aggregations of diverse chemical substances formed in the building up and breaking down of the protoplasm. As the outside of any mass is bound to be in different conditions from the inside, it is natural to find the appearance of distinct physical and chemical zones in the cell-substance. Thus in many Protozoa the outer portion, needlessly termed 'ectoplasm,' is often denser and more refractive than the more fluid and internal stratum of the 'endoplasm.' Or this may go further, and we may have a sweated-off limiting cuticle, or a definitely organised wall of cellulose in vegetable cells. The cuticle may be further substantiated with secretions of horny, flinty, limy, and other material. Even within the cell a stratified structure may be frequently observed, and Berthold and others have recently emphasised the existence of such concentric layers, each characterised by its own special set of deposits.

Worthy of notice, too, are the various kinds of bubbles or vacuoles which occur in the cell-substance. These may be simply indefinite spaces,

containing some liquid not protoplasm, and including salts and other substances in solution. In many Protozoa they are 'food-vacuoles,' formed by the

Fig. 2.

A, Embryonic cells from growing point of a root; B, older cells becoming vacuolated. (After Sachs.)

bubbles of water engulfed along with the food-particles, round which the protoplasm, shrinking from contact, often forms a definite contour. In other cases they are more permanent, and represent minute reservoirs of secreted substance, cisterns of by-products in the vital manufacture of the cell. Finally they may be seats of special activity, where, perhaps, under the stimulus of irritant waste-products, the protoplasm exhibits spasmodic contractions and expansions, and forms the so-called 'contractile vacuoles,' which in alternate dilatation and bursting often seem to serve to remove fluid from the living matter to the exterior.

(c) *Nucleus*.—In the great majority of cells a central body of definite composition and structure is present which appears to be essential to the life and reproduction of the unit-mass. In many cases the nucleus is well concealed, but as more skilful staining has revealed its presence in many cells which used to be described as non-nucleated, it is rash to conclude too certainly as to its absence in any particular case. Thus some of the Monera, which were formerly defined as the simplest of simple animal organisms without even a nuclei, have been shown to possess them, and the line of division separating Protozoa into Monera and Endoplastica has therefore been removed. Furthermore, the researches of Gruber have shown that in some of the higher Protozoa (ciliated Infusorians) where the nucleus seems entirely absent, dexteros staining prove its diffused presence in the form of numerous granules which take on the characteristic nuclear dye. Yet in some cases, such as the young spores of some Protozoa, the greatest care has not yet been successful in proving the presence of the nucleus. In contrast with these cases, many cells exist in which the nucleus is represented not by one, but by many bodies—the so-called polynuclear state. A further reserve requires to be made, that it is to a large extent an hypothesis that all such definite central inclosures should be slumped together under the one title of nucleus. It is rather probable that in this, as in other organic structures, we have to do with various degrees of development and definiteness.

In the *form* also of the nucleus numerous modifications occur. In the majority of cases, indeed, it is more or less spherical, but it may be elongated, curved, horseshoe-shaped, necklace-like, and even branched. In the young stages of some ova it is like the entire cell, somewhat plastic, and is pulled in and out in amoeboid movements. In special conditions, furthermore, the nucleus may exhibit peculiar deformations. It is in fact a peculiarly sensitive and all-important part of the cell, suffering with it in degeneration, changing with it in growth and division.

In *position* the nucleus is typically central, where as the presiding genius of the cell it shares and perhaps controls the general protoplasmic life. But it frequently suffers displacement both of a passive

and active nature. In accordance with the growth of the cell it may occupy a position distinctly nearer one of the poles. Accumulations of fat or mucus may push it passively to the side. Or it may actively change, in response to hidden forces of attraction between it and the surrounding protoplasm, in the case of some ova exhibiting a peculiar rotation, or else distinctly shifting its ground from the centre towards the periphery.

Structure.—In many cases, as Leydig especially has shown, the nucleus seems to lie in a nest of its own, in a clear space within the surrounding cell-substance. Nor is it in many cases at least definitely insulated from the surrounding protoplasm, but is moored to the latter by strands which have intimate relations with both. As of the entire cell, so of the nucleus it must be said that in the great majority of cases it is very far from being homogeneous. According to Hertwig, Schleicher, Schmitz, Brass, and others, homogeneous nuclei may indeed occur, but if they do they are rare, and it must always be remembered that the nucleus has its history, and may be less complex at one time than it is at another. To Flemming (1882) above all is due the credit of having elucidated the complexity of the nucleus, and the labyrinthine structure to which he showed the clue, and to which Frommann (1867) had many years previously directed special attention, has been studied and restudied by scores of expert histologists during the last six years (1888). While their results disagree abundantly on minor points, two conclusions stand out clearly—(1) that the nucleus has a structure like that of the general cell, consisting of firmer framework and of more fluid intermediate substance, and (2) that apart from detailed difference there is throughout the world of cells a marvellous unity of structure and process, in the nucleus in repose and in the nucleus in action.

In the nucleus the following parts have to be distinguished: (1) The readily stained firmer threadwork, (2) an intermediate clear substance filling up the interstices, (3) definite and usually globular formations known as nucleoli, (4) various granules, and (5) a limiting membrane or nuclear wall. These may be briefly touched upon in order.

(1) *The Nuclear Framework* (reticulum, trabecular framework, &c.).—A mere statement of the different descriptions given of this important part of the nucleus would carry us far beyond the limits of this article. The most marked difference of opinion is this, that some describe the framework as distinctly of the nature of a network, while others are as emphatic in calling it a much-coiled band. A third party unite both views, and regarding the nucleus as variable, describe a reticulum at one time and a coiled filament at another. Thus, according to Flemming, Pfitzner, Retzius, Leydig, Van Beneden, &c., the nuclear framework is typically a reticulum; according to Strasburger, Balbiani, and Korschelt, a twisted ribbon is the only or most frequent form; according to Brass and Rabl, both types may equally occur. A further complication has been emphasised by Zacharias, Pfitzner, Carnoy, and others—this, namely, that besides the readily stained threadwork noted above (the so-called chromatin), whether this be in the form of a reticulum (Pfitzner) or of a coiled ribbon (Carnoy), there exists another—not readily stained—framework of achromatin. This had indeed been recognised though not insisted on by the first series of investigators. To sum up, it is now generally allowed that the framework or threadwork of the nucleus may exist as a network or as a coil, and that it is in a sense double, consisting of readily stainable *chromatin* on the one hand, and unstainable *achromatin* on the other. It need hardly be added that as there is considerable diversity of

opinion as to whether given nuclei have a netted or coiled framework, there is yet greater variety in the minutest description and figuring. According to Flemming the network is quite disorderly, but Rauber, Leydig, and others have described distinct

Fig. 3.—(After Carnoy) :

- A, Cell and typical nucleus: a, slight membrane; b, radiating protoplasmic network; c, wall of nucleus; d, plasma of nucleus; e, nuclear coil.
 B, Nucleus at rest, showing network.
 C, Nucleus before division, showing coiled filament.

radial structure; according to some the nuclear coil is endless, while others describe it as divided into portions; and when we descend to such subtleties of observation as the intimate structure of the threadwork or the relations between chromatin and achromatin, the diversity is so great that it seems desirable here to leave such minutiae untouched.

(2) *The Intermediate Nuclear Substance.*—Besides the nuclear elements of definite form, whatever that form may precisely be, all investigators describe an intermediate substance of variable consistence, usually semi-liquid, amorphous and structureless, but with fine granules. It is a clear unstainable 'plasma' filling up the chinks, but nothing definite is known as to its composition. (3) *The nucleolus* which lies within the nucleus varies greatly in size and position, and more than one are very generally present. Flemming has defined them as 'portions of the nuclear substance, distinct in structure from network and plasma, definitely limited and smoothed, always rounded in outline, usually suspended in the network, but often independent of it.' But when the minute structure and the relation of nucleoli to nuclear framework are inquired into, or the question of physiological rôle raised, very great diversity of opinion is found to obtain. (4) Bodies different in appearance from nucleoli may occur inside the nucleus, but of these little is known. (5) The wall which bounds the nucleus seems to be a true integral part of the latter, but disappears at the beginning of division.

(d) *The Cell-wall.*—In the older conception of the cell, which was practically that of a closed bag, the wall of the cell figured very prominently. But Nägeli showed (1845) that some vegetable cells were destitute of walls, Leydig (1857) defined the cell in respect to its substance, Schultze and others described naked Protozoa, and the progress of the 'protoplasmic movement' led to the abandonment of the position that the wall was a necessary or important part of the cell. In many cells, indeed, a limiting layer is very clearly present, and a sheath or cyst is especially characteristic of passive cells. Plant-cells are almost always distinguished by the possession of a limiting wall, of definite chemical composition, consisting of what is known as cellulose. An analogous wall occasionally occurs round animal cells. In the latter, however, the membrane is usually a comparatively slight thing, and may arise (1)

from an aggregation of the threads and knots of the framework; (2) as a cuticle or capsule formed from the matrix or ground substance; (3) from a combination of both these elements. Leydig has shown that in a very wide series of animal cells the membrane, such as it is, is penetrated by small but definite pores. It is very important further to remember that both in plants and animals the cells are in a great number of cases connected with one another by intercellular bridges of protoplasm, and are in nowise to be thought of as closed bags. The cell-wall of plants, which, be it again noted, is a definite chemical substance, grows in extent and thickness by an intricate organic process, in the course of which new infinitesimal elements form apparently as intercalations between the old. The growth is in very many cases far from uniform; pits, ridges, and manifold kinds of sculpturing thus appear, and give rise to numerous detailed variations. The formation of new boundaries when a cell divides is a question of much difficulty; but in plant, and apparently in some animal cells, the formation of a 'cellular plate' is one of the last events in the dividing process.

III. *Physiology of the Cell.*—When the entire organism is simply a cell, as in most of the Protozoa and Protophyta, all the vital processes which in higher forms have their seat in special sets of cells, known as tissues and organs, are of course discharged by the unit-mass. Thus a unicellular organism like the Amoeba takes in energy as food in nutrition, works it up into living matter in digestion and assimilation, and expends it again in contraction and locomotion. As in any higher organism the oxygen required for the chemical breaking up of the protoplasmic molecules, the air for the vital flame, is taken in by the absorption known as respiration, and the waste carbonic acid gas is in an essentially similar way got rid of. Further, more solid 'ashes' of the vital combustion are formed in the Amoeba and in other actively living cells, and may pass out in excretion along with the refuse of unusable food-material. The absence of a circulating fluid, of digestive glands, nerves, sense-organs, lungs, kidneys, and the like, does not in any way restrict the vital functions of a unicellular organism. All goes on as usual, only with greater chemical complexity, since all the different processes have but a unit-mass of protoplasm in which they occur. The physiology of independent cells, instead of being very simple, must be very complex, just because structure or differentiation is all but absent. It is, however, possible to express the manifold processes in a comparatively simple way by remembering what Claude Bernard was one of the first clearly to emphasise, that vital processes must be really only twofold—building up and breaking down of living matter. On the one hand the protoplasm or real living matter is being by a series of chemical processes built up or constructed; on the other hand, in activity it is breaking down or being destroyed. The income of food or energy is, at the expense of the cellular organism, gradually raised into more and more complex and unstable compounds, until the genuine most complex and more unstable living matter itself is reached. On the opposite side, with liberation of energy in the form of work, this living matter breaks down into simpler and simpler compounds, until only the work, the waste products, and heat remain as the equivalent of the income of energy or food on the other side of the life-equation. On the one hand there are constructive processes, on the other, destructive; chemical synthesis and chemical dissolution is another expression of the contrast; while the two sets of processes are in more modern

language respectively termed anabolism and katabolism (see PROTOPLASM).

But only a few cells, comparatively speaking, live a free and independent life. The majority are component elements in higher unities. In these the original many-sidedness of function is more or less lost, or at anyrate in abeyance, and that exactly in proportion to their degree of subordination. Even in individual cells there is a tendency, obviously within narrow limits, towards differentiation—that is, to the restriction and specialisation of certain parts for certain functions. But when the cells form elements of a larger whole, the division of labour finds full effect. From position and other conditions the cells cease to be uniform or metaphorically many-sided. Certain sets predominate in contractility, others in irritability, others in secretion, others again in storage, and so on. In such cases one function predominates over the others, which are subordinate or only dormant possibilities. Thus arise muscle-cells, nerve-cells, glandular cells, fat-cells, and the like. Compared with *Amœba*, those cells must have a simpler physiology; they may have gained in complexity of structure, but have lost in manifoldness of function. The aggregation of similar cells, usually with one predominant habit or function, results in the formation of tissues, and the discussion of the different sets may well be referred to the article HISTOLOGY.

One general physiological fact may, however, be referred to which will greatly assist in understanding the life both of independent cells and of those which form the elements of tissues. A survey of the unit-organisms, both among plants and animals, reveals the existence of three well-marked phases. Some cells are emphatically active, equipped with motile lashes (cilia or flagella), and obviously liberal in their expenditure of energy. Others are just the reverse of this, emphatically passive, wrapped up in themselves and without motile processes, obviously economical in their expenditure, conservative of their income. A third set form a mean between these two extremes, are neither encysted like the latter nor lashed like the former, but furnished with the relatively slow-moving processes characteristic of *Amœba*, and living in a *via media* between activity and passivity. These three types may be termed respectively ciliated, encysted, and amœboid, or active, passive, and moderate. That these types generally correspond to the three great divisions of the Protozoa shows that they represent the three main possibilities of cellular life. Now in the very simplest forms all the three phases occur in one life-history; no step has, as it were, been taken in any one of the three directions; the primitive cells are in a state of physiological indifference. What has happened in the

accentuated to the more or less marked subordination of the others. Not that the emphatic adoption of one line of cell-life excludes the others; they may in fact occur as temporary stages, or as pathological deviations.

But while simple observation is sufficient to establish the existence of a cycle of phases in the life of primitive cellular organisms, such as *Protomyxa*, and the existence of three main lines of specialisation among the Protozoa, the importance of this conception of a 'cell-cycle' becomes increased and justified when the facts are considered physiologically. If we start from a simple cell, such as an *Amœba*, it is evident enough, from what has been already said as to the twofold nature of all vital processes, that the principal physiological possibilities are the three phases above indicated. (On the one hand, with preponderance of income over expenditure, of constructive over destructive changes, of anabolism over katabolism, the cell must tend to become larger in size, more weighted with stored material, more sluggish or passive in habit, and more rounded in form. But if the reverse take place, the cell will tend to become less bulky, more active or locomotor in habit, and more elongated

Fig. 5.—*Protomyxa* :

1, encysted; 2, dividing; 3, spores escaping as ciliated bodies, passing into 4, amœboid state; 5, 'plasmodium' forming from fusion of amœboid cells.

in form. The sweated-off cyst of the former, the motile processes of the latter, are expressions of exactly opposite constitutions and conditions. A third physiological possibility remains, that namely of continuing in a position of average equilibrium between income and expenditure, between anabolism and katabolism, in a middle way between the fitful fever of extreme ciliated activity and the sluggish sleep of encysted passivity.

Now if we take these two facts—the existence of a primitive cycle through which cells tend to

Fig. 6.—The Cycle of Cell-life :

a, encysted; b, ciliated; c, amœboid; d, plasmodial.

Fig. 4.—Phases of Cell-life. (After Geddes.)

Development of passive or resting, intermediate (amœboid), and active (motile) states.

higher classes of Protozoa—Infusorians, Greeniids, Rhizopods—is that one phase has been

pass, and the existence of three main physiological possibilities which lie behind the cycle—we are in a better position to understand both the changes exhibited in normal and pathological conditions by individual cells, and the various forms of cells as they occur in the tissues of the higher organisms. Thus lashed cells such as those of the windpipe of mammals, the skin of many lower worms, the inside of a *Hydra*, the male elements of most animals and many lower plants, emphasise one phase in the cycle, and it is not surprising to find that in certain conditions they may sink down into the amœboid type. Or again, the amœboid character of young ova, preceding the more passive and encysted condition of the mature cells, is in view of the 'cell-cycle' a most natural procedure. In many cases artificial stimulus of various kinds has been shown to make cells pass from one phase to another of the primitive life-cycle theoretically possible to all. In the same way the preponderance of cellulose in cells

encysted is a natural character of the passive plants, and the insheathed cells of many animal tissues may be similarly expressed as an exhibition of the same passive phase. But it is enough here to point out the possibility of classifying and interpreting the various cells composing the tissues of higher organisms in terms of an original life-cycle, or deeper still in terms of those twofold protoplasmic possibilities which lie behind all forms and phases whether of cells, tissues, or organisms themselves. This conception of a cell-cycle is due to Geddes (see *Bibliography* at end of article).

Cell-division.—When the vital processes are so related that income and upbuilding exceed expenditure and dissolution, the cell must obviously accumulate capital and increase in size. In some cases the cell may expand into relatively gigantic proportions, as in the alga *Botrydium* and in many eggs. Growth, however, brings a nemesis with it, this namely, that the mass to be kept alive increases more rapidly than the surface through which the vital processes are accomplished. In spherical cells the former increases as the cube, the latter as the square of the radius. The bigger the cell gets, the more difficult do its conditions of life become. The supplies of food and oxygen,

Fig. 7.

A, Life-history of unicellular plant (*Protococcus*): 1, encysted; 2, quitting its cell; 3, ciliated; 4, quiescent; 5 and 6, dividing. B, Life-history of *Amoeba*: 1, encysted; 2, escaping; 3, free; 4, dividing; 5, free half with vacuole *v*, nucleus *n*, and food-particles *f*; 6, encysting anew. 4 and 5 may also represent the union of two *Amoebae* (conjugation).

the means of accomplishing purification and the like, cannot keep pace with the growth of the living mass if the surface increase only at a much less rapid rate. A limit of growth is thus reached. The cell must stop growing, or go on growing at an increasing risk, or in some way restore the balance between mass and surface. This last course is the one most frequently exhibited—the cell divides. However this may be effected, the result is in all cases the same—namely, the reduction of mass, and corresponding increase of surface. Like other organisms, the cell-organism reproduces at its limit of growth. This rationale of cell-division, due especially to Herbert Spencer, is obviously clearest in reference to free-living cells like Protozoa, Protophyta, blood-corpuscles, reproductive cells, and the like, but the general principle holds good throughout.

It is evident, however, that such considerations as the above go to justify rather than to explain cell-division. They show why the cell ought to divide, not how it does. The real mechanism of the process is still a riddle. In its very simplest expressions, indeed, the riddle may be partly read. In a simple and primitive Protozoon like *Schizogones*, the protoplasm seems literally to break. Irregular fissures appear, as well they might if a condition of unstable vital equilibrium has been

reached, and portions of the substance are cleft apart from the main mass. From such a case to the separation of multiple buds, which are little more than overflowings of too large a cell, or to the commoner occurrence of simple budding, is no great step. The difficulty begins, however, when we consider the ordinary cell-division, which appears in most cases as a deliberate and orderly process, including a well-defined series of nuclear changes. As to the mechanics of this process only a few suggestions of moment have been made. Thus Platner points out that the explanation must be in terms either (1) of chemical processes influencing the cellular substance, or (2) of protoplasmic movement due to the above or to external influences, or (3) of unknown molecular and attractive forces. He himself finds the condition of nuclear division to be in part a streaming movement of the protoplasm, such as is familiar in many Protozoa, and would regard the division of the protoplasm as a purely mechanical process. In his studies on protoplasmic mechanics, Berthold has also attacked this intricate problem, but more in relation to the nature of the dividing partitions than with reference to the forces at work. Professor Van Beneden, who has done so much in working out the details of cell-division in the ovum, has in a recent paper (1887) expressed himself as follows in regard to the deeper problem: 'All the internal movements which are associated with the cellular division have their immediate cause in the contractility of the fibres of the reticular protoplasm which form two antagonistic groups.' All that one can at present conclude is that the process represents, as above noticed, a physiological necessity, and that it takes place in connection with very intricate physical and chemical changes within the cell.

Modes of Cell-division.—After abstracting the rare occurrence of almost mechanical ruptures and of overflow buds, various modes of orderly division remain to be noticed. (a) The cell may give off a bud, usually smaller than itself. With this a portion of the nucleus is usually associated, as in many Protozoa; or the processes may occur apart from demonstrable nucleus, as in the common yeast-plant. (b) Division into two is by far the most frequent mode of multiplication, and occurs all but universally. In a small minority of cases the division is accomplished without any intricate nuclear change, the cell being in an apparently simple way divided into two, with half of the nucleus in each daughter-cell. Such divisions are said to be 'direct.' In most cases the nucleus, apparently taking the initiative, undergoes a striking series of orderly changes before the division is perfect. This is the commonly observed condition, and such divisions are termed 'indirect.' (c) But in many cases the division occurs in a very different way, being not single but multiple. From one cell more than two daughter-cells arise simultaneously, and that not by external cleavage, but by internal multiplication. Such a mode of multiplication is termed endogenous division or 'free' cell-formation, and is well seen in many Fungi and Algae. It may be compared with the ordinary process by defining it as division taking place in limited space and time, since the daughter-cells arise within the mother-cell, and simultaneously, not successively. It is, in many cases at least, preceded by the rapid division of the nuclei, to form centres round each of which protoplasmic material then becomes aggregated. In a few cases, Arnold has described a peculiar breaking up of the nucleus which he called fragmentation.

Karyokinesis.—One of the most beautiful results of recent histology is the demonstration of the general unity of process which obtains in the

division of all kinds of cells. Whether the subject of investigation be the pollen-cells of a plant, the skin of a tadpole, the developing ovum, or the growth of a tumour, the same process of ordinary indirect division may be observed to take place along essentially similar lines. This, though but

Fig. 8.—Stages of Transverse Division :

1, 2, 3, 4, 5, in the epidermis of a tadpole; 1', 2', 3', 4', 5', in the epidermis of lily. (After Macfarlane.)

a natural consequence of common descent and similar conditions, is not without its marvel when the complexity of the process (see below) receives due consideration. Even in detail there is in structural as well as in physiological changes a deep-seated unity of process. But while the essential similarity of all cases of simple 'indirect' division must be allowed, it is only fair to recognise that in minor details very manifold variations occur. Even in those Protozoa where the nuclear changes of division have been followed, considerable diversity of detail obtains; nor, within a single genus do the ova of two different species of thread-worm (*Ascaris*) divide in exactly the same fashion. But neglecting at present the detailed divergences, whether these occur normally and constantly, or as they often do atypically and arbitrarily, it is necessary now to notice the general steps usually observed in cell-division.

We have already described the nucleus as consisting of a readily stainable (*chromatin*) network or ribbon, and of another substance (so-called *achromatin*) which does not stain so deeply. As a preliminary to division, the nucleus loses its definite boundary, and the chromatin threads no longer exhibit the regular disposition they have when at rest. The threads form an irregular wreath, and as the loops break, their arrangement is comparable to a star in which the open ends of the loops are directed outwards, and the closed ends lie in the centre. By subsequent movement this position is reversed, the loops gather into two groups, which lie with their open ends towards one another in the middle. Meanwhile, the achromatin elements also exhibit regular arrangement, forming fine streaks stretching from the centre towards the poles, and exhibiting an appearance which is often compared to a striated spindle. At the two poles of the cell the granules of the general protoplasm

Fig. 9.—Typical Division of Nucleus.

(From Haddon, after Flemming.)

are also aggregated into a couple of star-like figures. The chromatin loops now diverge farther and farther from the centre, till they reach a position at the respective poles. A double chromatin star may then be observed, one at each pole, not to

be in any way confused with unsubstantial polar stars previously mentioned. Soon after this stage is reached, the real cell-division occurs. The protoplasm constricts across the middle of the cell, and the division is accomplished. In plant-cells, and apparently in some animal cells also, the division of the protoplasm is accompanied by the formation of a cellular plate, which bounds the open surfaces of the two daughter-cells. With or without cellular plate, the result is the formation of two daughter-cells, each with half of the original nucleus. But this is not all, the half nucleus formed after the above fashion has to be reconstructed into the original resting form. A series of retrogressive stages occur, in the course of which the nucleus passes from star to wreath, and from wreath into the typical network or twisted coil. In some cases the steps of reconstruction seem to correspond very closely to the various steps of the antecedent upbreathing.

Death.—It seems tolerably certain, as Weismann and others have suggested, that the unicellular Protozoa are in the great majority of cases practically immortal. These simple organisms have no 'body' to keep up, in their functions they appear to be continually self-regenerative, and except from entirely abnormal conditions such cells probably never die. The pool in which they live may dry up for ever, or other animals may swallow and digest them, but such casualties are very different from natural death. They may indeed lose their individuality by doubling in division, or the whole cell may break up into spores, but where there is nothing to be buried we can hardly speak of death. It seems in fact justifiable to say that death began with the formation of a many-celled body. Even there, a certain amount of immortality may be claimed for the reproductive cells, which, becoming separate from the parent organism, proceed to divide into a body which will of course eventually die, but also into reproductive cells, which, as some of them at least will form again fresh organisms and reproductive cells, may be said to be links in a continuous and immortal cellular chain. But leaving aside the really immortal Protozoa, and the logically immortal successful reproductive elements, it must be allowed that cells, like organisms, die. And that not only with the body as a whole, but by themselves. Certain superficial cells are constantly being brushed off and replaced by others; the red blood-corpuscles break up in the fluid; others become hardened in death into the 'mummified' cells of supporting and epidermic structures; others surrender themselves into mucus or in the ejection of lassoes as in the Cœlenterates; others practically die away into fat and reserve products, or may in manifold ways degenerate. Many surfaces, especially in secreting regions of the body, exhibit continual death of cells, and regeneration by the division of the survivors.

IV. Modern Aspect of the Study of the Cell.—With the improvement of appliances and the perfecting of staining methods, the study of the cell has within late years become at once more accurate and more complex. On the one hand, the labours of the early histologists are being amplified and corroborated with ceaseless industry. The forms of cells in different animals and tissues, the minutiae of their structure, the processes observed in their multiplication, are being each year more and more perfectly investigated. On the other hand, the emphasis which has been laid on the protoplasm is finding expression in numerous attempts to explain the forms and phases of cell-life in terms of the underlying protoplasmic changes, and such investigations as those which seek to disclose the mechanics of cell-division and ovum-segmentation, the conditions of cellular equilibrium and change,

or the chemistry of the various parts, mark the limit and high-water mark of cellular biology.

Practical Study.—To gain a preliminary acquaintance with the cell, the student should examine with a good microscope—(1) Free cells as seen in unicellular plants, such as yeast, green mould, simple algae, or in pollen grains, &c.; in unicellular animals like *Amoeba*, *Paramecium*, *Vorticella*; in the elements of the blood; in the ova of animals, as found in spawn of frog, &c. (2) Simple vegetable tissues as seen in root-hairs, transparent leaves, epidermis of plants, and common fresh-water algae like *Spirogyra*; simple animal tissues readily obtained from frog, earthworm, Hydra, and the like. For research in details of structures, staining and section-cutting must be resorted to.

Literature.—(1) For history, see BIOLOGY, HISTOLOGY, MORPHOLOGY, PROTOPLASM; M'Kendrick, *On the Modern Cell-theory* (1888); Drysdale, *Protoplasmic Theory of Life* (1874).

(2) For structure of cell and process of division, consult first modern text-books of histology, such as those of Brass, Fol, Frey, Klein (English), Leydig, Ranvier, and Stöhr. For recent researches, see *Journal of Royal Microscopical Society*. As one research is rapidly superseding another, detailed references need not be given. For general bibliography, see Professor M'Kendrick's paper (above); for nucleus, Van Bambeke, *État actuel de nos Connaissances sur la Structure du Noyau* (Gand, 1885); for cell-division, Waldeyer, 'Über Karyokinese,' *Archiv. f. Anat. u. Physiol.* (1887); for the vegetable cell in particular, Zimmermann, 'Die Morphologie und Physiologie der Pflanzenzelle,' Schenck's *Handbuch d. Botanik* (1887). See also Professor Carnoy's cell journal, *La Cellule*. The Memoirs, which will always be classic in the history of cell-lore, both in themselves and on account of the stimulus which they supplied, will be found in the following and those to which they chiefly refer: Van Beneden, *Recherches sur la Maturation de l'Œuf*, &c. (1883); Flemming, *Zell-substanz, Kern und Zell-theilung* (1882); and later papers in *Archiv. f. mikr. Anatomie*; Frommann, *Unters. über Struktur, Lebenserscheinungen und Reaktionen tierischer und pflanzlicher Zellen* (1884); O. and R. Hertwig, *Beiträge zur Morphologie der Zellen* (1875-88); Leydig, *Zelle und Gewebe* (1885), and previous works; Strasburger, *Zellbildung und Zell-theilung* (Jena, 3d. ed. 1880).

(3) For general physiology, consult first Foster's *Physiology*, chap. i., then general works on physiology of plants and animals—e.g. Sachs' *Text-book of Botany* and *Lectures on the Physiology of Plants*, also Vines' similar work (1887), Hermann's *Handbuch der Physiologie*, &c. Further, Herbert Spencer's *Principles of Biology*; P. Geddes, 'Restatement of the Cell-theory,' *Proc. Roy. Soc. Edin.* (1883); M. Foster's article 'Physiology,' *Encyclopædia Britannica*; Berthold, *Studien über Protoplasma-mechanik* (Leip. 1886); Schwarz, *Die Morphologische und chemische Zusammensetzung des Protoplasmas* (Breslau, 1887); and the article PROTOPLASM.

Celle. See ZELL.

Cellini, BENVENUTO, a celebrated Italian goldsmith, sculptor, and engraver, and the author of one of the most interesting autobiographies ever written, was born in 1500 in Florence, a city which he was forced to quit in early life through having taken part in 'an affray.' He then travelled to Rome, where his skill as an artist in metal-work gained him the favour of the highest nobles and prelates. So anxious were his patrons to secure his services that they allowed him the utmost license of conduct. By his own account he was as expert with sword and dagger as with his goldsmith's tools, and he had apparently no scruple in murdering or maiming any who endeavoured to thwart him. He states that at the siege of Rome in 1527 it was he who killed the Constable Bourbon, and that he afterwards shot down the Prince of Orange before the castle of St Angelo. He stood for a time high in favour with Pope Clement VII., but was eventually flung into prison for the murder of a rival goldsmith. In 1534 he was pardoned

and set free by Paul III., who wished him to engrave dies in the mint; soon afterwards, having spoken contemptuously of the pope's artistic tastes, he was cast into an oubliette of the castle of St Angelo. He escaped through his knowledge of the castle's vaults, but was immediately recaptured, and was only saved from the pope's vengeance by the intercession of Cardinal d'Este. For some years he lived alternately in Rome and Florence, Mantua and Naples. In 1537 he went to the court of Francis I. of France, by whom he was honourably received, and for whom he executed a golden spice-box, the design of which, he tells us, was so exquisite that the king 'uttered a loud outcry of astonishment on seeing it,' and 'could not satiate his eyes with gazing on it.' In Paris he became involved in a lawsuit. Having lost his case, he had recourse, as usual, to his dagger. 'I attacked,' he says, 'the plaintiff who had sued me, and one evening I wounded him in the legs and arms so severely (taking care, however, not to kill him) that I deprived him of the use of both his legs.' This act went unpunished. Having given offence, however, to the reigning favourite at the French court, Cellini returned to Florence, where he worked under the patronage of Cosmo de' Medici, and where he executed his most successful piece of sculpture, the famous bronze 'Perseus with the head of Medusa' of the Loggia de' Lanzi. He began to write his autobiography in 1558, and died at Florence in 1571.

Cellini was a man of versatile fancy, passionately devoted to his art, and his technical skill was supreme. But his designs were often feeble and tasteless, and he seems to have had no sound knowledge of human anatomy. He has, on the whole, been somewhat overrated as an artist, and has been credited with the production of many beautiful cups and vases (such as the 'Cellini vase' in the British Museum) which were really the work of German silversmiths in the 16th century. But he has not been, and could not easily be, overrated as an author. His autobiography is a work of extraordinary interest. 'From the pages of this book,' says Mr Symonds, 'the Genius of the Renaissance, incarnate in a single personality, leans forth and speaks to us.' Though he had not the faculty of self-criticism, Cellini was a shrewd judge of others, and had a remarkable talent for portraying character. His book gives a faithful and a wonderfully vivid picture of Italian society in the 16th century. The animation of the narrative and the racy vigour of the style could hardly be surpassed. The keen insight and unblushing frankness of the writer make his work as fascinating to the student of human character as it is invaluable to the historian of the Renaissance. Cellini reveals all the evil and all the strength of his nature, his vindictiveness, braggartism, and self-worship, no less than his fiery energy and powerful intellect, his splendid self-reliance and passionate love of art. He is the most candid of autobiographers, and he is as ignorant of shame as he is candid. An admirable translation of his work by Mr J. A. Symonds has been published (1887). See also the magnificent monograph by Eugene Plon (1882).

Cellular Plants. It was formerly attempted by De Candolle and others to unite all the lowest plants destitute of vascular tissue (see CELL, and HISTOLOGY, VEGETABLE) under the general title *Cellulares*, as opposed to the *Vasculares*, including all the higher plants. Although this classification is long disused, the term 'cellular plants' is often familiarly employed to distinguish the Fungi, Alge, Lichens, Characeæ, Liverworts, and Mosses (q.v.) from the higher or vascular cryptogams—Ferns, Horsetails, Lycopodiaceæ and Selaginellæ, and Isoetæ. See THALLOPHYTES, VEGETABLE

KINGDOM. For cellular tissue, see also **CELL**, and **HISTOLOGY, VEGETABLE**.

Celluloid, or **PARKESINE**. This substance was first made by Mr A. Parkes of Birmingham in 1835 or 1856. It chiefly consists of a dried solution of gun-cotton (pyroxylin), or of what is nearly the same thing, and oil. A variety of it can be made with pyroxylin and camphor. It resembles ivory, horn, tortoiseshell, and hardened india-rubber, as regards certain properties.

The pyroxylin is prepared by treating Cellulose (q.v.) from such vegetable materials as cotton or flax waste, rags, paper-makers' half-stuff, or paper itself, with a mixture of one part of strong nitric acid and four parts of strong sulphuric acid. It is convenient to call the product so obtained pyroxylin, although the two things are not quite identical. The distillate obtained by distilling wood naphtha with chloride of lime is used as a solvent for the pyroxylin, but other solvents, such as nitrobenzol or aniline, and some camphor are added with advantage. When the excess of solvent is removed from the pyroxylin, it is mixed with a considerable quantity of castor-oil or cotton-seed oil, and made into a dough or paste between heated rollers. For a hard compound the quantity of oil should be less than the pyroxylin, for a soft one it should be greater. Chloride of sulphur is sometimes added to the oil. When articles made of celluloid are in a partially manufactured state, they are soaked in bisulphide of carbon or chloride of lime to remove any trace of solvent, which would render them apt to shrink if allowed to remain. Celluloid is of a somewhat combustible nature unless the substances used to colour it are such as will neutralise this, or unless some non-combustible chemical, tungstate of soda for example, is added to it.

Properties and Uses.—Celluloid has many valuable properties. It is buff or pale brown in colour, but it can be made as white as ivory, which it much resembles, or manufactured in a transparent state. It can be moulded or pressed into any form, and turned, planed, or carved. Neither the atmosphere nor water affects it. It is elastic and can be united by its own cement. In a plastic condition celluloid can be spread on textile fabrics, or it may be made as hard as ivory, for which it is largely used as a substitute. Billiard-balls, piano-keys, and combs are made of it, the latter two articles extensively. It can be coloured to represent amber, tortoiseshell, or malachite. In imitation of red coral it has been a good deal used for jewelry. Like vulcanite, which it excels in durability but exceeds in price, it has very numerous applications. We need only mention brush-backs, knife-handles, buttons, napkin-rings, card-cases, thimbles, and dolls. It is useful for optical instruments and for some surgical instruments. One of the most recent applications of it is for shirt fronts and collars. The manufacture of celluloid, although an English invention, has been most largely developed in the United States, where it is mostly, if not entirely, made by one firm, the Celluloid Manufacturing Co., Newark, New Jersey. It is also made in France.

Cellulose is the substance secreted by the living protoplasm of a vegetable cell to form its investing membrane or cell-wall. (See **CELL**, and **HISTOLOGY, VEGETABLE**, for account of its mode of formation, its ligneous, corky and colloid change, its mode of arrangement and union in cell-walls, &c.). It is obtained in a pure state by treating any unaltered cellular tissue with alkalies and acids to remove mineral matter and protoplasm, and successive washings with water, alcohol, and ether to remove soluble substances. Cotton-pith or vegetable-ivory, although much contrasted in histological properties, are alike remarkably pure cellulose;

in bast the proportion of associated mineral matter becomes much more considerable. Cellulose has the chemical composition $C_6H_{10}O_5$, and spec. grav. 1.52. Among its familiar natural modifications gum is an isomer, and starch-dextrin and grape-sugar are all of similar ultimate composition, while its woody and corky modifications (lignin and suberin) possess an increasing proportion of carbon. Iodine alone stains cellulose yellow or brown, but blue when strong sulphuric acid has been previously added. Strong hot sulphuric acid chars it, while brief immersion in the cold converts it into a tough and dense modification, well known in parchment paper, and prolonged treatment dissolves it altogether. Dextrin may thus be prepared and next transmuted, by boiling the watery solution, into grape-sugar (see **Dextrin**, **GLUCOSE**). By immersion in a mixture of strong nitric and sulphuric acid we obtain Gun-cotton (q.v.), while dilute nitric acid or potash oxidises it into oxalic acid. Ammoniacal oxide of copper dissolves it without change, as is shown by its reprecipitation on dilution. By heating in closed vessels under pressure a dense coal-like mass is formed, while in ordinary dry distillation, gas, tar, and acetic acid are given off, processes which throw light on the formation of coal in nature and on the chemistry of gas-making. In natural decomposition cellulose turns yellow and brown with gradual formation of humus. See **SOILS**.

Although so constant and characteristic a product of vegetable life, the conditions and mode of its formation are still very obscure. From that cell-cycle or rhythm of change between the passive and cellulose-walled state and an active and wall-less one, which is so characteristic of the lowest forms of life, and of which we find surviving traces (e.g. the rejuvenescence of the pollen-grain) in the reproductive processes of even the highest plants (see **CELL**), it would appear that there is some relation between this increased passivity and the formation of cellulose. And in this way arises the speculation that cellulose may be viewed essentially as a (mechanically coherent and thus useful) excretion, an incompletely utilised waste product corresponding to the carbonic acid and water given off by the completer respiratory oxidation and larger evolution of energy of the active phase. Once formed by the plant, it may be again absorbed, as is well seen in the union of a row of cells into a continuous vessel, or in the consumption of endosperm of a seed during germination. Many seeds, such as vegetable-ivory or date, have a great proportion of their reserve material in this form; and this must be digested into glucose by the growing embryo, and again worked up into new protoplasm, which deposits cellulose as before. Like the plant itself, the similar digestive ferments of the animal might thus be naturally expected to digest cellulose; and this is actually, to some extent, the case with the delicate young cell-walls of many green vegetables, as can be experimentally verified, even in man; while in herbivorous animals this power is much developed, and the nutritive utilisation of their fodder is thus increased to an important extent.

The cysts of amœbe and other protozoa appear to be at least largely composed of cellulose, and the external tunic of ascidians (see **Tunicata**) is of identical, or at least isomeric, composition. Cellulose has been described as a pathological product, even in brain-tissue; and Chitin (q.v.), a very characteristic and in many respects comparable animal product, has been sometimes viewed as cellulose in association with a proteid substance.

Celsius, **ANDERS**, the constructor of the centigrade thermometer, was born at Upsala in Sweden, 27th November 1701. He was the grandson of

Magnus Celsus (1621-79), a professor of Astronomy and decipherer of the Helsing runes, and the nephew of Olof Celsius (1670-1756), professor of Theology at Upsala, author of the *Hierobotanicon*, and an early friend and patron of the great Linneus. Anders became in 1730 professor of Astronomy at Upsala. Two years later he set out on a scientific tour, visiting the observatories of Nuremberg, Rome, and Paris. After his return he published his *De Observationibus pro figura telluris determinanda in Gallia habitis* (Upsala, 1738). In 1740 he had the satisfaction of seeing a splendid observatory erected at Upsala, and here he laboured till his death, 25th April 1744. The Inscriptions of the Swedish Academy contain many papers by Celsius on astronomy and physics. It is, however, as the first constructor (1742) of the thermometer now chiefly used by scientific men, that he is best known. In it the space between the freezing-point and the boiling-point of water is divided into one hundred spaces, hence Celsius's thermometer is often called the centigrade or centesimal scale. See THERMOMETER.

Celsus, a Platonic philosopher, but tinged with Epicureanism, who lived in the 2d century after Christ, was a friend of Lucian, and wrote, about 176-180, during the persecution of Marcus Aurelius, under the title *Logos Althēs* ('true word'), the first notable polemic against Christianity. The book itself has perished; but considerable fragments have been preserved as quotations given by Origen in his answer, *Contra Celsum*, in eight books. In the fragments—which are very interesting, as showing the views of a heathen philosopher in regard to Christianity—Celsus, with great acuteness and wit, but without depth or earnestness of thought, prefers against the new religion charges of unphilosophicalness and blind credulity; and especially endeavours to convict Christians of self-contradiction in their spiritual doctrine contrasted with their anthropomorphic representations of Deity; in their religious arrogance contrasted with their confession of sinfulness; and in their views of the necessity of redemption. He also reproaches Christians with their party divisions and ever-varying opinion, and ridicules them as worms in a corner who think they occupy the centre of the world. Celsus holds that the Supreme God can have no contact with the material world, the creation of which is the work of inferior deities or demons. He regards evil as an essential property of the material world; he says: 'There neither has been in former times, nor is there now, nor ever shall be, an increase or diminution of evil. The nature of the universe is ever identical, and the production of evil is not a variable quantity. . . . It is evident that those who sin by nature and by habit cannot be changed in any respect either by punishment or by pardon.' He charges Christians with having 'remodelled "The Gospel" from the "first writing" three times, four times, and many times.' However, as Origen remarked, almost everything of an historical kind to which Celsus refers is to be found in our Gospels, especially the Synoptics. See Keim, *Celsus' Wahres Wort* (1873); Aubé, *La Polémique Païenne in Les Persecutions de l'Eglise* (1878); Pélagaud, *Etude sur Celse* (1878); Froude's *Short Studies*, vol. iv.; and the article on ORIGEN.

Celsus, AULUS CORNELIUS, a Latin physician and writer, who probably flourished about 50 A.D., and wrote not only on medicine, but also on rhetoric, history, philosophy, the art of war, and agriculture. His style is succinct and clear, but full of Grecisms. The only great work of his which survives is the *De Medicina*. The portions relating to surgery are exceedingly valuable, as giving an account of the opinions and observations of the Alexandrian

school of medicine. Indeed, to Celsus, next to Hippocrates and Galen, we mainly owe our knowledge of the medicine of antiquity. Celsus's works were translated into English in 1756. Next to the first edition (1478) the most important are those of Targa (1769) and Darenberg (1859). See Broca's *Conférences historiques* (1865).

Celt (Lat. *celtis* (?), 'a chisel'), a name by which the axe-heads of the early inhabitants of Europe are known among British and French archaeologists. The Scandinavian archaeologists use the word 'axe' and not 'celt.' Its use is now considered pedantic, and it is fast becoming obsolete. The word is generally believed to have originated from a misreading of Job, xix. 24, in the Vulgate, where *Celte*, understood to mean 'with a chisel,' was read in place of *Certe*, 'verily' (corresponding to the 'for ever' of the English Bible). *Celte* or *Celtis* is not elsewhere found in Latin. See *Notes and Queries* (1878), vol. ix. p. 463; vol. x. p. 73.

Celts are either of stone or of bronze. Stone celts vary in length from about 1 inch to 22 inches; but the most common size is from 6 to 8 inches in length, and from 2 to 3½ inches in breadth. They are made of almost every kind of stone, and show considerable diversity of shape, almost all, however, having more or less resemblance to the mussel-shell. The ruder celts are generally of slate, shale, schist, or grit; the finer, of flint, porphyry, greenstone, syenite, or agate. Many of the finer celts are beautifully shaped and highly polished. Some very remarkable examples of this class are in the National Museum of Antiquities, Edinburgh, and one found near St Andrews, in Scotland, is described by Sir David Brewster in the *Philosophical Journal* for 1823. The stone celt was fastened into a handle of horn, bone, or wood.

Bronze celts vary in length from about 1 inch to 8 or 10 inches, the most common length being about 6 inches. They show much greater diversity of shape than the stone celt. As many as four classes have been distinguished by archaeologists: (1) The flat wedge-shaped celt, most nearly resembling the common form of the stone celt. (2) The flanged celt, with the side edges more or less overlapping, and a stop-ridge or elevation between the blade and the part which received the handle. (3) The flanged-edges celt, with side greatly overlapping, with or without the stop-ridge, but with a loop or ear upon one side. (4) The socketed celt, or the celt with a hollow to receive the handle, and generally with a loop or ear upon one side. They are sometimes ornamented with raised lines or circles formed in the mould in which they were cast.

Both stone and bronze celts were probably used for many purposes, serving for chisels, adzes, and axes, as well as for weapons of war, like the stone hatchets of the South Sea Islanders. See under FLINT, STONE AGE, and BRONZE AGE.

Celtiberi, a brave and powerful people of ancient Spain, supposed to have sprung from a blending of the aboriginal Iberians with Celtic invaders from Gaul. They inhabited a large inland district of the peninsula, corresponding to the south-west half of Aragon, nearly the whole of Cuença and Soria, and a great part of Burgos, but the name Celtiberia had often a wider signification, including the country as far south as the sources of the Guadalquivir. The Celtiberi were divided into four tribes, the chief the Arevacæ and Lusones, and were unquestionably one of the bravest and noblest peoples in the peninsula. Their cavalry and infantry were equally excellent. For many years they withstood the efforts of the Romans to subdue them, and it was not till after

the death of Sertorius (72 B.C.) that they began to adopt the Roman language, dress, and manners. The chief cities were Legobriga, the capital; Bilbilis, the birthplace of Martial; and Numantia, destroyed by Scipio Africanus after a desperate ten years' resistance, 133 B.C.

Celtic Ornament, a peculiar development of the system of iron-age decoration prevalent in the British Isles. Its history is divided into two periods by the introduction of Christianity, which engrafted on the older style a number of new elements of decoration brought into the country with the manuscripts of the gospels and psalters, and supplied new forms for the display of these elements, such as churches and crosses, shrines, bells, and crosiers. In its pre-Christian stages, ranging approximately from two or three centuries before the Christian era to about the end of the 6th century A.D., it appears principally in connection with the metal mountings of harness and horse-trappings, and on shields, sword-sheaths, mirrors, armlets, and other articles of personal use and ornament. The material is usually bronze, but occasionally silver or gold. The principal characteristics of the pre-Christian style are its preference for elliptical curves and divergent spirals; its use of chased or engraved lines or dots as a diaper in the spaces of the general design in contrast with other spaces left plain; its use of *repoussé* work, sometimes in very high relief, at other times in low relief on thin plates riveted on in their places in the general design; the production of peculiar patterns often in excessively high relief in the casting; and the employment of *champlevé* enamels of red, yellow, blue, and green, and settings of coloured vitreous pastes. One of the finest examples of such settings occurs in the decoration of an oval shield of bronze, from the bed of the Thames, ornamented with Celtic patterns in relief, enriched by twenty-seven settings of red enamel, kept in their places by small cruciform ornaments of bronze riveted in the centre of each. There are to be seen in the National Museums of London, Edinburgh, and Dublin enamelled shields, sword-sheaths, and ornaments of horse-trappings in bronze, of great beauty and excellence both of design and workmanship, and other articles in bronze, silver, or gold, ornamented in *repoussé* work or in relief, with or without enamel as an enrichment, found in many parts of England, Scotland, and Ireland, in pagan grave-mounds, in crannogs or lake-dwellings, in earth-houses, in the beds of lakes and rivers, or in casual deposits under the soil for concealment. In a work entitled *Horæ Ferales*, Mr Franks of the British Museum has figured in colours many of the best of these remarkable products of the earliest known process of *champlevé* enamelling, and adduced evidence to show that it and this peculiar style of Celtic ornament which accompanies it were of indigenous origin, and at this early period peculiar to the British Isles. The remarkable development of Celtic ornament which succeeded the introduction of Christianity was characterised by the association of interlaced work and fretwork with the elliptical curves and divergent spirals which up to that time had been the principal elements of Celtic design. To these were occasionally added a step-like pattern, and diapers of the Z and I shaped patterns sometimes seen in Chinese decoration. The interlaced work was elaborated with excessive care into patterns, presenting an infinite variety of combinations pleasing to the eye, and capable of being harmoniously treated in colours. It was sometimes a simple ribbon-like band, which might be plain, or divided in the middle, or divided into three by lines close to the margin; or the inter-

lacing band might be replaced by an elongated animal form with its feet, its tail, and its top-knot drawn out to interlace with each other, and with the corresponding parts of other lacertine forms, the whole forming a diaper of quaintly expressed and complicated construction. The fretwork was also elaborated with much ingenuity into most complicated patterns, a special feature of the style being its partiality for diagonal frets and patterns produced by combinations of oblique lines, in direct contrast to the fretwork of Greek and Roman art, which was essentially rectangular. The elliptical curves and divergent spirals of the older style, which had received their only expression in the solid forms proper to metal-work, were found to be equally capable of adaptation to the purposes of the illuminator, and by a similar process of combination and elaboration they also produced patterns and diapers of inexhaustible variety and beauty. A special feature of Celtic decoration was its tendency to divide the surface to be decorated into a series of panels, each of which was treated as a separate whole. The finest examples of Celtic ornament are unquestionably to be found in the grandly illuminated pages of manuscript copies of the Gospels, from the 7th to the 9th century. Of these the most famous for the elaborate nature of their ornament and the beauty of their colouring are the Book of Kells in Trinity College, Dublin, and the Lindisfarne Gospels in the British Museum. Of enamelled metal-work in this period there may be mentioned the Ardagh Chalice, perhaps the most elaborate and beautiful of all the products of Celtic art, the Lismore Crosier, and the Monymusk Shrine. Examples of filigree-work, and chasing or engraving in gold and silver of the highest excellence are found in the Tara Brooch, the Ardagh Brooches, the Rogart Brooches, and the Hunterston Brooch, the Shrine of St Patrick's Bell, the Shrine of St Manchán, and the Cross of Cong. The approximate dates of the metal-work of the highest excellence range from the 10th to the 12th century. For sculpture in stone it is only necessary to refer generally to the incised slabs and sculptured crosses of Scotland and Ireland, ranging from the 9th to the 12th centuries, the special characteristics of their decoration being the same as those of the manuscripts and metal-work already mentioned. For illustrations, see BROOCH, CROSS, SCULPTURED STONES. See further Kemble's *Horæ Ferales*, edited by Latham and Franks (1863); Anderson's *Scotland in Early Christian and Pagan Times* (1881-83); Westwood's *Palæographia Sacra Pictoria* (1845), and *Fac-similes of the Miniatures and Ornaments of Anglo-Saxon and Irish Manuscripts* (1868); O'Neill's *Fine Arts of Ancient Ireland* (1863), and *Sculptured Crosses of Ancient Ireland* (1857); Stuart's *Sculptured Stones of Scotland* (Spalding Club, 1856 and 1867); and Miss Stokes's *Early Christian Art in Ireland* (1887).

Celts. See NETTLE-TREE.

Celts. The Celtic nations of antiquity had no comprehensive name. Those of the Continent were called *Galli* by the Romans, and less usually *Celtæ*. The Greek equivalents for these terms were *Galatæ* or *Galatæ*, and *Keltai* or *Celti*. But neither Greeks nor Romans regarded the British Isles as belonging to the Celtic world. They were situated outside it, and lay over against it in the sea; still it was known to men like Julius Cæsar that certain portions of Britain were inhabited by Celts in the sense of *Galli* or *Belgæ*.

Celtic ethnology involves many difficult questions, and we shall speak of them in this article mostly according to the more palpable distinctions of speech;

and in order to proceed as much as possible from the known to the unknown, we begin by classifying their idioms. These, whether dead or still spoken, belong to the Aryan or Indo-European family of languages, and those of them spoken in modern times divide themselves into two groups—viz. Goidelic and Brythonic. (1) The Goidelic group embraces the dialects termed Gaelic, that is to say, Irish Gaelic, or Irish as it is now more frequently and briefly called; Manx Gaelic, or the Gaelic dialect not yet extinct in the Isle of Man; and Scotch Gaelic, or the Gaelic spoken in the Highlands and Islands of Scotland. In ordinary Scotch and English parlance this is what is understood by the word Gaelic when it is used without any qualification. In order to resist one of the delusions to which charlatans are always leading the unwary, it is right to say that the words *Gael* and *Gaelic* have nothing to do with *Galli*. *Gael* is the simplified English spelling of a word which is now written in Scotch and Irish Gaelic *Gaidheal*, with an evanescent *dh*; but the most ancient form known of it was *Goidel*, whence the adjective *Goidelic*, which has been resorted to by Celtic scholars as applicable equally to all three Gaelic subdivisions of the Celtic group here in question. The Celtic languages of this group are sometimes also called *Erse*, which is a term derived from the Scotch form of the adjective *Irish*; this was *Ersch* or *Yrisch*, the longer and shorter forms of which appear, used without any distinction, by Kennedy in his answer to the poet Dunbar, when the latter had called Kennedy an 'Ersch brybaird' and an 'Ersch katherane,' in reference to his alleged extraction from the Irish Scots of Galloway and Carrick. Kennedy's reply contains the following line (see Murray's *Dialect of the Southern Counties of Scotland*, 1873, pp. 43-44):

Thou luvis nane *Erische*, elf, I undirstand,
and he goes on to add
Thy fore fuler maid *Ersche* and *Erschmen* thin.

(2) The Brythonic group embraces the following languages: Welsh, Breton, and Cornish, which has been extinct now for about a century. Two of these belong to Great Britain, and one, the Breton or Armorican, to Little Britain on the other side of the English Channel. These three might be collectively termed British or Britannie, but that both these adjectives have connotations which would be misleading, as they tend to confusion; so here, also, a neutral form, *Brythonic*, is used, which is derived from *Brython*, one of the Welsh words for the Welsh and the so-called Ancient Britons, whence their language is sometimes called *Brythoneg* in Welsh. This last was in Cornish *Bréthonec*, and in Breton *Brézouek*, meaning respectively the Celtic of Cornwall and of Brittany. *Brython* or *Britto* was the national name of all peoples of this branch, just as *Goidel* or *Gael* may be treated as the national name of the other branch.

All this applies only to the neo-Celtic nations, or those among whom Celtic languages are or have been in use in modern times, and a question of much greater difficulty presents itself when one attempts to classify likewise the continental Celts of ancient history. The reason for this is chiefly the fact that the linguistic data become more precarious as one goes back. Thus, for example, the language of the ruling people of ancient Gaul has been left us only in a very few inscriptions, so that our knowledge of it from that source has to be complemented by the study of Gaulish proper names, of which a considerable number is extant in Latin inscriptions and in the writings of Roman and Greek authors. Now, when we apply the

test of some of the most palpable differences that are known to exist between the Goidelic and the Brythonic idioms to the remains of the Gaulish language, we find at once that it is to be ranked with the Brythonic dialects, and not with the Goidelic ones, and our Brythonic group becomes what may be more exactly described as a Gallo-Brythonic one. This further suggests the question whether there was no continental Celtic idiom which partook of the characteristics of the Goidelic branch. The probability is that there was; for one finds Sulpicius Severus, an ecclesiastical writer of the 4th century, distinguishing between Celtic and Gallic or Gaulish, as if both were spoken in his time. (See Dialogue i. 26, in Migne's *Patr. Lat.* vol. xx. col. 201: 'Tu vero, inquit Postumianus, vel Celtice, aut, si mavis, Gallicè loquere, dummodo jam Martinum loquaris.') And the use of the two names *Celtae* and *Galli* would seem to point to the same inference—viz. the existence in Gaul of two Celtic peoples, the one, probably, superimposed on the other, as on a vanquished population, or driving it towards the south and west. Thus, if the Celtic language which Sulpicius Severus distinguished from Gaulish should be ranked with the Goidelic dialects, we should have alongside of a Gallo-Brythonic group another which might be called Celto-Brythonic were it not inconvenient to use the words *Celt* and *Celtic* in two senses. For while the modern usage applies them indifferently to the whole family, Sulpicius indicates a narrower sense; and so, in fact, had Caesar done centuries before, when he wrote that one of the three peoples of Gaul was called *Celtae* in their own tongue. He states that these *Celtae* proper, so to say, were separated by the Garonne from the Aquitani, and by the Seine and the Marne from the Belge. In other words, their country extended from the Garonne to the Seine and Marne, and other Roman writers give it the name of *Celtica*; and Dionysius of Halicarnassus had heard of a river *Celtus*, from which *Celtica* was supposed to derive its name. From this narrower *Celtica*, in the sense which Roman writers gave it, one might form the adjective *Celtican*, to apply to its people, in order to avoid the confusion which must arise from calling them Celts, whilst using that word also of the whole family.

In order to show the philological reasons for this classification, it would be necessary to go into a variety of details; but let one of these suffice for the present. The Gallo-Brythonic dialects used *p* where the others would have *qu*. Take, for example, the early inscriptional Irish for the genitive of the word for 'son': it was *maici*, corresponding to a nominative which appears as *macc* or *mar* in the oldest manuscript Irish; and *mac* is still the word for 'boy' or 'son' in all the Goidelic dialects. Now the early Brythonic form of this genitive would have been *mapì*, while in the oldest manuscript Welsh we have *map*, and in later Welsh *mab*, 'boy' or 'son.' From this word was formed another, *mabon*, a 'boy' or 'youth'; and this in its old form appears in Latin inscriptions as *maponus* in Roman inscriptions found in Britain in honour of the Celtic god Apollo *Maponus*, so called in reference to his youthfulness. Now from Gaul we have such names as *Eporedorix*, *Parisii*, *Petrocorii*, and many others, with the consonant *p*; but every now and then we have also names with *qu*, such as *Seguana* and *Aquitani*, together with several instances from Spain, where a people of the same Celtic branch as those of *Celtica* had also probably established themselves.

So far, then, as one can get philological data to reason upon, it would seem that the west of Europe had in early times been subjected to two Celtic

invasions; the one is represented by the Celts whose position, geographically speaking, is the farthest from the home of the Aryans. These would be the Celticans of Gaul and Spain, as compared with the Gallic tribes to the east of them towards the Rhine and the Alps; the same relative position is also taken up by the Goidelic Celts of the British Islands, occupying, as we find them doing, the Isle of Man, Ireland, and the Scotch Highlands and Islands. The other, here represented by the Brythons, must have come later and driven out the Goidels, or subdued them, in the rest of this island. This may be supposed, also, to have been the case on the Continent, so that we have to regard the later comers, the Galli, as invaders and conquerors forming another Celtic population. In the eastern portions of Gaul they may have formed the bulk of the population, but in the rest of that country they probably only constituted a ruling class of comparatively small importance in point of numbers. Such a state of things would adequately explain the great dearth of linguistic remains belonging to the older and subjugated people. Roman authors and other strangers would naturally speak most of the ruling classes, and information about the others must reach strangers through the medium of the Gallic rulers and their language, at any rate, so far as concerns the time before Latin became the official tongue of all Gaul. A somewhat similar conclusion has been arrived at by studying the burials and megalithic monuments of France and the neighbouring lands to the east of it. In Central and Western France menhirs, dolmens, and cromlechs prevail, while the eastern side of France shows the prevalence of mounds and barrows, which are here and there found penetrating into the other domain, giving us a sort of rude sketch, as it were, of an invasion advancing irregularly towards the west. See M. Bertrand's *Archéologie Celtique et Gauloise*; also K. von Becker's *Versuch einer Lösung der Celtenfrage* (1883), pp. 114-119.

For reasons already indicated, the question of Celtic ethnology is a very difficult one, but it is considerably more difficult than would appear from what has here been mentioned; for besides two Celtic sets of invaders, there are also to be taken into account the non-Aryan races that previously occupied the countries to which the Celts came. These pre-Celtic populations probably survived in considerable numbers, and one of the effects of a second Celtic invasion may be supposed to have been to force the earlier Celtic settlers to amalgamate with the ancient inhabitants, and to make common cause with them against the later Aryan hordes. So it may be expected that the language of the Goidelic Celts will prove to have absorbed a larger non-Aryan element than that of the Brythons. Similarly, one might take for granted that the physical type of the people speaking the Goidelic dialects should prove less purely Aryan; but this feature is obscured by the fact of the counter-invasions which Wales and other western portions of Britain have undergone in historical times at the hands of Ireland. Lastly, it is right to add that in so far as the people, whose language is or has been Celtic, are Aryans, one might expect the type to be that of tall men, with more or less light hair and blue eyes; on the other hand, the smaller men, with dark hair and black eyes, which it was the fashion till lately to regard as the genuine and typical Celts, are probably not to be regarded as Celts at all, but as Ivernians or representatives of the pre-Celtic and non-Aryan race, whose hunting-ground the soil of the British Islands may be said to have been long before the first Aryan set foot in them.

The Celtic languages and literatures will be found

under BRITANNY, CORNWALL, GAELIC, IRELAND, WALES. See also ARYAN, ETHNOLOGY, PHILOLOGY, DRUIDS.

Besides the works already mentioned, the following should be consulted: Müllenhoff's *Deutsche Altertumskunde* (Berlin, 1887); Windisch's article 'Keltische Sprachen' in the *Allgemeine Encyclopædie der Wissenschaften und Künste*, together with the reviews on the same in the *Revue Celtique*, vol. vi. pp. 395-400; Hübner's *Inscriptiones Britannicæ Christianæ* (Berlin, 1876); Brambach's *Corpus Inscrip. Rhenanarum*; and the volumes of the *Corpus Inscrip. Latinarum*, published by the Berlin Academy, especially those for Britain (vii.), Spain (ii.), Gallia Narbonensis (xii.), Gallia Cisalpina (v.), and Illyricum (iit.).

Cements. These may be roughly divided into three classes: (1) The stone cements, including Roman and Portland cements, and ordinary mortar, which are used in thickish layers for uniting stone and brick work, and for protective coverings to buildings; (2) substances which form binding joints of much less but still appreciable thickness, such as white lead, red lead, and putty; and (3) cements which require to be used in extremely thin coatings, such as glue, isinglass, and dissolved caoutchouc.

Ordinary Mortar is a mixture of slaked lime (*calcium hydroxide*) and sand, made into a paste with water. Generally one part of lime to three or four parts of sand are used, but the proportions vary according to the purity of the lime employed. Very pure or fat lime, such as that made by burning white chalk or white marble does not make so good a mortar as lime obtained from less pure limestones, which are by far the most abundant. The more thoroughly the ingredients are intermixed, the more complete will be the subsequent hardening of the mortar. As commonly laid in the joints of brick or stone work, mortar sets sufficiently fast to allow building operations to proceed from day to day with occasional longer intervals, but it takes years—perhaps in many cases centuries—to reach its maximum hardness. The setting and subsequent slow hardening of mortar are usually considered to be due, in the first instance, simply to the loss of water, and afterwards to the absorption by the lime of carbonic acid from the atmosphere, the carbonate of lime thus formed binding together the sand and stone. It is doubtful, however, if this is an altogether satisfactory explanation. The mortar used in many medieval buildings is largely mixed with small pebbles. In a number of cases this has proved to be of a more durable nature than the stone used along with it.

Puzzolana or *Pozzuolana*, a loosely coherent volcanic sand found at Pozzuoli, near Naples, has been long celebrated for its property of forming a hydraulic cement when mixed with ordinary lime. It is composed of silica, with a little magnesia and potash or soda, alumina, lime, and oxide of iron.

Roman Cement.—Certain natural mixtures of lime and clay are called cement-stones. The clays of some of the newer geological formations in the south of England, for example, contain courses of septarian nodules (see SEPTARIA), which have been in great request for making the best kinds of Roman cement. They are concretions of impure calcareous matter, many of them having this analysis: Carbonate of lime, 66; silica, 18; alumina, 7; and protoxide of iron, 6; or consist of these substances in nearly that proportion. Cement-stones are carefully calcined in kilns, and afterwards ground and sifted. Good Roman cement should set in about 15 minutes, and this quick-setting property makes it valuable for work which requires to be executed between tides and for other purposes where the cement used must harden quickly. It is at best of but medium strength. Some natural

cements are slow-setting, and these do not contain more than 22 per cent. of clay. They set under water when half their weight consists of clay. The proportion of sand used with Roman cement should not much exceed that of the cement. When employed for external coatings of buildings it is apt to effloresce and become unsightly.

Portland Cement.—This is considered by far the most important of the stone cements. It is an artificial product, named from its resemblance to Portland Stone, but is much more largely used than Roman cement. In the manufacture of Portland cement on the banks of the Thames and the Medway by the wet process, three parts of white chalk are mixed with one part of clay or mud from the lower reaches of these rivers. The two substances, along with water, are placed in a 'wash mill' in which strong revolving knives or cutters reduce the whole to a creamy 'slurry' or slip. The slurry then passes by gravitation to backs or reservoirs. There it is allowed to settle for some weeks, when the superfluous water is removed by decantation. The mixture is next dried on heated iron plates or on the floor of a heated chamber, and then burned in kilns. Finally it is ground to a fine powder. Modifications of the wet process by which the large reservoirs are dispensed with have been introduced in recent years. In other parts of the country Portland cement is manufactured by the dry process from the hard limestones of other formations than the chalk, along with clay or shale. These limestones are crushed small, mixed in the proper proportion with clay or shale, then roughly burned, and ground to powder. This powder slightly moistened is passed through a pug-mill, and then made into bricks, which are afterwards burned in kilns and reduced to powder.

Since Portland cement is hardly ever employed in the pure or neat state, its strength is perhaps best tested when it is mixed with an equal weight of sand. The best cement so mixed and moulded in the state of a stiff mortar, into any convenient shape, when tested after the lapse of seven days, during six of which it is customary to keep it immersed in water, exceeds in tensile strength 200 lb. per square inch, and in crushing strength, tested by $\frac{1}{2}$ -inch cubes, 1000 lb. for the same area. Its strength in the unmixed state is much greater. Much of the Portland cement made is, however, little more than half as strong as the best kind. Roman cement of good quality mixed to the same extent with sand as the above, and tested under the same conditions, has on an average a tensile strength of 30 lb., and a crushing strength of 200 lb. in each case per square inch. Portland cement is slow in setting compared with most varieties of Roman cement. Both Portland and Roman cement form *hydraulic mortars*—that is, they set under water. No mortar will do this which contains less than 10 per cent. of silica.

Till close on 1840 Portland cement was hardly known, but the use of it has extended rapidly, especially in recent years. Its most important application is in the construction of docks and harbours, many of which are partly or wholly built of it, mixed with sand and broken stones, in the form of a concrete. In this state, or simply mixed with sand, it is also much employed for other purposes where strength and durability are required. Owing to the nature of some of the extensive engineering works in which Portland cement is largely used, it is plainly of great consequence that its properties should be thoroughly understood. Numerous failures with it have taken place. The chemical investigation into the case of the Aberdeen docks in 1887 distinctly showed the deleterious action of sea-water upon this sub-

stance. But it is also known that objects made of unmixed Portland cement from the works of some of the best makers will sometimes keep good for nearly twenty years, and then crumble to pieces even when not exposed out of doors at all. Of course explanations of these failures are forthcoming. They are generally attributed to carelessness in the manufacture of the cement, or in the selection of the materials for it. But if they occur, as they have done, with cements that have stood very well the ordinary mechanical tests, how can any cement of this kind be entirely depended upon for durability? Twenty, thirty, or even fifty years is far too short a time to test the lasting property of a building material of this nature. The use of Portland cement in pavements and for architectural ornaments is not attended with much risk, and for such purposes it is very suitable. The capital employed in the manufacture in Great Britain is probably near two millions sterling. For American cements, see ROSENDALE.

Scott's Selenic Cement consists of burnt limestone mixed with about 5 per cent. of sulphate of lime in the form of plaster of Paris, and ground to powder. The presence of the sulphate arrests the slaking action of the lime, causes the cement to set more quickly, and admits of more sand being used with it than ordinary lime does. This cement has been a good deal used for plastering, and to some extent also for mortar.

Plaster of Paris (see ALABASTER and GYPSUM).—This material is used for cementing marble and alabaster in much the same way as mortar is in brick-work. It is also employed for uniting the separately moulded pieces of any large object cast in the same material. Sometimes it is selected for fixing metal mounts to glass.

Keene's Cement is made by saturating plaster of Paris in small lumps with alum and recalcining it. It then forms a hard plaster for the projecting portions of halls and rooms, such as pilasters, columns, and skirtings. It is capable of taking a high polish.

Parian or Keating's Cement somewhat resembles Keene's. In its manufacture borax as well as alum is added to the plaster of Paris.

Martin's Cement is another kind, with plaster of Paris for its basis, but instead of borax, carbonate of potash is added, and sometimes hydrochloric acid as well. With the exception of Scott's, these plaster of Paris cements are only used in plastering or other internal work—not for mortars.

Mastic Cement, consisting of a mixture of burnt clay or limestone in a powdered state, with boiled oil and litharge, was more in use formerly than now; but though expensive, it is an excellent material for preventing the admission of rain-water at certain joints about buildings, such as where wood and stone work come together at windows. It was also used for covering external mouldings.

Rust or Iron Cement.—Joints in iron-work, such as those for hot-water pipes, are filled up with a cement of iron borings or turnings, mixed with at least 2 per cent. of sal-ammoniac. Sometimes sulphur in powder is added. The iron oxides and forms a firm joint.

Sulphur Cement.—For jointing earthenware pipes, and occasionally for fixing bars of iron into stone, a cement is made of sulphur, resin, and brick-dust. It is a cheap but not a strong cement where metal is concerned.

Water-glass Cements.—For furnaces one kind consists of burnt and unburnt fireclay made plastic with silicate of soda or water-glass. Another cement, capable of standing a high heat, is formed of asbestos powder made into a paste with silicate of soda. The same silicate mixed with ground glass makes an acid-proof cement.

White and Red Lead Cements.—Either white lead or red lead by itself, or a mixture of both, is much in request as a cement for the joints of slate or glass cisterns, such as aquariums. These are also employed for the joints of gas-pipes, for cementing metal mounts to glass tubes, and other chemical and electrical purposes. White and red lead cements are made up with boiled linseed-oil, and sometimes gold size is added. Mixed white and red lead make a very hard and firm cement. A cement of these two substances and ground plumbago in equal parts, mixed with oil, is said to stand a great heat in steam-joints.

Shell-lac Cements.—An excellent cement is made by digesting 4 oz. of the finest shell-lac in 3 oz. of methylated spirit in a warm place. It should be made into a consistency like thick syrup. This makes a firm cement for mending pieces of glass, china, ornamental stones, and ivory. It is not soluble in water. A cheaper, but still very serviceable cement can be formed by dissolving shell-lac in wood naphtha. For some purposes shell-lac itself is used as cement by simply melting it.

Marine Glue is a mixture of shell-lac in a solution of india-rubber. It is made into thin sheets, and melted when required for use in shipbuilding, &c.

Gelatin and Isinglass Cements.—Fish-glue, gelatin, or Isinglass (q.v.), made up with dilute acetic acid and other bodies into a jelly or thick liquid, produces a cement slightly varying in its nature, for mending china, glass, ivory, bone, and other substances. Foulke's cement and liquid fish-glue are cements of this class. These can be obtained in a convenient form for use in hardware or druggists' shops. They are more or less soluble in water, so that articles mended with them must be quickly washed. Cement of mixed glue and glycerine, sometimes with tannin added, is occasionally used for leather and cloth.

Armenian or Diamond Cement.—The following is the reputed formula for preparing the cement used by the Armenian jewellers for attaching diamonds, &c., without any metallic setting: 'Dissolve five or six bits of gum-mastic, each the size of a large pea, in as much rectified spirit of wine as will suffice to render it liquid; and in another vessel dissolve as much isinglass, previously a little softened in water—though none of the water must be used—in French brandy, or good rum, as will make a 2-ounce phial of very strong glue, adding two very small bits of galbanum or ammoniacum, which must be rubbed or ground till they are dissolved. Then mix the whole with a sufficient heat. Keep the glue in a phial closely stopp'd, and when it is to be used, set the phial in boiling water.'

Elastic Cements.—One part of caoutchouc dissolved in 3 parts of chloroform; also, 5 parts of caoutchouc in 3 parts of chloroform, with 1 part of powdered gum-mastic added. Benzole is sometimes used instead of chloroform as the solvent. Another elastic cement can be made by a mixture of gutta-percha and caoutchouc dissolved in bisulphide of carbon. The solvents of these cements must not be exposed to any but a gentle heat.

Resin Cements.—There are a great number of cements partly formed of ordinary resin. One kind consists of resin 4, beeswax 1, and whiting 1 part. The proportions of these ingredients in the same order for another are 15, 1, and 4. Another is made from resin 4, and plaster of Paris 1 part. These cements are used to fix pieces of stone, glass, &c. to handles when grinding them. Resin, pitch, beeswax, and plaster of Paris or brick-dust are made up in various proportions into cements.

Cutlery's Cement, used for fixing knives and forks

in handles, is made of equal weights of resin and brick-dust melted together; or, for a superior quality, 4 parts of resin, 1 of beeswax, and 1 of brick-dust.

Copal varnish, mastic varnish, Canada balsam, and gold size are each useful occasionally for cementing substances like two pieces of glass together.

Cement-stone, a somewhat argillaceous and ferruginous limestone, generally compact, which is occasionally employed for making hydraulic mortar or cement. The *Cement-stone Series* is the name of a group of strata occurring in the Carboniferous System of Scotland. See CARBONIFEROUS SYSTEM.

Cemetery (from the Greek *koinôtērion*, literally 'a sleeping-place') may mean any graveyard, or other place of deposit for the dead; but it has lately acquired a special meaning, applicable to those extensive ornamental burial-grounds which have recently come into use as the practice of burying within and around churches was gradually abandoned (see BURIAL). The fine burial-grounds of the Turks, extending over large tracts adorned by cedars and other trees, may have suggested the plan to western Europeans. Those round Constantinople are famous, and are dense forests of cypresses. A Moslem grave is never reopened, and a cypress is usually planted after every interment. Of western cities, Paris took the lead in this respect in Britain, and there are now no considerable towns near which there is not at least one cemetery, and the legislation mentioned under the head of BURIAL has rendered their establishment, to a certain extent, a legal necessity. There was at first a natural feeling of regret at the prospect of deserting places of deposit for the dead so hallowed by ancient use and recent associations as the church and the churchyard. On the other hand, the new places of interment began to become attractive in virtue of their trees and flowers, natural scenery, and works of monumental art. The new cemeteries are in many instances cheerful open places, and in them the place of rest for the dead has rather tended to improve than to undermine the health of the living. One of the first and most celebrated of modern European cemeteries is that of Père la Chaise (q.v.), near Paris, the arrangements of which have been generally followed in the cemeteries of London and other English cities. It was laid out in 1804, and is now within the *enceinte* of the city. The *Campo Santo* of Pisa (1228-83), the pantheon of the Pisans, has been the model of many Italian cemeteries. It is an oblong court, surrounded by lofty arcades of marble, and adorned with famous frescoes and works of art. In the centre is a mass of earth brought from the Holy Land. The Genoese *Campo Santo* contains an enormous wealth of sculpture. One Neapolitan cemetery (the *Campo Santo Vecchio*) differs widely from most others. It contains 366 deep pits, one of which is opened each day, and in it all the interments of the day take place. At night a funeral service is performed, and the pit is filled with earth and lime, not to be reopened till the year after. The Sicilian catacombs are also a kind of cemetery. Kensal Green Cemetery dates from 1832; other well-known London cemeteries are those of Highgate and Woking (1855), near Guildford, 7000 acres in area, with a crematory. The Dean Cemetery at Edinburgh, and the Necropolis of Glasgow, are notable; that of Glasnevin, outside of Dublin, is the most celebrated in Ireland. English cemeteries are usually divided into two portions—one consecrated for the burials of members of the Established Church, over whose remains the funeral service is read, and one unconsecrated, for the

burials of dissenters. In the United States great pains are bestowed on the adornment of cemeteries. The most famous are Mount Auburn, near Boston, Greenwood in Brooklyn, and Laurel Hill, near Philadelphia. See BURIAL.

Cenci, BEATRICE, 'the beautiful parricide,' was the daughter of Francesco Cenci, a Roman nobleman of colossal wealth. According to Muratori (*Annales*, lib. x.), Francesco was twice married, Beatrice being the youngest of twelve children by the first wife. After his second marriage, he treated the children of his first wife in a revolting manner, and was even accused of hiring bandits to murder two of his sons on their return from Spain. The beauty of Beatrice inspired him with the horrible and incestuous desire to possess her person; with mingled lust and hate he persecuted her from day to day, until circumstances enabled him to consummate his brutality. The unfortunate girl besought the help of her relatives, and of Pope Clement VII. (Aldobrandini), but did not receive it; whereupon, in company with her step-mother and her brother, Giacomo, she planned the murder of her unnatural parent, into whose brain two hired assassins drove a large nail (9th September 1598). The crime was discovered, and both she and Giacomo were put to the torture; Giacomo confessed, but Beatrice persisted in the declaration that she was innocent. All, however, were condemned and beheaded (10th September 1599). Such is Muratori's narrative. Others allege that Beatrice was the innocent victim of an infernal plot. The results, however, of Bertolotti's investigations (*Francesco Cenci e la sua Famiglia*, 1877), based on original documents and contemporary notices, go far to deprive the story of the Cenci tragedy of the romantic elements on which Shelley's powerful tragedy mainly turns. Francesco, it would appear, was profligate, but no monster: Beatrice at the time she murdered her father was not sixteen, but twenty-one years of age, was far from beautiful, and was probably the mother of an illegitimate son. And Bertolotti further shows that the sweet and mournful countenance which forms one of the treasures of the Barberini Palace in Rome cannot possibly be a portrait of Beatrice by Guido, who never painted in Rome till some nine years after Beatrice's death. See an article in the *Edinburgh Review* for January 1879.

Cenis. See MONT CENIS.

Cenobites. See MONACHISM.

Cenomanian, the name given by French geologists to the Lower Chalk and Upper Greensand of English geologists.

Cenotaph (Gr. *kenotafion*; *kenos*, 'empty,' and *tafos*, 'a tomb'), a monument which does not contain the remains of the deceased. They were originally erected for those whose bones could not be found, as for those who had perished at sea. Latterly the name was applied to tombs built by a man during his lifetime for himself and the members of his family. The memorials in Westminster Abbey to Franklin and Gordon are cenotaphs.

Censer (Fr. *encensoir*, from Lat. *incendo*, 'I burn'), a vase, or other sacred vessel, used for burning incense (q.v.). Censers were used in the Hebrew service of the temple. The ordinary censer, called also a *thurible* (Lat. *thuribulum*, from *thus*, 'frankincense'), used in Catholic services, is a metallic vessel for holding burning charcoal, of brass or latten, silver, silver-plated, or even of gold. It is shaped like a vase or cup, has a movable cover, usually perforated, and is suspended by chains (generally four in number) so as to be swung to and fro for the readier dispersion

of the smoke of the incense, which is thrown upon the live charcoal.

Censors, the name of two Roman officers of state of high dignity, whose duties related to the official registration of the citizens (*census*), the superintendence of public morals (*regimen morum*), and arrangements for the collection of the public revenue and the execution of public works. They were elected in the *comitia centuriata*, presided over by a consul. The term of office at first lasted five years, but was shortly afterwards limited to eighteen months. The censorship was regarded as the highest dignity in the state, except the dictatorship. It was a sacred and irresponsible magistracy, whose powers were vast and undefined, and whose decisions were received with solemn reverence. The census or registration was taken in the Campus Martius, in a building called *Villa Publica*. It was a complete catalogue of the citizens of Rome, stating in detail the age of each, the amount of his property, and the number of his children. Next the censors drew up a list of the equites, entitled to have a horse at the public expense, and made up the roll of senators, supplying the vacancies. The *regimen morum* was the most dreaded and absolute of their powers. It grew naturally out of the exercise of the previous duty, which compelled them to exclude unworthy persons from the lists of citizens. Gradually the superintendence of the censor extended from the public to the private life of citizens. They could inflict disgrace (*ignominia*) on any one whose conduct did not square with their notions of rectitude or duty. For instance, if a man neglected the cultivation of his fields, or carried on a disreputable trade, or refused to marry, or treated his family either too kindly or too harshly, or was extravagant, or guilty of bribery, cowardice, &c., he might be degraded, according to his rank, or otherwise punished. The administration of the finances of the state included the regulation of the *tributum* or property-tax; of the *vectigalia*, such as the tithes paid for the public lands, salt-works, mines, customs, &c., which were usually leased out to speculators for five years; the preparation of the state budget, &c. The office of censor continued to be filled by patricians till 351 B.C., when Censor Marcus Rutilus, a plebeian, was elected. Twelve years later it was enacted that one of the censors (there were always two) must be a plebeian. In 131 B.C. both censors for the first time were plebeians.

Censorship of Press. See PRESS.

Census means the counting of the people. The word is a Latin one, and was applied to the functions which the Roman Censors (q.v.) performed of periodically enumerating the people, but no records of these enumerations remain, and indeed we have but a few scattered notices of them. In Greece a census was established by Solon at Athens for the double purpose of facilitating taxation and classifying the citizens. Religious prejudice prevented any censuses being taken during the middle ages, and it was not till the 18th century that the necessity for obtaining correct information as to the population of European countries overcame this feeling. The first country to undertake a census on a scientific basis was Sweden in 1749; in France an enumeration was made in 1700, but the first reliable was not taken till 1801. In America the first census was taken in 1790, and in England in 1801. Censuses are now taken in Austria, Belgium, Italy, Norway and Sweden, Russia, Switzerland, the United States of America, India, and most of the British colonies, every ten years; in France and Germany every five years; in Spain at irreg-

ular intervals, the next after that of 1860 having been in 1877. The International Statistical Congress, which consists of eminent statisticians from all countries, has done much to improve the taking of censuses, and now several countries, such as Austria, Belgium, Italy, Prussia, Russia, and Switzerland, have statistical bureaux for the purpose, amongst other things, of controlling the taking of the periodical census. In a few countries information as to the religion of the population, and in some cases additional particulars, are obtained, such as the census of 'useful domestic animals' in Norway.

In the United Kingdom the practice is for parliament to pass special acts directing the taking of each census. These acts provide that the registrars of births and deaths shall be the officers through whom the census is to be taken by enumerators, of whom at the census of 1881 there were upwards of 30,000 employed in England alone. All the registrars' districts are so subdivided that no enumerator has more houses than he can conveniently visit in one day. The enumerators have to deliver schedules at all houses, requiring particulars concerning every person who is alive at midnight preceding the census day, and on the census day to collect them. Account has also to be taken of all persons not dwelling in houses wherever found, and of persons travelling, and persons in ships, barges, &c. The enumerators are authorised to require the information necessary for the census, and persons refusing to answer or wilfully giving false answers to the questions are rendered liable to penalties. The particulars to be required in each census are specified in the act directing it to be taken. The Census Act, 1880, required that the census of the following year should show 'the name, sex, age, rank, profession or occupation, condition as to marriage, relation to head of family, and birthplace of every living person who abode in every house on the night of Sunday the 3d of April 1881, and also whether any were blind or deaf and dumb, or imbecile or lunatic.' When the schedules have been collected they are transmitted to the census office, where the work of tabulation, which takes about two years, is carried out. The census when finished is presented to parliament in the form of several bulky volumes. Hardly any two countries agree as to the subjects on which information is demanded; thus some census schedules contain inquiries as to whether there are in the household infirm persons, blind, deaf and dumb, idiots, insane persons, persons who have been convicted of crime; how many languages are spoken by the persons entered; how many are at school; how many exercise the franchise; how many rooms and windows there are in the house, and so on. In 1851 an attempt was made to obtain religious statistics of the United Kingdom; since that year the census shows the religious statistics of Ireland only.

The census of the United States aims at giving a specially full conspectus of the condition of the people, and is illustrated by a large number of maps bearing on almost every branch of the census inquiries. Thus there are maps showing the prevalence of certain diseases; others the area occupied by various crops. The United States census of 1880 extends to 22 volumes. Its compilation took an exceedingly long time, the delay being mainly due to congress having failed to make the necessary appropriations of money for the purpose. The bill prepared for the taking of the census of 1890 proposes a limitation of the scope of the inquiry as compared with the censuses of previous years.

Cent and **Centime** (Lat. *centum*, 'a hundred'), names of coins. The Dutch cent is a copper coin, the 100th part of the guilder (1s. 8d.);

the United States cent is a bronze coin, the 100th part of the dollar, or nearly one halfpenny English, and the Canadian cent has the same value. The centime, the 100th part of the French franc, and of the value of $\frac{1}{10}$ th of an English penny, has been adopted in Belgium, and, under other names, in Greece, Italy, and Switzerland; and the Spanish real (2½d.) also is divided into 100 centimes. The *cental* in the United States, legalised in 1878, is 100 lb. avoirdupois (cf. **CENTNER**). See **DECIMAL SYSTEM**.

Centaurea, a palaearctic genus of Compositae, containing about two hundred species, all herbaceous annual and perennial, of which five or six are natives of Britain. The species most familiar, on account of its beauty, is the blue *C. cyaneus* (see **CORN-FLOWER**), which is sometimes sown as an annual; while its larger perennial ally, *C. montana*, with white or purple ray florets, is a familiar denizen of old-fashioned gardens; *C. americana* is a showy lilac-purple annual (3 or 4 feet); while the oriental Sweet Sultan (*C. moschata*) and Yellow Sultan (*C. amurensis*) are also not uncommon; the latter two being often sold under the name of Amberboa. Among perennials, the large, downy *C. babylonica*, with yellow flowers, is often cultivated; also *C. ragusina* and *C. candidissima*, of which the silver-white pinnate leaves furnish an admired contrast to bright-coloured bedding-plants. Several species (*C. calcitrapa*, &c.) bear the name of Star-thistle, for their spiny involucre. Some are common wayside weeds, often troublesome in pastures, notably *C. nigra*, the Common or Black Knapweed, also called Horse Knot in Scotland; and the closely allied *C. Scabiosa*. The flowers or roots of several species were formerly used in dyeing, and the astringent roots employed by herbalists.

Cen'taurs ('bull-killers'), a wild race of men who inhabited, in early times, the forests and mountains of Thessaly, and whose chief occupation was bull-hunting. Homer, the first who mentions them, describes them merely as savage, gigantic, and covered with hair. They do not appear as monsters, half-man and half-horse, until the age of Pindar. The most ancient account of the Hippocentaurs, sometimes considered as distinct, but more often confounded with the Centaurs, is that they were the offspring of Magnesian mares and Centaurus, himself the offspring of Ixion and a cloud. The Centaurs are celebrated in Greek mythology on account of their struggles with the Lapithae (q.v.), and with Hercules. The most famous was Chiron, the teacher of Achilles and other heroes. In works of art the Centaurs were represented as men from the head to the loins, with the rest of the body that of a horse. It is worth mentioning that the Mexicans, who had no native horses, when they first saw the Spaniards on horseback, believed that the horse and man together made but one animal.

Cen'taury (*Erythræa*), a pretty little annual, genus of Gentianaceae, with pink or rose coloured flowers. They possess the tonic and other medicinal virtues of gentian, and the Common Centaury (*E. Centaureum*) has especially been esteemed in medicine since the days of Dioscorides and Galen; and although no longer in the pharmacopœia, its flower-tops are still sometimes gathered and dried by country-people in England and the Continent; while the allied *Sabbatia angularis* enjoys similar repute in the United States and Canada. The Yellow Centaury is *Chlora perfoliata*; but plants belonging to the wholly distinct composite genus *Centaurea* (q.v.) are also sometimes called Centaury.

Centenarian. See **LONGEVITY**.

Centenary, consisting of a hundred (Lat. *centum*), a period of a hundred years, is now usually employed to signify a commemoration of an event, as the birth (sometimes the death) of a great man. The centenary of Burns's birth was celebrated in 1859; the *bi*-centenary of Pope in 1888; the *ter*-centenary of Shakespeare in 1864. The centenary of American Independence was celebrated by a *Centennial* Exhibition in 1876; the *octo*-centenary of the Bologna University in 1888.

Centering, the framework upon which an arch or vault of stone, brick, or iron is supported during its construction. The simplest form of centering is that used by masons and bricklayers for the arches of common windows and doors. This is merely a deal-board of the required shape, upon the curved edge of which the bricks or stones of the arch are supported until they are keyed in. In building bridges or other structures where arches of great span are to be constructed, the centering is usually made of framed timbers, or timbers and iron combined. The arrangement of the timbers should be such that the strain upon each shall be mainly a thrust in the direction of its length, for if the strain were transverse, a comparatively slight force would snap it, and if a longitudinal pull, the whole structure would be no stronger than the joints holding the pieces of timber together. In arches of great span, a longitudinal pulling strain is almost inevitable in some parts, as a beam of great length would bend to some extent under a thrusting strain. In such cases great skill and care are demanded in the designing and construction of the joints. As an arch is built from the piers towards the keystone, the weight upon the haunches during construction tends to push the crown upwards, and therefore the problem of designing a framed centering involves the resistance of this tendency, as well as the supporting of the weight of the materials. Occasionally, when a very great span is required, and the navigation will permit, piers are built on the bed of the river, or piles are driven into it, to support the centering directly, simplifying it, and at the same time facilitating a more rigid disposition than in centering supported only from the sides. See article BRIDGE for descriptions and illustrations of three types of centering: (1) that for the bridge over the Dee at Chester, Vol. II., page 437, supported directly from the bed of the river; also the centering for the Ballochmyle Bridge; (2) inclined struts in pairs supported from the sides, as Rennie's centering for Waterloo Bridge, page 438; (3) trussed wooden girders supported from the sides, as Rennie's centering for London Bridge, page 438.

Cupolas, like those of the Pantheon and St Peter's at Rome, St Paul's in London, or the flat domes of the Turkish mosques, require very effective centerings.

Centigrade. See CELSIUS and THERMOMETER.

Centipede, a general name for the members of one of the orders of the class Myriapoda. Particularly they are sometimes called Galley-worms, technically Chilopoda. Like the Millipedes, which form the most important neighbour order, the Centipedes are segmented animals bearing jointed appendages, having a well-defined head furnished with feelers and jaws, and breathing by means of air-tubes or tracheæ.

Structure.—The Centipede is like a primitive insect in its general structure.—(a) *Externals*.—The body is divided into well-marked rings, but the region behind the distinct head is practically uniform, and not divisible into thorax and abdomen. Just behind the head a few rings appear to be fused. The number of rings varies from twelve

to more than twelve times as many. In counting the rings the ventral surface should be looked to, for the dorsal shields often overlap. The rings are flattened from above downwards, and each bears a pair of appendages. Dorsally and ventrally the skin is hard and horny. Glands occur in various positions. (b) *Appendages*.—The head, which is covered by a flat shield above, bears (1) a pair of antennæ, usually of considerable length, and consisting of from twelve to over one hundred joints; (2) a pair of small, strong, toothed, and bristly mandibles; (3) a pair of under-jaws, usually with palps. The next appendages are limb-like, and are followed by a modified pair of legs, the basal pieces of which generally meet in the middle line, while the strong joints terminate in a sharp claw, at which a poison-gland opens. These appendages are obviously of use for seizing and killing the prey. The legs of the other segments are usually seven-jointed, sometimes bear spurs and glands, and are generally clawed. The last pair differ in size and form from the rest, and are turned backwards. (c) *Internal Anatomy*.—The large brain is connected as usual with a ventral chain of ganglia. Compound eyes occur in one family, simple eyes in many, while the feelers, certain bristles, and portions of the skin are also sensory. In some cases there is a special well-defined sense-organ of undecided function in front of the head, or on one of the jaws. The alimentary canal is straight, and has associated with it salivary and digestive glands, and excretory (Malpighian) tubules. The heart is represented by a chambered dorsal vessel. Tracheæ or air-tubes open on the sides of the body, sometimes on each ring, often on alternate segments, ramify throughout the tissues, and are connected together on each side by a longitudinal stem. The reproductive organs are usually tubular, and open on the last ring of the body. A distinct penis is sometimes present.

Life and Habit.—Centipedes are darkness-loving animals, nocturnal in their food-hunting, lurking under stones or among rotten wood and the like during the day. Their powers of vision are very poorly developed, and most of the sensory work is tactile. Only in one family (Scutigerridae) are there compound eyes, in most forms only simple eyes, in many none at all. The recent researches of Plateau and others have shown that these creatures can distinguish light from darkness, but do not need eyes to do this; species with eyes do not apparently get on much better than those without them; those with eyes seem to perceive bright objects reflecting much white light, and in some cases conspicuous movements, but probably in no case the forms of objects. Moving actively about at nights, feeling their way by means of their antennæ, which function as a blind man's staff, they light upon insects, worms, and other small animals, which they seize and kill with their poison-bearing appendages. They are all voracious carnivorous forms, not vegetarian like the Millipedes. Some forms can run with some rapidity, and wriggle about in curious serpent-like fashion.

Development.—In some cases the males are said to deposit their reproductive elements in packets (spermatophores) fixed by a web to the ground. In most cases copulation probably occurs. Scolopendra is viviparous, the others lay eggs. The eggs develop into larvæ, which are either miniature adults (Scolopendridæ and Geophilidæ), or differ from the full-grown forms in having only seven pairs of legs (Scutigerridae and Lithobiidæ).

Classification and Forms of Interest.—The order of Centipedes is one of the three or four divisions of Myriapods (q.v.), and, like the class, generally represents a somewhat low grade of development among animals breathing by air-tubes. The most

evolved centipede is a very uniform and old-fashioned animal when compared with any normal insect or spider. In the order itself we distinguish four families—(1) Scolopendridæ, (2) Lithobiidæ, (3) Scolopendridæ, (4) Geophilidæ. The first of these includes curious forms with compound eyes, very long feelers, eight shields along the back, and fifteen pairs of very long legs. The feelers and the last pair of legs are longer than the body; there are external generative appendages. In Scolopendridæ, and apparently in some other centipedes, there are peculiar 'lung-like' dorsal aggregations of air-tubes opening on the back, and perhaps the beginning of the 'pulmonary chambers' of some arachnids. Scolopendridæ is represented by about a score of species, widely distributed in warm countries, and common in houses. In Lithobiidæ, as in the two other families, simple eyes alone are present; there are fifteen pairs of legs, antennæ measuring a third or more of the body length, and fifteen dorsal shields. The genus *Lithobius* includes over one hundred species—*L. forficatus* (of a reddish-brown colour, and about an inch long) is very common throughout Europe and America; our most familiar British species, *L. mutabilis*, also very common, has the habit of feigning death. The bite occasions considerable irritation, like that due to nettle-stings,

Giant Centipede (*Scolopendra gigas*).

The Scolopendridæ have over a score of legs, short many-jointed antennæ, not more than one-fifth of the total length of the body; and simple eyes, not over four pairs in number, or altogether absent. About one hundred species are known, distributed over sixteen genera. They are especially at home in warm countries, where they often attain large size, the *Scolopendra gigas*, for instance, being sometimes a foot long. The poisonous bite of some of the larger forms is really dangerous to man. Scolopendra is the most important genus. Lastly, the Geophilidæ are very long, worm-like centipedes, of somewhat sluggish habit, with 31 to 173 pairs of legs, short feelers, and no eyes. Some 22 species and 9 genera have been recorded, especially abundant in warm climates. *Geophilus electricus* and another species, *G. longicornis*, both found in Britain, shine in the dark. This is probably due to a viscid fluid excreted all over the ventral surface. Hemanthium, found round the Mediterranean, is the largest form of Geophilidæ. Well-developed spinning glands are seen in this family, and their secretion cements together ova and spermatozoa.

Distribution.—The centipedes are world-wide, but abound especially in warm regions. Somewhat unsatisfactory fossil remains have been obtained from the American Carboniferous strata; better preserved possible centipedes have been got from the Solenhofen strata, but it cannot yet be said with certainty that centipedes are known before Tertiary times.

Practical Import.—The centipedes have some direct practical importance as voracious devourers of injurious insects, larvae, snails, and the like, while some of the large tropical forms are known in a somewhat different connection as animals able to give a painful and poisonous bite. In his *Personal Narrative*, Humboldt says he saw Indian children draw large centipedes out of the ground and eat them.

Literature.—Newport, Monograph of the class Myriapoda, order Chilopoda (Trans. Linnean Society, vol. xix. 1845); Haase, *Schlesiens Chilopoden* (1880-81); Latzel, *Die Myriapoden Oesterreichs* (1880-84).

Centlivre, SUSANNAH, an English dramatic authoress, was the daughter of a Lincolnshire gentleman named Freeman, of Holbeach, and born (say some authorities) in Ireland about 1667. Her early history is obscure; but such were her wit and beauty that on her arrival in London, though a destitute orphan, and only sixteen years of age, she won the heart of a nephew of Sir Stephen Fox, who died shortly after their marriage. Her second husband, an officer named Carroll, lost his life in a duel. Left in extreme poverty, his widow endeavoured to support herself by writing for the stage, and after producing a tragedy called *The Perjured Husband* (performed first in 1700), made her appearance on the stage at Bath. She afterwards married (1706) Joseph Centlivre, head-cook to Queen Anne, with whom she lived happily until the time of her death, December 1, 1723. Her plays—*The Busybody* (with 'Marplot' for leading character, 1709), and *A Bold Stroke for a Wife* (1717)—are lively in their plots, and have kept their place on the stage. Nineteen in all, they were collected in 3 vols. 1761, with a biography, and reprinted 1872.

Centner is, with metallurgists, a weight of 100 lb., and it often has this value in commerce. The German centner is however 50 kilogrammes or 110½ lb. avoirdupois. The *cental* of the United States is 100 lb.

Cento, a town of Central Italy, 16 miles N. by W. of Bologna, on a fertile plain near the Reno. It is the birthplace of the famous painter Guercino (q.v.) of Cento. Pop. 4975.

Cento, a name applied to literary trivialities in the form of poems manufactured by putting together distinct verses or passages of one author, or of several authors, so as to make a new meaning. After the decay of genuine poetry among the Greeks, this worthless verse-manufacture came into vogue, as is proved by the *Homero-centones* (ed. by Teucher, Leip. 1793), a patchwork of lines taken from Homer and forming a consecutive history of the fate and redemption of man. It was much more common, however, among the Romans in the later times of the Empire, when Virgil was frequently abused in this fashion, as in the *Cento Nuptialis* of Ausonius, and especially in the *Cento Vergilianus*, constructed in the 4th century by Proba Falconia, wife of the Proconsul Adellius, and giving, in Virgil's misplaced words, an epitome of sacred history. The cento was a favourite recreation in the middle ages. In the 12th century a monk at Tegernsee, named Metellus, contrived to make a cento of spiritual hymns out of Horace and Virgil. See Delepierre, *Tableau de la Littérature du Centon* (1875).

Central America, a name applied to that part of the American continent which lies between the isthmuses of Tehuantepec and Panama, but by some extended to embrace Mexico. It includes the republics of Guatemala, Honduras, San Salvador, Nicaragua, and Costa Rica; Belize; a small part of the Colombian state of Panama; and the Mexican state of Chiapa and peninsula

of Yucatan. See under separate articles; also AMERICA.

Central City, the name of several villages and hamlets in the United States, and of the capital of Gilpin county, Colorado, 40 miles W. of Denver by rail, with quartz-mills and rich gold mines, and (1880) 2626 inhabitants; also of a mining town of Lawrence county, Dakota, in the Black Hills, 280 miles SW. of Bismarck, with some twenty quartz-mills for gold, and a pop. of about 4000.

Central India is the official term for a group of feudatory states in India, which fall into nine political agencies, but are all under the supervision of the governor-general's agent. The region in which these states lie is to the north of the British 'Central Provinces' of India, and touches the North-west Provinces, Rajputana, Khandesh in the Bombay Province, and Chutia-Nagpur in Bengal. The total area is about 75,000 sq. m.; pop. (1881) 9,261,907. The nine subordinate agencies comprised in the Central India Agency are the Indore, Bhil or Bhopawar, Deputy Bhil, Western Malwa, Bhopal, Gwalior, Guna, Bundelkhand, and Baghelkhand agencies. The intrusion of two British districts, those of Jhansi and Lalitpur, belonging to the North-west Provinces, separate these nine agencies into two divisions—native Bundelkhand and Baghelkhand on the east, and Central India proper or Malwa on the west; but the whole country lies between the Nerbudda, the Ganges, and the Chambal rivers, and is mostly fertile and well tilled. The Malwa western division is mainly a tableland 2000 feet above the sea; but its rich black soil produces fine wheat and much opium. The climate of Malwa is on the whole mild and equable; but the northern part of Central India is torrid, and unhealthy during the rainy season. The mineral wealth of Central India is great: iron, coal, copper, and lime are plentiful, and diamonds are found in some parts of Bundelkhand. The inhabitants are very diverse in origin, comprising Mahrattas (the ruling race), Rajputs, Bundelas, Baghelas, Jats, Kols, and hill-tribes such as the Gondas (414,000) and Bhils (217,000). The population is mainly Hindu in religion, only 510,718 being Mohammedans. The agent to the governor-general of India, whose headquarters are at Indore, has very high and very various duties and powers. He is the adviser of all the native chiefs, and their guardian during minority; exercises the functions of a court of appeal; has at his command large bodies of troops; as 'opium-agent' supervises the opium-tax throughout the agency; and he is of course the medium of communication between the imperial government and the native authorities. The principal states and agencies have separate articles. See **INDORE**, **BAGHELKHAND**, &c. The Central Provinces (q.v.) are a British commissionership.

Centralisation, a term which has come into general use for expressing a tendency to administer by the sovereign or the central government matters which would otherwise be under local management. The centralising tendency has been a feature in most of the great states recorded in history, though not in all of them. The oriental empires admitted of a large degree of local independence among the subject peoples. The Roman empire was one of the most remarkable instances of centralisation the world has ever seen. That empire grew out of the subjugation of all the states round the Mediterranean by the city of Rome, and the control of it passed by the inevitable tendency of events into the hands of a single chief, whose power rested on the army, and

who centred in himself all the great functions of government. In the later days of the empire the tendency increased, until the system broke down with the power that wielded it. Amid the chaos that followed the downfall of Rome various systems arose for the restoration of order, political or religious, or both. Of these the greatest is still the Papacy; the greatest in bygone history was the empire of Charlemagne. In those times of struggle, the natural method was centralisation based on military supremacy.

Modern attempts to found a great monarchy in Europe on the model of the Roman empire have failed. There have grown up instead a group of powerful states, in the history of which the centralising tendency is strongly marked. Centralisation was necessary, for in the great struggles which have incessantly been going on, success or even self-preservation could be secured only through a strong organisation repressing internal division, and through large and efficient armies. As an adequate revenue was required for these objects, there was further involved a strong control by the central power of the economic and industrial functions of the state. Thus it will be seen that centralisation is more or less inevitable in the struggle for existence on the European continent. The most notable examples of the opposite tendency at present are apparent in the colonial empire of Great Britain, and in the United States, where we find extensive groups of self-governing communities with only a limited measure of control by the central government. Such control is most limited of all in the British colonies.

On the other hand, in the French commune and in the Russian *mir* we see, under governments otherwise strongly centralised, a form of local activity which had been long extinct in Britain. The municipal reform of 1835 has done much to revive local action in the town life of England. The aim of the reform of local government begun in 1888 is to revive, extend, and systematise local responsibility and freedom of action, particularly in rural districts. It is now recognised that efficiency in the central government can be best secured by transferring local interests to local management by decentralisation. A wise decentralisation may be subservient to an effective centralisation, a principle which holds good also on the European continent. No absolute rules can, however, be laid down for marking off the respective provinces of the central and local powers. Each country must solve the problem in its own way, as its interests and circumstances require.

Central Provinces, a chief-commissionership of India, lying between 17° 50' and 24° 27' N. lat., and between 76° and 85° 15' E. long., and embracing 18 British districts and 15 native states. Area, 113,279 sq. m.; pop. (1881) 11,548,511. The surface is very broken, straggling ranges of hills cropping up even in the level portions. In the north extend the Vindhyan and Satpura (2000 feet) tablelands, with the Nerbudda between; south of these stretches the great Nagpur plain, with the Chatisgarh plain to the east, and a wild forest-region beyond, reaching almost to the Godavari. Besides the two mentioned, the chief rivers of the province are the Wardha and Wainganga; all four are rapid streams, with their crystal waters leaping from point to point, and rushing headlong through the narrow mountain-gorges of their upper course. The climate is hot and dry, except during the south-west monsoon, from June to September, when 41 of the mean annual 45 inches of rain fall. Wheat is grown chiefly in the Nerbudda valley, rice in the Nagpur plain; these are the principal crops, but oil-seeds, cotton, and tobacco are also raised. The only manufactures of note are

weaving and the smelting and working of iron ores. Iron is abundant, especially in the south, and there are also large coalfields, but the coal is of a very inferior quality. There is considerable trade, but its progress is retarded by the want of means of communication; this drawback, however, is being removed, roads are being made, and the railway system steadily pushed forward. Of the population, three-fourths are Hindus, and one-seventh belong to the so-called aboriginal or non-Aryan tribes, who have found a refuge in the Satpura plateau, and still adhere to their primitive faiths (see GONDS). From these hill-tribes the Hindus throughout the province have contracted beliefs and habits which they have grafted upon the usual worship of their sect; adoration of the dead, worship of the goddess of smallpox, and belief in witchcraft are universal. The population is almost entirely rural, only 6 per cent. residing in the 52 towns of above 5000 inhabitants, of which three—Nagpur, Jubbulpore, and Kampti—have over 50,000 inhabitants. Central India (q.v.) is a term of quite distinct meaning.

Centre and Central Forces.—CENTRE OF INERTIA (MASS).—

If m_1 and m_2 be the masses of two particles placed at the points A_1 and A_2 , and if the right line A_1A_2 be divided in B_1 , so that

$$m_1A_1B_1 = m_2A_2B_1,$$

the point B_1 is called the *centre of inertia*, or *centre of mass*, of the two particles. If m_3 be a third mass at A_3 , and if B_1A_3 be divided in B_2 , so that

$$(m_1 + m_2)B_1B_2 = m_3A_3B_2,$$

B_2 is called the centre of inertia of the three particles. In general, if there be any number of particles, a continuation of the above process will enable us to find their centre of inertia. Every body may be supposed to be made up of a multitude of particles connected by cohesion. From this it is obvious that the centre of inertia is a definite point for every piece of matter.

In general, the determination of the centre of inertia requires the use of the integral calculus. In the case of some bodies, such as those which have a simple geometrical form and are of uniform density, elementary mathematical methods will generally be sufficient. Any straight line or plane that divides a homogeneous body symmetrically must contain its centre of inertia. For the particles of the body may be arranged in pairs of equal mass and at equal distances from the straight line or plane; and, since the centre of inertia of each pair lies in the line or plane, the centre of inertia of the whole must also lie in the same line or plane. For example, the centre of inertia of a uniform thin straight rod is its middle point; that of a uniform thin rod bent in the form of a parallelogram, the point of intersection of its diagonals; that of a lamina, uniform in thickness and density and in form a circle, ellipse, or parallelogram, its centre of figure; that of a uniform spherical shell, its centre; that of a homogeneous sphere, its centre; that of a parallelepiped, the intersection of its diagonals; that of a circular cylinder with parallel ends, the middle point of its axis.

An important case is that of a uniformly thin triangular plate. Let ABC be the plate. Bisect AB in P and join CP . Let the triangle be divided by right lines parallel to AB into an indefinitely great number of indefinitely narrow strips. The centre of inertia of each strip is its middle point.

But all the middle points lie on CP . The centre of inertia of the whole plate must therefore lie on CP .

Again, if BC be bisected in Q , and AQ be joined, the centre of inertia of the whole plate must lie in AQ . The centre of inertia must therefore be O , the point of intersection of CP and AQ . It is easily proved by elementary geometry that $OP = \text{one-third of } CP$. Hence, the centre of inertia of a triangular plate is obtained by joining a vertex to the middle point of the opposite side and taking the point two-thirds of this line measured from the vertex. By a similar method the centre of inertia of other plane figures may be obtained.

Fig. 2.

CENTRE OF GRAVITY.—If a body be sufficiently small, relatively to the earth, the weights of its particles may be considered as constituting a system of parallel forces acting on the body. Now, the magnitude of the weight of a particle is proportional to its mass. Hence, the line of action of the resultant of the parallel forces will approximately pass through the centre of inertia. For this reason such bodies are said to have a *centre of gravity*. Strictly speaking, there is no such point of necessity for every body, since the directions of the forces acting on the body are not accurately parallel. Hence, it is only approximately that we can say of a body that it has a centre of gravity. On the other hand, every piece of matter has, as is shown above, a centre of inertia. For all heavy bodies of moderate dimensions it is, however, sufficiently accurate to assume that the centre of inertia and gravity coincide. For example, the centre of gravity of a uniform homogeneous cylinder with parallel ends is the middle point of its axis, that of a uniformly thin circular lamina its centre, and so on.

The centre of gravity of a body of moderate dimensions may be approximately determined by suspending it by a single cord in two different positions, and finding the single point in the body which, in both positions, is intersected by the axis of the cord.

The term centre of gravity is also used in a stricter sense than the one just explained. Thus, if a body attracts and is attracted by all other gravitating matter as if its whole mass were concentrated in one point, it is said to have a true centre of gravity at that point, and the body itself is called a *centrobaric* body. A spherical shell of uniform gravitating matter attracts an external particle as if its whole mass were condensed at its centre. Such a body has a true centre of gravity. When such a point exists, it necessarily coincides with the centre of inertia.

CENTRE OF OSCILLATION.—A heavy particle suspended from a point by a light inextensible string constitutes what is called a simple or mathematical pendulum. For such a pendulum it is easily proved that the time of an oscillation from side to side of the vertical is proportional to the square root of its length for any small arc of vibration. A simple pendulum is, however, a thing of theory, as in all physical problems we have to deal with a rigid mass, and not a particle, oscillating about a horizontal axis. In a pendulum of this kind the time of oscillation will not vary as the square root of the length of the string, for it is obvious that those particles of the body which are nearest the point of suspension will have a tendency to vibrate more rapidly than those more

remote. The former are therefore retarded by the latter, while the latter are accelerated by the former. There is thus one particle which will be accelerated and retarded to an equal amount, and which will therefore move as if it were a simple pendulum unconnected with the rest of the body. The point in the body occupied by this particle is called the *centre of oscillation*.

As all the particles of the body are rigidly connected, they all vibrate in the same time. Hence it follows that the time of vibration of the rigid body will be the same as that of a simple pendulum, called the equivalent or isochronous simple pendulum, whose length is equal to the distance between the centres of suspension and oscillation.

The determination of the centre of oscillation of a body requires the aid of the calculus. It may be stated, however, that it is always farther from the axis of suspension than the centre of inertia, and is always in the line joining the centres of suspension and oscillation. Let A be the centre of sus-

A. pension, B the centre of inertia, and C the centre of oscillation, and let AB be equal to h , and k be the radius of gyration of the body about an axis through B parallel to the fixed axis, then it is easily shown that

$$AC = \frac{(h^2 + k^2)}{h}.$$

Fig. 3. From this there follows the important proposition that the centres of oscillation and suspension are convertible, a proposition which was taken advantage of by Kater for the practical determination of the force of gravity at any station.

CENTRE OF PERCUSSION.—If a body receive a blow which makes it begin to rotate about a fixed axis without causing any pressure on the axis, the point in which the direction of the blow intersects the plane in which the fixed axis and the centre of inertia lie is called the *centre of percussion*. That such a point must exist is easily shown by suspending a straight rod by a long string attached to one end, and striking it with a hammer in different points. If the rod is struck near the top the foot will move in one direction, and if the blow be applied near the foot the top will move in the opposite direction. It is thus evident that there must be some point which does not move at all at the instant of the blow. If a line through this point be regarded as an axis of rotation, the point at which the body was struck is the centre of percussion, since no pressure is produced on the axis. It is easily proved by means of higher mathematics that the centre of percussion with respect to any axis is the same point as the centre of oscillation.

From what has been said it is obvious that in order that no jar may be felt on the hand a cricket ball must be hit in the centre of percussion of the bat with respect to an axis through the hand.

There are, it may be mentioned, many positions which the axis may have in which there will be no centre of percussion. For example, there is no centre of percussion when the axis is a principal axis through the centre of inertia.

CENTRE OF PRESSURE.—When a plane surface is immersed in a fluid at rest, and held in any position, the pressures at different points of the surface are perpendicular to the surface. These pressures may therefore be looked upon as constituting a system of parallel forces whose resultant is the whole pressure. The point at which this resultant acts is called the *centre of pressure*, and may be defined as the point at which the direction of the single force which is equivalent to the fluid pressures on the plane surface meets the surface. The resultant action of fluids on a curved surface is not always reducible to a single force. The defini-

tion given above is, therefore, limited to plane surfaces. In the case of a heavy fluid it is clear that the centre of pressure of a horizontal area corresponds with the centre of gravity. When, however, the plane is inclined at any angle to the surface of the fluid, the pressure is not the same at all points, being greater as the depth increases; since in the same liquid the pressure varies with the depth. In general, the centre of pressure will be below the centre of gravity. The determination of the centre of pressure requires the use of the integral calculus, but special cases may be treated by ordinary algebra. In the case of a parallelogram, one edge of which is in the surface of the fluid, the centre of pressure is at a distance of one-third up the middle line from the base. In the case of a triangle, having one side in the surface of the fluid, the centre of pressure is at the middle point of the median corresponding to the vertex immersed; while in the case of a triangle, with its apex in the surface, and the base horizontal, the centre of pressure is on the median corresponding to the vertex and at a distance of three-fourths of the median from the vertex.

CENTRE OF BUOYANCY.—The pressures which act on every point of a surface immersed in a fluid can be resolved into horizontal and vertical components. The former balance one another. The resultant pressure must therefore be vertical; and, as the pressure increases with the depth, it is clear that the upward pressures must be greater than the downward. Hence the resultant pressure on an immersed body must be a force acting vertically upwards. Now it is easily shown that the magnitude of this pressure is equal to the weight of the fluid displaced. The point in the displaced fluid at which the resultant vertical pressure may be supposed to act is called the *centre of buoyancy*, or *centre of displacement*. Hence, we see that when a body floats in a fluid, it is kept at rest by two forces, the weight of the body acting downwards through its centre of gravity, and the weight of the fluid acting vertically upwards through its centre of gravity, or centre of buoyancy. The relative positions of the centre of gravity and the centre of buoyancy have an important bearing on the safety of ships at sea. If the centre of buoyancy be above the centre of gravity, the equilibrium is stable; in other words, if the ship is displaced, it will tend to return to its original position. If, on the other hand, the centre of buoyancy be below the centre of gravity, the equilibrium will generally be unstable, although a body may float in stable equilibrium even if the centre of buoyancy be below the centre of gravity, as will be explained under the head METACENTRE.

CENTRAL FORCES.—Central forces are forces whose action is to cause a moving body to tend towards a fixed point called the centre of force. By Newton's first law of motion we know that 'every body continues in its state of rest or of uniform motion in a straight line, except in so far as it is compelled by forces to change that state.' From this we learn that, if the speed of a body changes, or if the line of motion be not straight, whether the speed be unaltered or not, some force must be acting. In the latter case the forces acting are called central forces. The doctrine of central forces considers the paths which bodies will describe round centres of force, and the varying velocity with which they will pass along these paths. It investigates the law of the force in order that a given curve may be described, and many other problems which can only be solved by mathematical methods. Gravity affords the simplest illustration of a central force. If a stone be slung from a string, gravity deflects it from the rectilinear path which it would otherwise pursue, and makes it move in a

curve called a parabola. Again, the moon is held in her orbit round the earth by the action of gravity, which is constantly preventing her from going off in the line of the tangent to her path at any instant.

In connection with this subject we have to make some remarks on what is called *centrifugal force*. We have seen that force must always be applied to make a body move in a curved path. Such a force is called a centrifugal force, the old erroneous notion being that bodies have a tendency to fly outwards from the centre about which they are revolving. The use of the term will, however, cause no inconvenience, provided we interpret it merely as indicating that, to keep a body moving in a curve instead of in its natural straight line, a force directed towards the centre of curvature is always required.

Many familiar illustrations of the action of the so-called centrifugal force will occur to the reader. A ball fastened to the end of a string, and whirled round, will, if the motion is sufficiently rapid, at last break the string, and fly off in a tangential path. This is due to the fact that the cohesion of the particles of the string are no longer able to supply the force necessary to keep the ball moving in its circular path. For a similar reason a fly-wheel or a grindstone bursts when it is made to rotate too rapidly. It is found that at a curve on a railway it is the outer of the two rails which is most worn. This is due to the fact that the outer rail has to supply the force necessary to keep the trains moving in curved paths. A glass of water may be whirled so rapidly that, even when the mouth is downwards, the excess of the centrifugal force over the weight of the water is sufficient to prevent the water from falling out. The centrifugal force increases with the velocity. As a matter of fact, it can be shown that when a body moves in a circle of radius r , with velocity v , its centrifugal force is $\frac{mv^2}{r}$. By means of this formula

it can be proved that about $\frac{1}{1600}$ th of its weight is required merely to keep a body on the earth's surface at the equator. By this amount the weight of a body is diminished. Now 289 is equal to 17². Hence it follows that if the earth were to rotate seventeen times as fast as it does now, the attraction of gravitation would only just be able at the equator to keep bodies from flying off its surface. If the rotating body be plastic, it will swell out in all directions perpendicular to the axis of rotation, and assume the form of an oblate spheroid. For the same reason the earth itself has assumed the form of an oblate spheroid, a result which is seen on a greater scale in the case of Jupiter and Saturn on account of their larger size and more rapid rotation.

Centrifugal, a machine. See CLARIFICATION.

Centrifugal and Centripetal are terms used in Botany to designate two different kinds of leaf development or inflorescence, the former term being applied when the development proceeds from the apex towards the base of the axis or leaf, and the latter when it is from the base upwards towards the apex. See LEAF, INFLORESCENCE.

Centrifugal Force. See CENTRE.

Centripetal Force. See CENTRE.

Centumviri ('a hundred men'), a college of justice in ancient Rome, which had jurisdiction in civil cases. It has been supposed that the body was originally made up of three delegates from each of the thirty-five tribes. There were 180 members in the time of Augustus, and under the emperors it increased in importance, as it became the only scene left for the display of judicial eloquence and of legal knowledge.

Centurion (Lat. *centurio*, from *centum*, 'a hundred'), a Roman officer commanding a century or company of foot-soldiers. There were sixty centurions in a Legion (q.v.).

Ceorl, a word which occurs frequently in the laws before the Norman Conquest under somewhat varying senses, but substantially meaning an ordinary freeman not of noble birth. His position gradually sank in social status until it hardly differed from that of the serf, save that the ceorl had the right of choosing his own master in accordance with the law of Athelstan, which required every landless man to find himself a lord. He still remained 'law-worthy,' and paid his *wer-gild* of two hundred shillings; but part of his freedom had disappeared, and ultimately his condition developed into the complete *villennage* characteristic of feudalism. On the other hand, ceorls who possessed land often contrived to force their way into a higher social class, that of the *thegns*, a kind of nobility of service who may be roughly put as equivalent to the *knights* of the period after the Conquest. • A ceorl with 5 hides (600 acres) of land was 'thegn-worthy.' The name ceorl does not occur in Domesday—the very degradation of the meaning of the word *churl* in modern usage is but a part of the historical degradation of the social class which it denoted.

Ceos (sometimes called by the Italianised name of *Zea* or *Tzia*), one of the Cyclades, in the Ægean Sea, 14 miles off the Attic coast. It is 13 miles long, 8 broad, and 39 sq. ft. in area. The central and culminating point is Mount Elias, 1863 feet high. It is fairly fertile, raising fruit, wine, honey, and valonia. The population is 4311, of whom 4295 belong to the capital, *Zea* or *Ceos*. In ancient times Ceos was noted as the birthplace of the poets Simonides and Bacchylides, and the physician Erasistratus; and the Cean laws were famous for their excellence.

Cephalaspis, a genus of fossil Ganoid fishes, of which six species have been described, two belonging to the Upper Silurian, and four to the Devonian measures. The head was protected by a large ganoid plate, sculptured externally with circular radiating markings. The shield was produced into a horn at each posterior corner, and bore a median and posterior dorsal spine. Agassiz gave the name cephalaspis ('buckler-headed') from this extraordinary covering, which has very much the appearance of, and was formerly supposed to be, the cephalic shield of an Asaphus or Trilobite. The body was covered with rhomboidal enamelled scales, and furnished with dorsal and pectoral fins: it terminated in a large unsymmetrical tail. In a graphic description of this fossil in his *Old Red Sandstone*, Miller thus sketches the general appearance of the animal: 'Has the reader ever seen a saddler's cutting-knife—a tool with a crescent-shaped blade, and the handle fixed transversely in the centre of its concave side? In general outline, the cephalaspis resembles this tool; the crescent-shaped blade representing the head, the transverse handle the body.' The endo-skeleton was mainly cartilaginous, retaining the notochord through life. The flexible body, assisted by the large tail and the fins, would give the cephalaspis the power of moving rapidly through the water. Being a predaceous fish, it must have been a formidable enemy to its associates in the Palæozoic seas, for, besides its power of rapid motion, the sharp margin of its shield probably did the work of a vigorously hurled javelin, as in the sword-fish. *Pteraspis*, *Asterolepis* (20 to 30 feet in length), *Scaphaspis*, *Anchenaspis*, and a number of other genera, are united in the same family as Cephalaspis. See Ray Lankester, *A Monograph of the Fishes of the Old Red Sand-*

stone in Britain, part i. 'Cephalaspidae' (Lond. 1868-70); R. H. Traquair, *The Ganoids of the British Carboniferous System* (Palaeont. Society, Lond. 1877).

Cephalodiscus, one of the most curious and interesting organisms dredged by the *Challenger* expedition. It was found in the Strait of Magellan, was first supposed to be a compound Ascidian, was monographed (1887) by Professor M'Intosh as one of the Polyzoa (section Aspidophora), but is regarded by Mr Harmer as closely allied to that marvellous vertebrate-like worm, *Balanoglossus* (q.v.). The organisms form a spreading seaweed-like brownish colony, measuring in some cases 9 inches by 6, and including a great number of little individuals, protected by a membranous, flexible investment or house. Each individual resembles *Balanoglossus* (and also in part backboned animals) in many important points, such as (a) the presence of gill-slits; (b) the existence of a notochord as a dorsal outgrowth from the gut, growing forwards into the anterior region or proboscis; and (c) the possession of a dorsal central nervous system, most richly developed in the middle region (or collar), but extending on to the proboscis. As another apparent connecting link between invertebrates and vertebrates, *Cephalodiscus* is of the greatest zoological interest. See zoology of the voyage of

Cephalodiscus.

H.M.S. Challenger, Part lxii.; Report on *Cephalodiscus*, by Professor W. C. M'Intosh and Mr S. F. Harmer.

Cephalonia (Homeric, *Samē* or *Samos*), the largest of the seven Ionian Islands (q.v.), lies opposite the entrance of the Gulf of Lepanto or Corinth. It is irregular in shape, with a maximum length of 30 miles, and an area of 302 sq. m. Pop. (1879) 80,543. The surface is mountainous, in one point attaining 5310 feet; the soil for the most part thin, and water scarce. The inhabitants, however, have planted vineyards wherever the grape will grow, and currants and olive-oil are also produced for export. The capital is Argostoli (q.v.).

Cephalopoda (Gr., 'head-footed'), the highest class of molluscs, and in some respects the highest invertebrates. They are usually large animals, exclusively marine, with well-developed head-region, but (as the quaint name suggests) with the 'foot' or ventral surface grown round the mouth, and split up into 'arms', which (with one exception) bear suckers. Another part of the foot is

modified to form a funnel through which water is squirted. Two or four gills are present in the usual

Cuttle-fish (*Sepia officinalis*), swimming and at rest.

mantle-cavity. While the ancient forms lived in shells, the Pearly Nautilus alone remains in this state, the shell being in all other cases internal and degenerate. The eyes are peculiarly large, and their ferocious aspect has earned for many common forms the title of 'devil-fish.' The mouth in the midst of the 'arms' is equipped with parrot-like teeth, and with a rasping ribbon on the tongue. The central nervous system, with its closely associated ganglia, is surrounded by a protective cartilaginous sheath, analogous, though in no way homologous, with a vertebrate brain-box. The sexes are separate. The structure and life of these animals will be discussed under the more familiar title CUTTLEFISH; only the general characters, classification, and distribution are here noticed.

Classification.—The Cephalopoda include two distinct orders, one represented by the Pearly Nautilus, the other by all the other living forms, which are again divided into Octopoda and Decapoda, according to the number of the 'arms.'

DIBBRANCHIATA.	TETRABRANCHIATA.
Two gills, kidneys, auricles.	Four gills, kidneys, auricles.
Eight or ten sucker-bearing arms.	Numerous, without suckers.
Shell rudimentary or absent, never external, in one case chambered.	Shell well developed, external, chambered.
An ink-bag.	No ink-bag.
A completely closed funnel.	A split funnel.

Distribution.—Most species occur in warm and temperate seas, but those found in the colder waters seem much more prolific. The Tetrabranchiata are the older forms, and begin in the Silurian, whereas the Dibranchiata first appear in Triassic times. The Ammonites (q.v.) are the most familiar representatives of the former, the Belemnites (q.v.) of the latter.

See especially CUTTLEFISH, NAUTILUS, BELEMNITE, AMMONITE; also CALAMARY, OCTOPUS, SEPIA, SQUID; Owen, *Memoir of the Pearly Nautilus* (1832); Férussac and D'Orbigny, *Histoire naturelle des Céphalopodes* (2 vols. Paris, 1835-48); Hoyle, *Challenger Report on Cephalopoda*.

Cephaloptera, a name formerly used for a genus of rays. See RAY.

Cephissus, one of the two rivers which water the Athenian plain. It rises on the western slope of Mount Pentelicus and the southern side of Mount Parnes, and flows past Athens on the west into the Saronic Gulf near Phalerum.

Cepola. See BANDFISH.

Ceram' (SERANG), the largest island of the southern Moluccas, lies NE. of Amboyna, to which Dutch residency it belongs, and is divided into Great and Little Ceram by the Isthmus of Taruno. Area, 6605 sq. m.; pop. 195,000. The island is one of the least explored in the archipelago, and comparatively little is known of the interior, which is, moreover, but scantily populated, the great mass of the people, mostly native Alfuros and immigrant Malays, inhabiting the coast villages. Much of the island is very fertile. A mountain-chain runs through the country, reaching in Nusa Keli some 11,000 feet. The chief exports are sago, iron, timber, earthenware, birds of Paradise, dried fish, edible nests, &c.

Ceram'ics (Gr. *keramos*, 'potter's clay'), a term used to designate the department of plastic art which comprises all objects made of clay, such as vases, cups, bassi-rilievi, cornices, and the like. See POTTERY.

Cerastes, or HORNED VIPER, a genus of serpents of the family Viperidae, distinguished by a broad depressed heart-shaped head, the scales of which are similar to those of the back, and particularly remarkable for the development of one of the scales of each eyelid into a spine or horn, often of considerable length. The tail is very distinct

Horned Viper (*Cerastes vulgaris*).

from the body. This genus is exclusively African, and very venomous. There is probably only one species, *Cerastes aegyptiacus* or *cornutus*, the Horned Viper of the north of Africa, called *Cerastes* by the ancients, the name being derived from the Greek *keras*, 'a horn.' It was correctly described by the traveller Bruce, but his description was for some time regarded with incredulity.

Cerate (Lat. *cera*, 'wax'), a compound of wax with other oily and medicinal substances in such proportions as to have the consistence of an Ointment (q.v.). Simple cerate is made by melting together 6 parts of olive-oil, 3 of white wax, and 1 of spermaceti.

Ceratites, a genus of Ammonites (q.v.) peculiar to, and characteristic of, the Trias.

Ceratodus, the Queensland mud-fish, one of the remarkable sub-class of double breathers or *Dipnoi*. The name was originally used for the fossil possessors of certain tooth-plates found in the

Ceratodus.

Triassic and Jurassic strata, and to this genus the Queensland survivor, which has similar dental arrangements, was referred when discovered in 1870. *Barra munda* is the local name. The fish may occasionally attain a length of six feet, has a later-

ally compressed body with large scales, and possesses very unfish-like limbs with a central jointed axis and lateral pieces. It lives in muddy water often containing much decaying vegetable matter. In this medium it does not find the gill-respiration sufficient, and comes to the surface to take gulps of air into the swimming-bladder, which functions as a lung. It eats leaves and other parts of plants. At nights *Ceratodus* sometimes leaves the water, and moves along the river-bank. The expulsion of air from its air-bladder or lung is supposed to account for a grunting noise then often heard. In the dry season it buries itself in the mud.

Limb of *Ceratodus*.

The flesh is much esteemed, and compared with salmon. This interesting animal will be discussed, in its more technical relations, along with its neighbour genera—*Lepidosiren* and *Protopterus*—under the title MUD-FISHES.

Ceratonlia. See CAROB.

Cerberus, in Greek Mythology, the many-headed dog—according to Hesiod, the offspring of Typhaon and Echidna—who guarded the portal of the infernal regions. Later writers describe him as only three-headed, with the tail and mane composed of serpents, though the poets sometimes encumber him with a hundred heads. Orpheus charmed him by the magic of his lyre, and Hercules overcame him by strength and dragged him to the upper world.

Cercaria, the technical name applied to an embryonic form of many flukes. In the two-suckered flat parasitic worms (the Distomae division of Trematodes) the development is indirect or circuitous. The eggs develop into embryos, which, instead of growing into adults, produce asexually one or more sets of intermediate forms. The final form, produced more or less directly from the embryo, is called a cercaria, and grows up into the adult fluke. It differs from the adult in having only rudiments of reproductive organs, in possessing eye-spots, and in being (except in one genus) equipped with a very movable tail. It is (1) born within some host, such as a water-snail; (2) leaves this and swims freely in the water; (3) becomes sluggish, and enters a second host, or fixes itself on some foreign body. In this state it loses its tail and encapsules itself, and does not experience any further change till (4) it or its host is eaten by a vertebrate, within which the cercaria becomes an adult and sexual fluke. From the latter the embryos which eventually enter the first-mentioned host arise. Sometimes the life-history is simpler, but in all cases the cercaria is the form produced (generally indirectly) by the original embryo, and developing into the adult. See FLUKE.

Cercis. See JUDAS' TREE.

Cercopithe'cus (Gr., 'tail-ape'), a genus of Monkeys (q.v.).

Cere. See BILL.

Cerealia, or CEREAL GRASSES, so named from Ceres (q.v.), are the plants which produce grain or corn; in strictness, all the species of grasses (Gramineae) cultivated for the sake of their seed as an article of food. They are also called Corn-plants or Bread-plants; but in this wide

popular sense the term cereal ceases to have any botanical limits, and includes plants of wholly distinct orders, notably Buckwheat (natural order, Polygonaceæ), and Quinoa (Chenopodiaceæ), &c.; even the Lotus of the Nile, the *Vicia taria regia*, and other species of water-lilies might thus be added to the list.

The cereals proper do not belong to any particular tribe of the great order of grasses, but the employment of particular species as bread-plants seems to have been determined chiefly by the superior size of the seed, or by the facility of procuring it in sufficient quantity, and of freeing it from its unedible envelopes. The most extensively cultivated grains are Wheat (*Triticum*), Barley (*Hordeum*), Rye (*Secale*), Oats (*Avena*), Rice (*Oryza*), Maize or Indian Corn (*Zea*), different kinds of Millet (*Setaria*, *Panicum*, *Paspalum*, *Pennisetum*, and *Penicillaria*), and Durra or Guinea Corn (*Sorghum* or *Andropogon*). These have all been cultivated from time immemorial, and there is great uncertainty as to the number of species to which the many existing varieties belong; their original forms and native countries often cannot confidently be determined. Barley, oats, and rye are the grains of the coldest regions, the cultivation of the former two extending even within the arctic circle. Wheat is next to these, and in the warmer regions of the temperate zone its cultivation is associated with that of maize and rice, which are extensively cultivated within the tropics. The millets belong to warm climates, and Durra is tropical or sub-tropical. Rice is the food of a greater number of the human race than any other kind of grain. See CORN, BARLEY, MAIZE, MILLET, RICE, WHEAT, and other separate articles.

Cerebration, UNCONSCIOUS. There can be no doubt that molecular changes in the cerebrum accompany all our conscious mental processes. The doctrine of unconscious cerebration as stated by Carpenter, Laycock, and others, holds that similar changes may go on in the cerebrum without any consciousness on our part, until the fully elaborated mental result is presented. It is an every-day experience that after one has been in vain trying to recall some name or incident, it will suddenly flash into the mind when one is thinking of some entirely different subject. According to Carpenter the cerebrum put in action by our consciousness has gone on working automatically but unconsciously, until the processes accompanying the mental operation of remembering the name or incident have been completed. This is the physiological statement corresponding to the psychological doctrine that the mind may undergo modifications without being conscious of the process until the new combination is presented to consciousness. See CONSCIOUSNESS, MIND.

Cerebro-spinal Fluid is a clear, almost colourless, slightly alkaline fluid, closely resembling lymph in its composition, but containing less albumen. It is contained partly within the ventricular system of the brain, and in part in the loose connective tissue (subarachnoid meshwork), which lies between the Arachnoid and Pia Mater (q.v.), being continued from this latter situation along the lymphatic sheaths, which closely invest all the blood-vessels in the substance of the brain and spinal cord. The spaces which contain it communicate with the lymphatics of the head and of the nerves, and with the venous sinuses in the dura mater. Its main function, besides that of removing waste products, is to equalise the pressure within the skull. As the blood pressure increases that of the cerebro-spinal fluid diminishes, and *vice versa*. As the brain atrophies it is replaced by a proportionate increase in the fluid. In some dis-

eases, such as acute and chronic Hydrocephalus (q.v.), it is greatly increased, and then it becomes a cause of atrophy of the brain. Its value as a water-cushion in diminishing the violence of shock from external injury has been already referred to at BRAIN. *Cerebro-spinal* means pertaining to the brain and spinal cord together, to the cerebro-spinal system. For Cerebro-spinal Meningitis, see MENINGITIS.

Cerebrum. See BRAIN.

Ceremonies, MASTER OF THE, an officer at court, instituted by James I. for the reception of ambassadors and dignitaries. The same name came to be used for the supreme authority on etiquette at public assemblies at Bath and elsewhere; Beau Nash (q.v.) being the most memorable.

Cereopsis (Gr., 'wax-face'), a genus of birds of the family Anatidae, to which the New Holland goose (*C. nova hollandie*) belongs. This bird has been known since the southern shores of Australia were first visited by navigators. There, and on the adjacent islands, they were found in great abundance; and so little were they acquainted with the danger to be apprehended from man, that the earlier navigators easily supplied themselves with fresh provisions by knocking them down with sticks. The flight is slow and heavy, and the bird is naturally becoming less abundant. The cere (see BILL) is remarkably large, whence the name.

Ceres, the Roman name of the great Greek goddess Demeter, the protectress of agriculture and the fruits of the earth. Her worship was borrowed by the Romans from Sicily. Her first temple in Rome was vowed by the dictator A. Postumius Albinus (496 B.C.), to avert a famine with which the city was threatened. A great festival, with games, the *Cerealia*, was instituted in her honour, and her worship acquired great importance in the city. The decrees of the senate were deposited in her temple for the inspection of the tribunes of the people. See DEMETER.

Ceres, one of the Planetoids (q.v.), and the first of them that was discovered. It was first seen by Piazzi at Palermo, January 1, 1801, and is sometimes visible to the naked eye, looking like a star between the seventh and eighth magnitudes.

Cereus, a large genus of Cactaceæ (q.v.), containing many of the most imposing forms of the order, both as respects vegetation and flowering. *C. giganteus* reaches a height of 60 feet, often unbranched, its tall pillars giving an extraordinary character to the landscape of New Mexico, while the allied *C. peruvianus* (36 feet) takes its place in Peru. Others have thin snake-like branches (*C. flagelliformis*), while the short obconical *C. senilis* is covered with long silky hairs. Many have splendid flowers, and of these *C. speciosissimus* with scarlet or purplish flowers is often cultivated, while *C. grandiflorus* is the well-known night-flowering cactus. The fruits are often much esteemed. For illustration, see CACTUS.

Cerignola, a town of Italy, 22 miles SE. of Foggia by rail, with manufactures of linen, and a trade in almonds and cotton. The Spaniards' decisive victory over the French here in 1503 established Spain's supremacy in Naples. Pop. 22,650.

Cerigo, the southernmost of the seven Ionian Islands (q.v.), now officially known again by its old Greek name of *Cythera*, is separated from the coast of Morea by a narrow strait. Area, 107 sq. m.; pop. (1879) 13,259. It is mostly barren and mountainous in some parts; but corn, wine, and olives and fruits are raised. Capsali is the capital. In ancient times the island was sacred to Venus, as the land that received the goddess when she arose from the sea.

Cerinthus, a heretic who lived at the close of the apostolic age, but of whom we have nothing better than uncertain and confused accounts. He is said to have been a native of Alexandria. He passed from Egypt into Asia Minor, and lived in Ephesus contemporaneously (according to the belief of the church) with the aged apostle John. It is related by Irenæus, on the authority of Polycarp, that John held the heretic in such detestation that, on a certain occasion, when he encountered Cerinthus in the baths of Ephesus, he immediately left the baths, saying to those about him: 'Let us fly, lest the bath fall on us, since Cerinthus is within, the enemy of the truth.' It is also said by Irenæus that the Gospel by St John was written in direct opposition to the tenets of Cerinthus. He held that the world was not made by the highest God, but by some angel or power far removed from and ignorant of the Supreme Being. He is also said to have held coarse and sensual millenarian views, to have believed the Jewish ceremonial law to be in part binding upon Christians, and to have taught that the Divine Spirit was first united with the man Jesus in his baptism by John. Cerinthus being, so far as is known, the oldest teacher of Judaico-Gnostic principles, and, according to Neander, 'the intermediate link between the Judaising and Gnostic sects,' there would naturally be a greater incongruity and want of harmony in his system than in the later developments of Gnosticism (q.v.).

Cerithium, a genus of Prosobranchiate Gastropods, and type of a large family, Cerithiada. The shell is rough, naked, spiral, elongated, with many coils, and with an oval oblique aperture which has a short canal in front. The species of this family are numerous (140), most of them marine, but many inhabiting estuaries and brackish rather than salt water; some are found in lakes and rivers. A few belong to temperate climates, but most of them are tropical, and in mangrove swamps they particularly abound. The fossil species are very numerous, and almost all limited to the Tertiary formations. *C. vulgatum*, over six inches in height, is often seen in Italian markets.

Cerium (syn. Ce, eq. 92) is a rare metal found in cerite and a few other minerals. It is a white metal, has not been obtained in any quantity, is not therefore employed in any manufacture, and forms two basic oxides and a numerous class of salts. The nitrate and oxalate of cerium have been employed in the vomiting of pregnancy, their action being somewhat similar to that of the subnitrate of bismuth. Cerium biscuits are biscuits containing a small proportion of the oxalate, and they form a very convenient medium for the administration of the salt. *Cerite* or *Ochroite* is the silicate of cerium, and is found as a mineral in gneiss, near Riddarhytta, in Westmanland in Sweden.

Ceroxylon. See WAX PALM.

Cerreto, a cathedral city of South Italy, on a slope of the Apennines, 14 miles NNW. of Benevento. Pop. 5129.

Cerro de Pasco, the capital of the Peruvian department of Junin, stands at an elevation of 14,276 feet, 138 miles NE. of Lima. Near it are some of the richest silver-mines on the continent. The climate is cheerless and inclement. Pop. 7000, mostly Indians and half-breeds.

Cerro Gordo, a plateau in Mexico, the most easterly on the route from Vera Cruz to the capital. Here, on 18th April 1847, the Americans totally defeated the Mexicans.

Cerro Largo, a department in the NE. of Uruguay, well watered, with large savannas and

forests. Area, 5735 sq. m.; pop. (1884) 36,000, chiefly engaged in cattle-raising. Capital, Cerro Largo or Melo; pop. 5000.

Certaldo, a town of Central Italy, 19 miles SW. of Florence (37 by rail). It is noteworthy as the residence of Boccaccio, who was born and died here. His house is still standing, much as it was in the poet's time. Pop. 2500.

Certhiidae, a family of birds, generally placed in the great order Insectores or Passeres. They are best known by their most typical representatives the Creepers (q.v.). They are widely distributed birds, absent however from the Ethiopian and neo-tropical regions, and the family includes twelve genera and about fifty species. They are expert climbers, and feed on insects.

Certificate, in the law of England and of the United States, is a written statement by a person having a public or official status concerning some matter within his knowledge and authority. There are a great many classes of such certificates—e.g. certificate of charge upon land; certificate of the chief-clerk in Chancery proceedings, which is practically a report of what the clerk has done; certificate of discharge of a debtor in liquidation; certificate of incorporation under the Companies Acts; certificate of mortgage on ships under the Merchant Shipping Acts; certificate of naturalisation. In the United States, the word is commonly applied to any formal statement made by a public servant in the execution of his duty, as by a collector of taxes, a postmaster, &c. See CHARACTER.

Certification, in the law of Scotland, signifies the judicial assurance given to a party of the course to be followed by the judge in case he disobeys the will of a summons, or other writ or order of the court. Reiterated contumacy on the part of the defender was at one time punished with confiscation of his property (1449, chap. 29), but now certification merely means that if he fails to appear in the usual manner, the judge will decern, or pronounce judgment against him.

Certiorari is the writ by which, since the abolition of imprisonment for debt and the consequent disuse of the better known writ *habeas corpus*, causes are removed from inferior courts of record into the High Court of Justice. This is a matter of considerable importance to the commercial public. Such removal is either before or after judgment in the inferior court. Before judgment certiorari is competent as tort, in all cases except where the sum sued for is less than £5. Either party can remove the cause, but, where the sum is less than £20, the defendant must give his sureties for the debt and costs. The removal must be within six weeks after appearance of defendant. In the superior court the plaintiff must make a fresh statement of claim. The certiorari is obeyed by sending up the original record. Under the Judicature Acts there is a further power of removal when any defence or counter-claim is set up which is beyond the jurisdiction of the inferior court. In the county courts, where the action on contract is above £20, or on tort above £5, the defendant has a general right to certiorari on security for costs. Where the discretion of the superior court is appealed to, such considerations as the difficulty of legal points, the improbability of obtaining an impartial jury, are important. After judgment, certiorari is often applied for by the successful plaintiff for purposes of execution, where the person or effects of the defendant cannot be found in the jurisdiction of the inferior court. Certiorari may also be obtained as of right by the crown to remove an indictment in a criminal cause to the Queen's Bench Division or the Central Criminal Court. This writ used also to be of right to private

prosecutors, but since the institution of the Court of Criminal Appeal it is necessary to show cause, as in a civil case from the county courts, and to give security.

In the United States, *certiorari* is generally provided for by statute, but where no such provision is made, or no other mode of review of the proceedings of an inferior court has been provided by statute, any superior court exercising common law jurisdiction has an inherent right to issue this writ. It is used in both civil and criminal cases to bring the whole record of the inferior tribunal before a superior court, to determine whether the former has proceeded within its jurisdiction, and also to enable substantial justice to be done whenever an inferior tribunal has failed to proceed according to the requirements of the law. It is used as an original process to remove a cause, and change venue, only where the superior court is satisfied that an impartial trial will not otherwise be had.

Certo'sa di Pavi'a, a celebrated Carthusian monastery, 5 miles N. of Pavia, was founded in 1396 by Giovanni Galeazzo Visconti, first Duke of Milan, in atonement for the murder of his uncle. The church is a splendid structure in the form of a Latin cross, the ground-plan being 252 feet long by 177 feet broad. The richly sculptured facade, designed by Borgognone, was commenced in 1473. The building is made up of various styles, but the Pointed prevails in the interior, which is decorated with frescoes, paintings, &c., and contains a gorgeous high-altar, the mausoleum of the founder, and several monuments. After the battle of Pavia (1525), Francis I. was for three days a prisoner at the Certosa, which, since the dissolution of the monasteries, has been constituted a national monument. The name *certosa* is a form of Carthusian (q.v.), and is used of other monasteries of the order, as that to the south of Florence.

Ceru'men is ear-wax, the yellow waxy matter which is secreted by certain glands lying in the passage that leads from the external opening of the ear to the membrane of the tympanum. It lubricates the passage and entangles particles of dust and small insects, preventing them from getting farther in. See EAR.

Cervantes Saavedra, MIGUEL DE, the author of *Don Quixote*, was born at Alcalá de Henares in 1547. His birthday is unknown, but he was baptised on the 9th of October. He was a descendant of a family that traced its origin back to the 10th century through a line of Castilian nobles, of whom one was the renowned warrior Nuño Alfonso, whose grandson took the surname of Cervantes from the old castle of San Servando, or Cervantes, near Toledo. It was borne with honour by many church dignitaries, soldiers, and magistrates of the 14th and 15th centuries, but at the birth of the man who gave it immortality it had ceased to be one of the prominent names of Spain. The name of Saavedra came into the poet's branch of the family by marriage in the 15th century. Of Cervantes personally we know little or nothing beyond what he himself tells us, but of the events of his life there is a tolerably complete record. The story of his having studied at Salamanca is improbable; all we know of his education is that Juan Lopez de Hoyos, a professor of belles-lettres at Madrid, calls him his 'dearly beloved pupil.' The first known productions of his pen appeared in 1569 in a collection of pieces on the death of the queen, edited by the professor. Early in the same year he passed over into Italy in the service of Cardinal Giulio Acquaviva, but shortly afterwards enlisted as a soldier under the command, it would appear, of Marc Antony Colonna. At the battle of Lepanto he was in

the thick of the fight, and received three severe gunshot wounds, by one of which his left hand and arm were permanently disabled. After having seen some further service against the Turks in Tunis, he was returning to Spain in 1575 with letters of recommendation to the king from Don John of Austria and the Viceroy of Sicily, when the galley he sailed in was captured by Algerine corsairs, and with his brother Rodrigo and several others he was carried into Algiers. He remained in captivity five years, during which he made four daring attempts to escape, and lived in almost daily expectation of death or torture. It was not for himself alone that he sought freedom. No nobler story of unselfish heroism has ever been told than that in the depositions of his fellow captives at Algiers, where they testify to his self-devotion, his dauntless spirit, and his generosity, and with touching earnestness strive to give expression to their own gratitude, love, and admiration. In 1580 he was ransomed by the charity of the Redemptorist Fathers and the devotion of his family, which reduced itself to poverty to provide the sum required; and rejoining his old regiment in Portugal, he served in the expedition to the Azores under the Marquis of Santa Cruz. The story of a liaison with a Portuguese lady is an invention of the biographers to account for a certain Isabel de Saavedra mentioned in an official document of 1605 as his natural daughter. There is no other evidence of her existence, and if this is to be relied upon she was born after his marriage, and nearly two years after his return from Portugal. At the close of the war he retired from military life and turned his attention to literature. His first work was the *Galatea*, a pastoral romance of the same class as the *Diana* of Montemayor and the *Filida* of his friend Montalvo. It was printed at Alcalá in 1585—not, as is commonly said, Madrid, 1584. While it was passing through the press he married, and for two or three years strove to gain a livelihood by writing for the stage. He produced between twenty and thirty plays, of which two only, the *Numancia* and the *Trato de Argel*, have survived; but from his own account it is plain that, though not ill received, they failed to attract, and that he was driven to seek some other employment. In 1587 he migrated to Seville, where he obtained the post of deputy-purveyor to the fleet. In 1594 he was appointed a collector of revenues for the kingdom of Granada; but in 1597, failing to make up the sum due to the treasury, he was sent to prison at Seville. He was released, however, on giving security for the balance, but not reinstated; nor can the government be charged with undue harshness, for though no stain attaches to his integrity, it is clear that as a business-like official he was not faultless. He remained some time longer at Seville, but nothing is known of his movements from 1599 to 1603. Local tradition maintains that he wrote *Don Quixote* in prison at Argamasilla in La Mancha; but it has nothing to support it save the fact that Argamasilla is Don Quixote's village. In 1603 he was living at Valladolid; in September 1604 leave was granted to print the first part of *Don Quixote*, and early in January 1605 the book came out at Madrid. It is commonly asserted that its reception was cold; but the truth is that it leaped into popularity at once. Within a month two pirated editions were in the press at Lisbon; by the autumn five editions had been published; and Don Quixote and Sancho Panza paraded the streets as familiar characters in the pageants at Valladolid that spring. By a minority, however, it was not welcomed. Lope de Vega wrote sneeringly of it and its author months before it was printed—for it had a pre-

vious circulation in manuscript—and he and his brother-dramatists showed how bitterly they resented the criticism in chapter 48. Cervantes was slow in taking advantage of his popularity. Instead of giving his readers the sequel they asked for, he busied himself with writing for the stage and composing short tales, or 'exemplary novels' as he called them. The *Viaje del Parnaso*, a poem of over 3000 lines in *terza rima*, reviewing the poetry and poets of the day, was another of his productions at this time. In 1613 he published his twelve *Novelas*, and promised his readers the second part of *Don Quixote* 'shortly.' But in 1614 a writer, under the pseudonym of Alonso Fernandez de Avellaneda, brought out a spurious second part, with an insulting preface, full of coarse personal abuse of Cervantes. It was the work of a dull plagiarist, an imitator insensible to the merits of his model; but it served as the spur Cervantes needed to urge him to the completion of the genuine second part, which was sent to the press early in 1615, and published at the end of the year. It was not too soon; his health was already failing, and he died at Madrid on the 23d of April 1616. His last labours were given to things more important in his eyes than *Don Quixote*. While it was in the press he revised and published his rejected comedies and interludes, and but a short time before his death he finished his romance of *Persiles and Sigismunda*. There are few pieces of his writing more characteristic of the man than the last two that ever came from his pen—written, indeed, upon his very deathbed—the address to the reader and the dedication to the Conde de Lemos, whose generosity had relieved him from the pressure of poverty; and, like every glimpse of himself that his pages give us, they make us wish that we knew more of one so full of wisdom, patience, and charity, so bright and so brave.

It is in right of *Don Quixote* that the name of Cervantes has a place here; but his minor works entitle him to an honourable one in the history of Spanish literature. His novels are the best of their kind—a kind Spain excelled in; and though the *Galatea* is doubtless inferior to the *Diana*, its greatest fault is that, like the *Diana*, it belongs to a radically insipid species of romance. The title of poet is commonly denied him; but if a good deal of his poetry is weak, there is much that only a poet could have written, and not even Garcilaso had a finer sense of melody or a truer touch in verse. It would be unjust to judge of his dramatic powers by the comedies printed in 1615. They were nothing more than a desperate attempt to gain a footing on the stage by a concession to the popular taste. To found a great national drama worthy of his country was the ambition of his life, and the first step was to obtain a hearing. The tragedy of *Numancia*, with all its defects the most powerful and original drama in the language, is a better measure of Cervantes as a dramatist. And if it is impossible to accept his own estimate of the *Persiles and Sigismunda*, no reader will deny its invention and grace of style. His minor works all show signs of the author's care; *Don Quixote*, on the other hand, is the most carelessly written of all great books. Cervantes, it is plain, did not look upon it in that light. He was very proud of its popularity; but all he ever claims for it is that it will amuse, and that it did the state some service in laughing chivalry romances out of fashion. He wrote it by fits and starts; he neglected it for his other works; he sent it to the printers without revision, and made merry over their blunders and his own oversights. But it may be that we owe more to this carelessness than we think. One of

the marvels of this marvellous book is its perennial youth. After well-nigh three centuries it is as fresh and full of life as when it came from La Cuesta's press. In his other works Cervantes studied recognised models and consulted the tastes of the day; in *Don Quixote* he followed the lead of his own genius alone, and wrote only as instinct prompted him. Written in a desultory fashion, it had time to grow and ripen under his hand; *Don Quixote* and *Sancho*, outlines at first, became by degrees flesh and blood realities to his mind, and beings that he loved; and the book—the second part especially—served him as a kind of commonplace-book to which he turned to when he was in the mood, making it the depository of his thoughts and record of the experience and observation of a stirring life. We need not commit the disloyalty of doubting his word when he says that all he sought was to cure his countrymen of their passion for chivalry romances. He had motive enough in the magnitude of the evil, and his was only one of scores of voices lifted up against it; nor is there anything extraordinary in a champion of true chivalry, as he was, resenting a mockery that made it contemptible. But the genius of Cervantes was essentially discursive, and many other offenders and offences were comprehended in the indictment that he brought against the romances of chivalry and their readers.

The only complete edition of Cervantes' works is that of Rivadeneyra (in 12 vols. large 8vo, Madrid, 1863-64). Editions of the selected works are those of Ibarra (26 vols. small 8vo, Madrid, 1803-5), Bossange (10 vols. 12mo, Paris, 1826), and vol. i. of the *Biblioteca de Autores Españoles* (Madrid, 1846). Of *Don Quixote* in the original about 150 editions are known, and more than double that number of editions in other languages. The first worthy of the book was Tonson's (London, 1738, in 4 vols. 4to); other notable ones are the Academy edition (4 vols. 4to, Madrid 1780); Bowle's (6 vols. 4to, Salisbury and Lond. 1781); Pellicer's (5 vols. 8vo, Madrid, 1797-98); Clemencin's (6 vols. 4to, Madrid, 1833-39), with exhaustive commentary and notes; Hartzenbusch's, in vols. iii.-vi. of the complete works, and also in 4 vols. small 8vo. 1863, a beautiful pocket edition printed at Argamasilla, in the house which was, according to local tradition, the prison of Cervantes; in these last the editor has in many instances restored the text of the first edition, but in many also recklessly tampered with it. F. Lopez Fabra's (2 vols. 4to, Barcelona, 1871-74) is an admirable reproduction by photography of the first edition. The claim of Señor Ortego's edition (Palencia, 1884) to give corrections made by Cervantes himself cannot be seriously maintained. There are translations in fourteen languages. The oldest is the English by Shelton, made in 1608 and printed 1612 (second part, 1620), a vigorous but rude and inaccurate version. Other English translations are those of Phillips (1689), Motteux (1702), Jervas (commonly called Jarvis, 1742), Smollett (1755), A. J. Duffield (3 vols. 8vo, 1881), John Ormsby (4 vols. 8vo, 1885), and H. E. Watts (5 vols. 4to, 1888 *et seq.*). In French there are nine versions, besides abridgments: the oldest is Oudin's (printed in 1616), the best Viardot's (1836). In German there are no less than thirteen, from the earliest in 1621 to the latest and best by Ludwig Braunsfels in 1883-84. There are as many as ten Russian versions, but most of these are from the French, or abridgments. Franciosini's Italian version appeared as early as 1622, and has been followed by two others; and there are versions in Dutch, Danish, Polish, Portuguese, Swedish, Hungarian, Bohemian, Serbian, and Greek. The best Life of Cervantes is by Navarrete; but there is also a good one by D.

Geronimo Moran attached to the édition de luxe of *Don Quixote*, in 3 vols. imp. 4to, Madrid, 1863.

Cervetri (from *Cere Vetus*), a village of Italy, 19 miles WNW. of Rome, on the site of the ancient *Cere* or *Agylle*, formerly one of the most important cities of Etruria. Conquered and degraded by the Romans in 353 B.C., it experienced but a brief renewal of prosperity under the empire as a watering-place (the warm *Bagni del Sasso*, still used), and finally fell into decay in the 13th century. Many Etruscan remains have been found near by.

Cervidae and **Cervus**. See DEER.

Cervin, MONT. See MATTERHORN.

Cesalpino. See CÆSALPINUS.

Cesarewitch. See CZAR.

Cesari, GIUSEPPE (sometimes called ARPINO), an Italian painter, born at Arpino about 1568, was greatly honoured by no less than five popes, and died at Rome, 3d July 1640: His works—in fresco and oil—display lively imagination, and great tact in execution.

Cesarotti, MELCHIORE, an excellent Italian poet, was born 15th May 1730, at Padua, where he filled the Greek and Hebrew chairs. He gained a reputation by his translation of Macpherson's *Ossian* (1763). The versification of this work, like that of his free translation of the *Iliad*, under the title of *La Morte di Ettore*, was admired by Alfieri, and Cesarotti unquestionably threw fresh life into Italian literature. He also wrote on the philosophy of language and of taste. • *Sua Lingue* (8 vols. 1785) and *Ragionamento sulla Filosofia del Gusto* are his best works. He died 3d November 1808.

Cesena, a town of Central Italy, 12 miles SE. of Forlì by rail, with a cathedral and a trade in silk, wine, hemp, and sulphur. Cesena gave birth to two popes—Pius VI. and VII. Pop. (1881) 11,435. Here Murat defeated the Austrians, 30th March 1815.

Cesnola, COUNT LUIGI PALMA DI, archaeologist, was born near Turin, June 29, 1832. He served with the Sardinian contingent in the Crimean war, went to New York in 1860, and served as a volunteer in the civil war. Appointed American consul at Cyprus in 1865, he commenced a series of excavations which he continued for about ten years with the most remarkable success. His splendid collection of statues and figures, lamps, vases, inscriptions, and other antiquities, was opened in New York in 1872 as the 'Cesnola Collection of Cyprian Antiquities.' Doubts expressed in 1879 as to the authenticity of part of the collection were proved to be groundless. His chief work is *Cyprus, its ancient Cities, Tombs, and Temples* (1877).

Céspedes, PABLO DE, Spanish painter, born at Cordova in 1536, studied at Rome under Michael Angelo and Raphael, and in 1577 became a prebendary at Cordova, where he established a school of art, and was also active as an architect, painter, and writer. He died 26th July 1608.

Cess (short for *asses*). See LAND-TAX.

Cessio Bonorum (Lat. 'cession or surrender of goods'), a process which the law of Scotland borrowed from that of Rome, and which also appears in most of the continental systems. On making a surrender of estate to his creditors, the debtor was granted a judicial protection from imprisonment in respect of all debts then due by him. As, however, imprisonment for debt was abolished by the Debtors Act, 1880, except in the case of rates and taxes due, cessio as a process for the protection or liberation from imprisonment of insolvent debtors is now practically obsolete. The Act of 1880, however, introduced a new process of cessio, resembling sequestration, and really a cheap

and summary method of distributing a small estate among the creditors. The petition must be presented in the sheriff-court either by a creditor or by the notour bankrupt himself. Notice is given in the *Gazette*, there is a meeting of creditors, the debtor is publicly examined, the sheriff grants a decree appointing a trustee and ordering the debtor to convey all his estate (except working tools, alimentary funds, and future acquisitions) to the trustee, who then ranks the various claims on the estate, subject to an appeal to the sheriff. A most important change was introduced by the Bankruptcy and Cessio Act, 1881, which provides for the first time that the debtor under a cessio may obtain a statutory discharge, but only if he pays 5s. per £1, or satisfies the sheriff that failure to pay such a dividend is not due to his fault. The process of cessio must be distinguished in some of its effects from the English and American assignment for the benefit of creditors under insolvent statutes. See BANKRUPTCY, INSOLVENCY, SEQUESTRATION; Goudy on *Bankruptcy* (1886).

Cesspool. See SEWAGE.

Cestoid Worms (*Cestoda*), an order of flat worms (Plathelminthes), of internal parasitic habit, and generally known as Tapeworms (q.v.). The adult consists of an asexual 'head,' attached by hooks or suckers or both to the host, and budding off a long chain of flat sexual, hermaphrodite 'joints,' which become mature at a certain distance from the 'head,' have a measure of individuality and independence, and are eventually expelled. There is no alimentary canal nor vascular system; the nervous system is usually complex, but of a low order; there is a well-developed excretory system of branching tubes. The reproductive organs of the 'joints' are usually very complex. The liberated 'joints' or 'proglottides' break up, and set free embryos, which find their way into other hosts, and undergoing considerable change become bladder-worms, develop a head, or in some cases heads, and only become sexual when their host is in turn eaten by the original species in which the tapeworm flourished. There is thus an alternation of generations between the asexual bladder-worm and the sexual tapeworm. The order includes about 25 genera and 500 species, mostly parasitic in vertebrates. The genus *Tania* (tapeworm) includes more than half the known species. The Cestodes are linked to the flukes or Trematodes by forms like *Amphilina*, *Caryophyllæus*, and *Archigetes*, which have no 'joints,' and a single reproductive system; and there is a well-marked series from these up to the most specialised *Tania*. *Echineibothrium*, *Phyllobothrium*, *Anthobothrium*, *Acanthobothrium*, *Tetrarhynchus*, *Ligula* (q.v.), *Bothriocephalus* (q.v.), are the important genera besides *Tania*. See TAPEWORMS; also BLADDER-WORM, PARASITISM, and Leuckart's *Parasites of Man*.

Cestracion, a genus of sharks, regarded as constituting a distinct family, Cestraciontida, although not more than four species are known as now existing. It is characterised by having two dorsal fins and one anal, the first dorsal situated over the space between the pectorals and ventrals; a spine forming the front of each dorsal; a short wide tail, with its upper lobe strongly notched beneath; the mouth at the fore end of the snout; spiracles distinctly visible, rather behind the eyes; and small gill-openings. The front of the mouth is armed with obtuse angular teeth, whilst the margins and inner surface of the jaws are covered with pavement-like teeth, presenting a general continuity of surface, as in skates, and disposed in rounded oblique scrolls—the former evidently adapted to the seizing of food, the latter to the

crushing and bruising of it. They are of obvious use with a diet of hard-shelled crustaceans and

Upper Jaw of Port-Jackson Shark (*Cestracion philippi*).

molluscs. The front teeth are sharp in the young forms. The egg-case has two curious spiral ridges surrounding it. The Port-Jackson Shark, or 'Nurse' (*C. philippi*) of the Australian seas, and the Cat Shark of Japan and China (*C. zebra*), seem to differ chiefly in the patterns of colour. None exceed five feet in length. The Cestraciontidae are particularly interesting to geologists, for the oldest fossil sharks belong in great part to this family. 'The remains are found even in the Palaeozoic strata; they become more numerous in the Carboniferous series; they are very numerous in the Lias and Chalk formations; but there they cease almost entirely, the strata of the Tertiary series containing scarcely any of them.' In modern times the species are reduced, as we have

seen, to four at most, and other types of shark have become more prevalent. The fossil forms were abundant, also much larger, and the cestracions thus furnish a particularly good illustration of a decadent family.

Cestui que Trust, a person for whom another is a trustee. The term is Norman-French, and means in English law, and also in the United States, exactly what Beneficiary (q.v.) means in Scots law.

Cestus (Gr. *kestos*, 'embroidered'), a girdle worn by Greek and Roman women, but at what part of the body is somewhat uncertain. It was worn apparently between the *cingulum*, which was a sash or girdle over the tunic just under the bosom, and the *zone*, worn mostly by young unmarried women lower down the body, just above the hips. According to Winckelmann, the cestus was itself worn round the loins; according to Heyne and Visconti, immediately under the bosom. The cestus of Aphrodite was covered with such alluring representations of the joys of love that she who wore it was irresistible. It was borrowed by Hera when she desired to win the love of Zeus. —CESTUS, or more correctly, CÆSTUS, the boxing gauntlets worn by the ancient prize-fighters, which consisted of leather thongs bound round the hands and wrists. They sometimes reached as high up as the elbows, and were armed with lead or metal bosses to increase the force of the blow.

Cetacea, an order of mammals, of aquatic habit and fish-like form. The head is large, the

neck indistinct; there is generally a median dorsal fin, and the tail has lateral flukes; the fore-limbs are reduced to paddles, the hind-limbs are at most represented by slight internal traces; the skin is smooth, and, with the occasional exception of a few bristles near the mouth, hairless; there is a thick layer of fat or blubber under the skin which serves instead of hair as a heat-retainer. The eye is small, there is no external ear; the nostrils are situated vertically. The bones are spongy and oily, the neck vertebrae are compressed and often fused, there is no union to form a sacrum. The skull is peculiarly modified, the brain-case being high, and the front part prolonged into more or less of a snout. There are no collar-bones; the bones of the arm are flattened and stiff; the joints of the second and third fingers are always above the normal number; the whole arm forms a flipper; the hip-girdle and hind-leg are degenerate. In one group teeth are absent except in the fetus, and are replaced by 'whalebone' growths from the palate; in no case is there more than one set of teeth. The stomach has several chambers; the intestine is simple. The liver is less divided than usual, and there is no gall-bladder. The blood-vessels form wonderful networks (*retia mirabilia*). The top of the windpipe is prolonged forwards so as to form, when embraced by the soft palate, a continuous air-passage from nostrils to lungs. The brain is large. The placenta is 'non-deciduate and diffuse.' The teats are two in number, and lie beside the female genital aperture; the milk is squeezed into the mouth of the sucking young.

The Cetacea are widely distributed in all seas and in some large rivers. They swim powerfully, and the tail works up and down, not sideways. They rise to the surface to breathe, and do not spout sea-water from their blowholes. The expiration is periodic and violent, and the forcibly expelled air being laden with water, vapour may condense in a pillar of fine spray, or the ascending column may carry up some surface sea-water along with it, but it must be recognised that the process is simply that of ordinary expiration in peculiar conditions. They are mostly inoffensive, generally social in habit, vary from 4 to 60 feet in length, and feed on jelly-fish, crustaceans, pteropods, cuttlefish, fishes, and in one genus (*Orca*) on seals and on other whales.

Two very distinct series have to be distinguished —(a) the Toothed Whales or Odontoceti, and (b) the Baleen Whales or Mysticoceti. The former include Sperm Whales (*Physeter*), the Bottlenose (*Hyperoodon*), the genus *Platanista* and its allies, and the great family of Dolphins (q.v.). The latter sub-order includes the Right Whale (*Balæna*), the 'Humpbacks' (*Megaptera*), and the Rorquals (*Balenoptera*).

In the Eocene, Cetacea are represented by primitive, less specialised forms, known as Zeuglodon, but the remains are, as one would expect, somewhat fragmentary, and the conclusions to be drawn from them very uncertain. In Miocene and Pliocene strata still more fragmentary cetacean remains have been found, and are grouped together in the genus *Squalodon*.

There is much doubt and dispute in regard to the origin and affinities of Cetacea. They are related by some to Carnivores, but the researches of Professor Flower have made it more probable that they have much closer affinities with Ungulates. He regards it as not unlikely that the whole group had a fresh-water origin. Fuller details must be sought under the article WHALE. See Flower's article 'Mammalia,' *Ency. Brit.*

Ceteosaurus (*kētos*, 'whale,' *sauros*, 'lizard'), a large dinosaurian reptile belonging to the Jurassic System (q.v.). According to Professor

Phillips, it may have reached a length of 50 feet, and when 'standing at ease' was probably not less than 10 feet in height and of a bulk in proportion. It appears to have frequented the marshes and river-sides of the period, and to have been a vegetable-feeder. The word is also spelt *Cetiosaurus*.

• **Cetewayo.** See ZULUS.

Cetinje (also spelt *Cettigné*), capital of Montenegro, lies in a rocky valley 2093 feet above sea-level, and 17 miles E. of Cattaro, with which it is connected by a carriage road. It is the residence of the prince, and of an archimandrite, and consists of an unpretentious palace, a few private houses, an abbey, gaol, arsenal, theatre (which serves also for the state library and national museum), hospital, theological seminary, gymnasium, and a girl's high-school, maintained at the charge of the Empress of Russia. Behind the palace is an elm, under which the prince delivers judgments. Pop. 1200.

Cetotolithes, a name given by Owen to fossil cetacean ear-bones, which occur in great abundance in the Red Crag of Suffolk (see *PLIOCENE*). They are rubbed and water-worn, and have evidently been washed out of some earlier strata, which remain yet unrecognised. The extent of these earlier strata must have been very great, seeing that the crag beds now extend over a large district in Essex and Suffolk, and attain a thickness in some places of not less than 40 feet. Professor Henslow in 1843 drew the attention of agricultural chemists to this deposit as a source of materials for manure, and since then superphosphate manures have been manufactured from it to the value of many thousand pounds annually; a striking example of the valuable practical results which frequently flow from a purely scientific discovery.

Cette, an important seaport town of France, in the department of Hérault, is built on a neck of land between the lagoon of Thau and the Mediterranean, 23 miles SW. of Montpellier. The space inclosed by the piers and breakwater forming the harbour can accommodate about 400 vessels; and the harbour is defended by forts. A broad deep canal, lined with excellent quays, connects the port with the Lake of Thau, and so with the Canal du Midi and the Rhone, thus giving to Cette an extensive inland traffic; it has likewise an active foreign commerce. The principal trade is in wine, brandy, salt, dried fruits, fish, dyestuffs, perfumery, and verdigris. Cette has shipbuilding yards, salt-works, glass-works, factories for the manufacture of syrups and grape-sugar, &c. It is a resort for sea-bathing, and has extensive fisheries. Colbert founded it in 1666. Pop. (1872) 25,181; (1886) 36,762.

Ce'uta, a fortified port belonging to Spain, on the coast of Morocco, opposite Gibraltar. The town occupies the site of the Roman colony of *Ad Septem Frutres*, so called from the seven hills rising here in a group, of which the most prominent are Montes Almina and Hacho; on the latter, the ancient *Abyla* (one of the Pillars of Hercules), is a strong fort, and on the former, among beautiful gardens, lies the New Town. Ceuta contains a cathedral, a hospital, and convents, but is chiefly of importance as a military and convict station. The harbour is small, and exposed to the north, but has a lighthouse and some small trade. The mixed population number about 9700. The place was a flourishing mart under the Arabs, who corrupted its Roman name to *Sehtah*; there the first paper manufactory in the Western world is said to have been established by an Arab who had brought the industry from China. In 1415 it was captured by the Portuguese, and annexed to Portugal; it fell to Spain in 1580. It has resisted

several sieges by the Moors (1694-1720 and 1732), and is still the most important of the four African *Presidios* (q.v.).

Cevadilla. See SABADILLA.

Cévennes (ancient *Cebenna*), the chief mountain-range in the south of France. With its continuations and offsets, it forms the watershed between the river-systems of the Rhone and the Loire and Garonne. Its general direction is from north-east, to south-west, commencing at the southern extremity of the Lyonnais Mountains, and extending under different local names as far as the Canal du Midi, which divides it from the northern slopes of the Pyrenees. The Cévennes extend for over 150 miles, through or into nine departments. The central mass lying in Lozère and Ardèche, where Mont Lozère attains 5584 feet, and Mont Mézenc (the culminating point of the chain) 5754 feet. The average height is from 3000 to 4000 feet. The mountains consist chiefly of primary rocks, covered with tertiary formations, which in many places are interrupted by volcanic rocks. For the religious wars of which the Cévennes have been the arena, see ALBIGENSES, CAMISARDS, WALDENSES; and for a vivid description of the scenery and the peasantry, Mr R. L. Stevenson's *Travels with a Donkey in the Cévennes* (1879).

Ceylanite. See SPINEL.

Ceylon (the *Taprobane* of the Greeks and Romans, and the *Sevondib* of the *Arabian Nights*), an island and British crown colony in the Indian Ocean, to the south-east of India, from which it is

separated by the Gulf of Mannar and Palk Strait, 32 to 120 miles broad. It lies between 5° 55' and 9° 51' N. lat., and 79° 42' and 81° 55' E. long.

Extreme length from north to south, from Point Palmyra to Dondera Head, 266 miles; greatest width, from Colombo to Sangemankande, 140 miles. Area, 24,702 sq. m., of which more than one-fifth is under cultivation.

Physical Features.—In natural scenery Ceylon can vie with any part of the world; and as it rises from the ocean, clothed with the rich luxuriance of a tropical vegetation, it seems to the voyager like some enchanted island of Eastern story. Its hills, 'draped with forests of perennial green,' tower grandly from height to height, till they are lost in clouds and mist. Near at hand, a sea of sapphire blue dashes against the battlemented rocks that occur at isolated points, and the yellow strands are shaded by groves of noble palms. In shape Ceylon resembles a pear, but its inhabitants more poetically compare it to one of their elongated pearls. Undulating plains cover about four parts of the island, and the fifth is occupied by the mountain-zone of the central south, which has an elevation of from 6000 to 8000 feet above the sea-level. Pedrotallagalla, the highest mountain in the range, attains the height of 8260 feet; the celebrated mountain of Adam's Peak, 7420 feet; and the tableland of Nuwara-Eliya, 6210 feet.

Geology.—The mountain-system is mainly composed of metamorphic rocks, chiefly gneiss, frequently broken up by intrusive granite. With the exception of some local beds of dolomitic limestone, the gneiss is everywhere the surface rock, and the soil is composed of its disintegrated materials. The northern part of the island is rising; and the immense masses of corals continually increasing, retain the debris brought from the Indian continent by the currents of the sea, and thus form a flat, ever-increasing madrepora plain.

Metals and Precious Stones.—Iron can be obtained in great quantities, and anthracite and rich veins of plumbago exist on the southern range of hills. Gold has recently been found. The *gems* of Ceylon have been celebrated from time immemorial. Sapphires, rubies, the oriental topaz, garnets, amethysts, cinnamon stone, and cat's-eye are the principal gems and precious stones of the island. The declared value of the precious stones exported is about £10,000 annually; but as large numbers are purchased by passengers calling at Colombo and by native merchants for sale in Southern India, the actual value is doubtless very far in excess of the sum named. The pearl-fisheries of Ceylon were known at a very remote date in the commercial history of the world. Under the Portuguese and Dutch governments, and now under the British government, the pearl-fisheries form a monopoly, and are under the inspection of an officer, who reports when a sufficient number of pearl-yielding oysters have reached maturity, and when the prospect of a successful fishing is thus probable. The fishings are intermittent and occur at irregular dates. In 1863 the value of pearls obtained was £56,000; in 1874, it was £10,000; in 1877, £19,000; in 1879-80, £29,500; in 1881, £59,800; in 1887, £39,000; and in the intermediate periods between these dates there was practically no fishing at all.

Rivers.—The most important river in Ceylon is the Mahavila-ganga. It has its source in the vicinity of Adam's Peak, and after draining more than 4000 sq. m., it separates into several branches, and enters the ocean near Trincomalee. The south side of the island is watered by ten rivers of considerable size.

Harbours.—Galle, at the southern extremity of Ceylon, and Trincomalee on the eastern coast, are the only natural harbours capable of containing ships of large draught. The construction of a breakwater at Colombo, the capital of the island,

which provides safe anchorage for ships of any size in all weather, has concentrated the commerce of the island there, and has also attracted from Galle the mail and passenger steamers from Europe, India, Australia, and China, which used to coal and tranship at Galle. At Trincomalee are the naval stores and dockyard, and the harbour is the finest in eastern waters.

In *climate*, Ceylon has a great advantage over the mainland of India, and as an island enjoys a more equable temperature. The average for the year in Colombo (q.v.) is 80° in ordinary seasons. April is the hottest month; and in May the south-west monsoon commences amid a deluge of rain, and continues the prevailing wind till October, when the north-east monsoon sets in: 80 inches is the average annual fall of rain, though in an exceptional year 120 inches have been registered. The beautiful tableland of Nuwara-Eliya was first visited by Europeans in 1826, and is now used as a sanatorium. Here the thermometer in the shade never rises above 70°, while the average is 62°; the nights are cool and refreshing. The north of the island, including the peninsula of Jaffna, the plains of Nuwara-Kalawa, and the Wanny, may be reckoned as a third climatic division. Here the annual fall of rain does not exceed 30 inches, and irrigation is largely employed in agriculture.

Flora.—The general botanical features of Ceylon are in many respects similar to those of Southern India. A very large number of the species of plants is, however, peculiar to the island. About 800 species (nearly 30 per cent. of the whole number found in Ceylon) are endemic—that is, found nowhere else in the world. The tree-vegetation of the forests is almost wholly composed of such endemic species, and not a few of endemic genera. The affinities and near alliances of these are with the plants of the Malay Islands and Peninsula. Hence, to speak more correctly, the flora of Ceylon partakes of an Indian as well as a Malayan character, but is identical with neither. As may be expected from the climatic peculiarities of the country the flora is greatly diversified. In the south-west mountainous parts of the island, with the exception of some grassy tracts called *patanas* and the plantations of tea, coffee, and cinchona, the slopes and summits are forest-clad. The trees are ever-green, with thick coriaceous leaves, growing closely together and forming dark jungles. The undergrowth is largely made up of gregarious plants known as *Nila*, species of the genus *Strobilanthes*, which only flower at regular intervals of five, six, or seven years. Tree-ferns, often 25 feet in height, scarlet-flowering rhododendrons, numerous tufted bamboos, melastomads, and orchids are found in mountain forests. In the low country the vegetation is marked by the prevalence of palms, the cocoa-nut being pre-eminent. The beautiful areca-palm, the feathery jaggery or kitul, and the lordly talipot are the glories of Ceylon lowland vegetation. In the recesses of low-country forests the trees are high and closely packed. Amongst the timber-trees the most valuable are the calamander, satin-wood, and ebony. Two very interesting and peculiarly slender tree-ferns grow in the hot steamy forests of Ceylon, as also the most admired of Ceylon orchids, *Dendrobium Maccarthiae*. There has been extensive cutting down of forest in the mountains of Ceylon to establish plantations, and the lowlands have suffered no less severely by the indolent and improvident practice of native cultivation. As a consequence numerous foreign weeds, such as the lantana, white weed, and Spanish needle, have established themselves to the exclusion of native vegetation in the hills; while in the lowlands coarse grasses and worthless scrub have

covered the country. The orchids of Ceylon number about 150 species. With the exception of about a dozen *Dendrobiums*, *Erias*, and *Saccolabiums*, and the lovely *Wana-rajah*, there are few of a striking character. The ferns number about 270 species. Among the latter is an anomalous variety which bears spores on the upper instead of on the under side of the frond. One of the handsomest native trees of Ceylon is the Muruta (*Lagerstræmia Flos-regine*). To this might be added the *Saraca indica*, and the lovely Na' (*Mesua ferrea*), or ironwood. In the forests climbing-plants and epiphytes of prodigious size and striking appearance cover the trees with a mass of parasitical foliage of extraordinary growth. In the north of Ceylon the dry forest-region is remarkable for its valuable timber-trees, such as the Palu, Halmilla or Trincomalee wood, and ebony. The characteristic palm of the north and of the peninsula of Jaffna is the Palmyra (*Boruss flabelliformis*).

Fauna.—In Ceylon, quadrumanous animals are represented by the *Loris gracilis* and five species of monkeys. Sixteen species of bats exist in Ceylon, including the flying-fox. Of the larger carnivora, the bear and leopard; and of the smaller, the palm-cat and the glossy genetie (the civet of Europeans) may be mentioned. The tiger is not met with in Ceylon. Deer, buffaloes, and the humped ox of India are plentiful; the little musk-deer is less than 2 feet in length. The elephant, which is for the most part tuskless, is emphatically lord of the forests of Ceylon. The wild boar is also found. Whales are captured off the coast. Three hundred and twenty species of birds are found. The song of the robin and long-tailed thrush, and the flute-like voice of the oriole, are heard over the whole mountain-zone and far down into the neighbouring plains. Eagles, the beautiful peregrine falcon, owls, swallows, kingfishers, sun-birds, bulbuls, crows, parrots, pigeons, pea-fowl, jungle-fowl, and many others of the feathered tribe, might be mentioned did space permit. Myriads of aquatic birds and waders, amongst which the flamingo is conspicuous, cover the lakes and lagoons. The crocodile is the largest reptile in the island; tortoises and lizards are also found. There are a few species of venomous snakes, and of these the tipolonga and the cobra da capello are the most deadly.

Inhabitants.—The Singhalese (*Sinhalese*, also spelt *Cingalese*), the most numerous of the natives of Ceylon, are supposed to be the descendants of those colonists from the valley of the Ganges who first settled in the island 543 B.C., and speak an Aryan language closely allied to the Pali (q.v.). The dress of the men, who have delicate features and slender limbs, looks singularly effeminate, and consists of a *comboy* or waist-cloth, very much resembling a petticoat; their long hair, turned back from the forehead, is confined with combs, and earrings are worn by way of ornament. Polyandry still lingers in the interior of Ceylon; but this and many other customs repugnant to Christianity are disappearing under the influence of education, of which the Singhalese readily avail themselves. The Kandyans, or Highlanders, are a more sturdy race, and maintained their independence for three centuries after the conquest of the low country by European settlers. The Malabars, or Tamils, have sprung from those early invaders of Ceylon who from time to time swept across from Southern Hindustan, and contended with the Singhalese kings for the sovereignty of the island. They have formed the chief population of Jaffna for full 2000 years, and constitutionally excel the Singhalese and Kandyans. The Moormen, who are the most energetic and intelligent

of the native communities, are met with in every province as enterprising traders, and are generally believed to be of Arab descent. The 'burghers' of Ceylon are people of European descent, who have become naturalised. Those of Portuguese extraction hold the lowest place, and are mostly tradesmen and artisans; but the Dutch burghers frequently fill responsible posts, and are employed in the government offices. There is besides a remarkable tribe of outcasts—the Veddahs—hardly removed from the wild animals of the forest, and believed to be descended from the Yakkhos, the aboriginal inhabitants of the country. They occupy a district in the eastern part of the island, and have there preserved their ancient customs and manner of living unaltered for more than 2000 years.

Religion.—The Singhalese are devoted to Buddhism (q.v.), which is the prevailing religion of the island. Its sacred books are identical with those of Burma and Siam, and both record the doctrines of Gautama in the Pali language; the deviations are in matters of practice. The Malabar kings adulterated Buddhism to a considerable extent with Brahmanism, introducing the worship of Hindu deities into the Buddhist temples, and this continues more or less to be the case. More than once have the Buddhists of Ceylon sought to restore the purity of their faith—at one time sending deputies to Siam, at another to Burma, with this object in view. The Burman or Amarapura sect have long been the reformers of Singhalese Buddhism, and maintain no very friendly relations with the party who, supported by the priests of Siam, sanction the worship of Hindu deities and the employment of the priesthood in secular occupations, uphold caste, and restrict the sacred books. Caste was acknowledged by the Singhalese prior to the introduction of Buddhism, which in principle is opposed to it; but so firmly was it rooted that it still endures, though more as a social than a sacred institution. Gautama Buddha is said to have visited Ceylon three different times to preach his doctrine, and his *Sri-pada*, or sacred footstep, on the summit of Adam's Peak (q.v.), still commands the homage of the faithful. Buddhism was not, however, permanently introduced into Ceylon till 307 B.C. The influence of the priests gradually increased, and, by the piety of the Singhalese kings, monasteries were richly endowed, and at the present day no less than one-third of the cultivated land of the island is computed to belong to the priesthood, and is exempt from taxation. The priests of Ceylon are divided into two orders; any member is at liberty to lay aside his ascetic character, and return to a secular life. The most celebrated Buddhist relic in Ceylon is the *Dabada*, or sacred tooth of Gautama, at Kandy, which is guarded with jealous care, and preserved in an elegant shrine; but it is well known that the original relic was destroyed by the Portuguese, and the present substitute is a piece of discoloured ivory, bearing no resemblance to a human tooth. Brahmanism or Hinduism (q.v.) is the faith of the Tamils or Malabars, but the Moormen are Mohammedans. After the expulsion of the Dutch Christians, Protestant missions to the natives of Ceylon were commenced by the Baptists in 1813. The Wesleyan Methodists followed in 1814, the Americans in 1816, the Church of England in 1818, and Christian instruction has made some progress amongst the native populations. Schools, collegiate institutions, and female seminaries, under the direction of the missionaries, are in successful operation; and there is a government system of education.

Ancient Buildings.—In all Buddhist countries the sacred buildings present, with certain modifica-

tions, the same general character (see articles **BUDDHISM**, **BURMA**, &c.); and in Ceylon we find the three classes represented by the dagoba, or relic-shrine, the temple proper, and the vihara or monastery. The labour bestowed on these edifices in the early ages of the Singhalese monarchy is truly astonishing. In the north of the island, ruined cities buried for ages in the depths of the forest have been discovered, revealing monuments that in dimensions may almost compare with the pyramids of Egypt. The most remarkable of these vestiges of an early civilisation is Pollanarua, the ancient capital of Ceylon; and here is the celebrated *Gal-wihara*, a rock-hewn temple.

Entrance to the Temple of Dambula.

The cave-temple of Dambula was built 100 B.C., and is the most celebrated in the island. The bell-shaped tapering dagobas of Ceylon, as relic-shrines, answer to the pagodas of Burma—which they very much resemble—and the topes of Afghanistan. The ruins of the Jayawanarama dagoba still reach the height of 249 feet; its diameter is 360 feet; and from base to pinnacle

The Ambustella Dagoba, Mihintala.

it is covered with trees of the largest size. The Ambustella of Mihintala is another remarkable dagoba. A very famous object in connection with Buddhism in Ceylon is the sacred Bo-tree (q.v.) of Anuradhapura. Amongst the antiquities of Ceylon must be mentioned those wonderful monuments of the former greatness of the Singhalese

people—the ruined tanks, with which scarcely anything of a similar kind, whether ancient or modern, can be compared. Thirty colossal reservoirs, and about 700 smaller tanks, still exist, though for the most part in ruins. The restoration of these magnificent works of irrigation has been for some time carried on by the government. In February 1888 the largest and most important tank in Ceylon, that of Kalawewa, was, after four years of labour, completely restored. It was built 460 A.D. to supply Anuradhapura with water, but has been ruinous for centuries. Now again it contains an area of seven square miles of water 20 feet deep, and supplies smaller tanks more than 50 miles distant.

The history of Ceylon may be conveniently divided into ancient and modern, and the latter into the Portuguese, Dutch, and British periods. The most famous of the Singhalese books is the *Mahāvamsa*, a metrical chronicle in the Pali language, extending from the earliest period to 432 A.D., and continued to 1756. The story begins with the invasion of Wijayo (543 B.C.), son of a petty Indian sovereign in the country watered by the Ganges. He subdued the Yakkhos, the aboriginal inhabitants; founded a dynasty that held undivided sovereignty in Ceylon for nearly eight centuries; and bestowed on his kingdom his patrimonial name of Sihala (whence Singhalese, Ceylon). In the reign of King Devenipatiassa (307 B.C.), Buddhism was established as the national religion, and his reign was further remarkable by the planting of the sacred Bo-tree, 288 B.C.; and now commenced the erection of those stupendous buildings already noticed. The next important epoch in Singhalese history is the usurpation of the Malabars (237 B.C.), foreign mercenaries from the Coromandel coast, to whom the native sovereigns had intrusted the defence of the island. In 1071 A.D. a native dynasty was re-established in the person of Wijayo Bahu, which, for 100 years, delivered the country from the dominion of the Malabars. Prakrama Bahu commenced a reign in 1153, the most renowned in the records of Ceylon. He devoted himself to religion and agriculture, and besides many notable religious edifices, he caused no less than 1470 tanks to be constructed, subsequently known as the 'seas of Prakrama.' Thirty years after the death of this monarch, the Malabars landed with a large army, and speedily conquered the whole island. In 1235 a native dynasty recovered a part of the kingdom. During the reign of Dharma Prakrama IX. the Portuguese first visited Ceylon (1505); but it was in 1517 that they first formed a permanent settlement at Colombo for trading purposes. Their encroachments soon met with fierce resistance from the patriotic Kandians. 'Amity, commerce, and religion,' was the Portuguese motto; but their rule in Ceylon is a sad story of rapacity, bigotry, and cruelty. They were at last driven from the island by the Dutch in 1658, after a contest of twenty years, when the fanatical zeal of Roman Catholic sovereigns for the propagation of the faith was replaced by the earnest toil of the Dutch traders to intrench their trading monopolies. But the purely military tenure of the Dutch was destined to give place to the colonisation of the British. It was during the great European war succeeding the French Revolution that the English gained possession of the island. On the 1st August 1795 an expedition under Colonel James Stuart landed at Trincomalee, which was speedily captured, and finally the garrison of Colombo surrendered on the 16th February 1796. By this capitulation, all the Dutch settlements and strongholds in Ceylon were ceded to the English; though the island was not formally annexed to the British crown till the Peace of Amiens,

27th March 1802. The native sovereigns, however, continued in the possession of their mountain territory; but at length the Kandyan king, Wikrama Raja Singha, after perpetrating the most frightful atrocities on his own people, seized and murdered certain native merchants, British subjects, trading to Kandy. War followed, January 1815; Kandy was taken, and the tyrant sent a captive to the fortress of Vellore. On the 2d March 1815, a treaty was concluded with the native chiefs, by which the king was formally deposed, and his territories annexed to the British crown.

After the settlement of the Kandyan provinces, attention was drawn to the hill country of Ceylon as a probable field for the profitable investment of British capital and energy, and among other agricultural enterprises the cultivation of coffee was entered upon. The condition of soil and climate proved favourable, and the abolition of slavery in the West Indies, and the consequent labour difficulties, caused a rush towards Ceylon, and the area under coffee cultivation rapidly extended. The enterprise, though subject to all the vicissitudes incidental to tropical agriculture, steadily grew, and coffee soon became the staple export from the island; and the revenue directly and indirectly derived from it enabled successive governors to bridge rivers, to make roads and railways, and to restore many of the ancient irrigation works which, in the period antecedent to British rule, had fallen into disrepair. In 1869, however, a fungus (*Hemileia vastatrix*) attacked the leaves of the coffee-trees, and the energy of the tree which had hitherto produced fruit was now required for the constant reproduction of leaf. Everything which practice or science could suggest was tried to mitigate or overcome the pest, but in spite of all efforts it steadily increased in virulence, and the coffee-planters were obliged to turn their attention to other products of the soil.

Cinchona, cacao, cardamoms, and many other products were introduced with varying success, but it soon became plain that Ceylon was capable of becoming a great tea-producing country, and tea has become the chief factor in restoring the financial equilibrium.

Cinnamon and cocoa-nut cultivation are chiefly in the hands of natives; tea, cinchona, cacao, and cardamom cultivation in the hands of Europeans; and the export table shows how through the energy of the planters new products have to a great extent replaced coffee.

	Coffee. cwt.	Cinchona Berk. lb.	Tea. lb.
Year ending 30th Sept. 1873	995,493		
" " " 1878	920,292	173,497	3,515
" " " 1883	260,053	6,925,950	1,522,882
" " " 1887	180,429	14,389,134	12,013,886

Between 1883 and 1887 the export of cacao rose from 3588 to 16,638 lb., and of cardamoms from 21,655 to 321,560 lb. Between 1873 and 1887 the export of cinnamon rose from 1,265,757 to 2,299,844 lb. Between 1873 and 1883, that of cocoa-nut oil, from 163,274 to 306,209 cwt.; of coir yarn from 56,921 to 98,697 cwt.; of plumbago from 168,627 to 279,057 cwt.; while that of ebony fell from 46,635 to 18,273 cwt. Minor exports are oils, fibres, and dyes.

Ceylon is the largest and most important of what are known as the crown colonies of the British empire. The government is administered by a governor aided by executive and legislative councils (the former consisting of five members, the latter of fifteen, partially elective), and municipal councils. Local boards and village tribunals give a measure of self-government to the people. The population of Ceylon, 2,763,984 at the census of 1881, has risen to about 3,000,000, of whom

2,000,000 are Singhalese, 750,000 Tamil immigrants and settlers, 200,000 Moormen (Mohammedans of Arab descent), 5500 Europeans, 20,000 Eurasian descendants of Portuguese and Dutch, 2500 Veddahs, 22,000 mixed races.

The revenue, which in 1882 was 12,161,570 rupees, was in 1888, 12,682,548 rupees; but owing to the depreciation of the rupee, the value in pounds sterling was £1,140,147 in 1882, and £1,004,035 in 1886. The total annual trade is about £10,000,000. There are 2500 miles of metalled roads; 185 miles of railways; and 120,000 scholars in the government schools, and those of the various religious denominations. See *Ceylon*, by Sir James Emerson Tennent (2 vols. 1859); Captain Suckling's *Ceylon* (2 vols. 1876); *The Colonial Office List* for the current year; *Ceylon in the Jubilee Year*, by John Ferguson (1887).

Ceyx. See KINGFISHER.

Cezimbra, a coast town of Portugal, about 18 miles S. of Lisbon. Pop. 6815.

Chabas, FRANÇOIS, a great French Egyptologist, was born January 2, 1817, at Briançon. Though at first engaged in commerce, he found time to become a learned linguist, but it was not till 1851 that he gave himself up to the study of hieroglyphics. The first results of his studies appeared in 1856, followed by a series of invaluable books and papers, elucidative chiefly of two important periods of ancient Egyptian history—the conquest of the country by the Hyksos, and the time of their expulsion. Among the more important of his many books are—*Les Pasteurs en Égypte* (1868), *Histoire de la XIX. Dynastie et spécialement des Temps de l'Exode* (1873), and *Études sur l'Antiquité historique d'après les Sources égyptiennes* (2d ed. 1873). From 1873 to 1877 he edited *L'Égyptologie*. He died at Versailles, May 17, 1882.

Chabasite. See ZEOLITE.

Chablis, a town in the French department of Yonne, 12 miles E. of Auxerre. It gives name to an esteemed white Burgundy (q.v.) wine. Pop. 2363.

Chaco, EL GRAN. See GRAN CHACO.

Chaconne (Fr.), an obsolete dance, probably Spanish (*charona*, from Basque *chocuna*, 'pretty'). The movement is slow, and the music, a series of variations on a ground bass, mostly eight bars in length, appears in sonatas as well as in ballets.

Chad, LAKE. See TSAD.

Chad, St (*Ceadda*), was born in Northumbria, became a pupil of St Aidan, spent part of his youth in Ireland, and in 666 became Bishop of York. Doubt having been cast on the validity of his consecration, he withdrew in 669, but was immediately made Bishop of Mercia, fixing the see at Lichfield (q.v.). He died in 672, after a life eminent for humility and sanctity.

Chadwick, EDWIN, C.B., a social reformer, born in the vicinity of Manchester, 24th January 1801, studied law, and was called to the bar in 1830. He attracted the notice of Jeremy Bentham by an article on Life Assurances. He early devoted his attention to questions of social, sanitary, and political science, and was by Lord Grey's government appointed an assistant-commissioner to inquire into the operation of the poor-laws. His report, published in 1833, commanded great attention, and laid the foundation of the later systems of government inspection. On the organisation of the new Poor-law Board, Chadwick was appointed secretary. In connection with this Board, and the General Board of Health, Chadwick for twenty years was energetic in improving the administration of poor-law funds and the sanitary condition of the country. His report on interments in towns (1843) laid the

foundation of later legislation on the subject. He served on commissions as to the employment of children in factories, on preventable diseases, and on education. On a change being made in the Board of Health in 1854, Chadwick retired with a pension. He afterwards took great interest in promoting competitive examinations for government offices, and indeed in almost all questions of social economy. He was an active member of the Social Science Association. Some of his papers appear in the Transactions of the Statistical Society and of the British Association. See *Chadwick's Work and Works on Health and Social Reform*, by Richardson (2 vols. 1885).

Chæronea, a town in ancient Boeotia, near the river Cephissus, memorable for the disastrous defeat of the Athenians here by Philip of Macedon, 338 B.C. This defeat struck a death-blow to the liberties of Greece, and broke the heart of Isocrates; it was the 'dishonest victory' that 'killed with report that old man eloquent.' A colossal marble lion, together with the bones of 260 Greeks, was dug up here in 1880. Here also Sulla defeated the generals of Mithridates in 86 B.C. The famous Plutarch was a native of Chæronea.

Chætoderma, a remarkable primitive gastropod, which in some respects serves as a connecting link between the worm and snail type. See CHITON.

Chatodon, a typical genus of a family of bony fishes, known as Squamipennes. The body is much compressed sideways, and consequently high; the scales are more or less smooth, and cover portions of the dorsal and anal fins in such a fashion that the boundary between fins and body is indistinct.

Chatodon setifer.

The mouth is generally small in front of the snout, and the slender teeth are arranged in bands. The lower rays of the pectoral fins are branched, and the hind fins are situated far forward on the thorax. The Squamipennes, or as some would call them, the Chatodontidae, are tropical fishes, abounding near coral reefs, and well suited in the beauty of their colouring to such brilliant surroundings. They feed on small animals, are never very large, and but little used for food. Chatodon itself is a large genus, with some 70 beautiful species from the tropical Atlantic and Indo-Pacific. It has one dorsal fin, and a moderately long snout. In Chelmo the snout is longer, and is used to draw animals from their crevices. It often gets false credit for catching insects by spouting water. Heniochus is another pretty genus with horns on its head. Holacanthus, one species of which is called the 'Emperor of Japan' by the Dutch, is yet more brilliantly adorned, and Pomacanthus is peculiarly variable in its colouring. The Atlantic species of Ehippus (*E. fuber*) is peculiar in the pathological-like enlargement of some of the bones at the back of the head. The Archer-fish (q.v.) is an allied genus. See Günther, *Study of Fishes* (1880).

Chætopods (Gr., 'bristle-footed'), a class of worms including familiar types like the Earthworm, the Fisherman's Lobworm, and the Sea-mouse. They are often included under the title of Annelids or ringed worms. The body consists of numerous more or less similar joints; and the locomotor organs are furnished with or represented by bristles. The class is split into two main orders of Oligochaeta and Polychæta, of which the latter is much the larger. The Oligochaeta have very rudimentary locomotor structures, which are in fact reduced to bristles; they are fresh-water or subterranean in habit; the familiar earthworm (*Lumbricus*) and certain river and pond worms (e.g. *Tubifex* and *Nais*) are common representatives. The Polychæta are, with three or four exceptions, marine; the bristles, which are numerous, are fixed in special locomotor outgrowths; and many other characters, such as the possession of antennæ, gills, &c., distinguish them from the earthworm order, and are in obvious association with their very different habits. Many of them, described as errant, lead a free life, and are carnivorous in their diet. The common Nereis, or Alitta, and the Sea-mouse (Aphrodite) are good examples. A large number, however, are sedentary in habit, vegetarian in diet, and often inhabit tubes. The lobworm (*Arenicola*), the common Serpula, and Terebella are characteristic types. To the two main orders of Chætopods above mentioned, the parasitic Myzostomata causing 'galls' on feather-stars (Crinoids), and the primitive aberrant Saccocirrus must be added. Polygordius is another common marine worm which, along with a few others, is usually regarded as a survival of the ancestral Chætopods or Annelids. See EARTH-WORM, LOBWORM, SEA-MOUSE, WORMS, &c.

Chafer, a common name for beetles or coleopterous insects, especially for those which, either in the perfect or larval state, are destructive of plants, particularly of the wood, bark, or roots of trees. The word is seldom used alone, but generally as part of a name, with some prefix; thus, we have *Cock-chafer*, *Rose-chafer*, *Bark-chafer*, &c. *Käfer* is the German word for 'beetle.'

Chaffinch (*Fringilla caelebs*), one of the commonest British birds, a species of Finch (q.v.), and probably that to which the name Finch, now so extended in its signification, originally belonged. *Fink*, the German form of the name, and *pink* and *twink*, still used in England as popular names, have some resemblance in sound to the common call-note of the chaffinch. The whole length of the bird is about six inches. The tail is very slightly forked. The beak is almost equal in breadth and height. The male, in summer, has the top of the head and nape of the neck bluish-gray; the back, chestnut; the wings almost black, with two conspicuous white bars; the tail nearly black. The lower surface is reddish. The colours of the female are much duller than those of the male. The chaffinch is a very widely distributed species, being found in almost all parts of Europe, in some parts of Asia, in the north of Africa, and as far west as the Azores. In the colder northern countries it is migratory; in more southern regions it is stationary. Linnaeus gave it the specific name *caelebs*, from observing that the flocks seen during winter in Sweden consisted chiefly of males, the females having, as he supposed, sought a milder climate. A partial separation of the sexes is observed also in the great winter-flocks in Britain, but it is only partial; and Yarrell thinks that the young males of the previous season, which resemble the females in plumage, are associated with them, and have been mistaken for them. The flocks seen in Britain in

winter are believed to be augmented by migration from Scandinavia. The eggs are usually four or five in number, of pale purplish buff colour, sparingly streaked and spotted with reddish brown. The chaffinch feeds in great part on insects, and does much service in summer by destroying aphides and caterpillars; but eats also seeds, and is sometimes persecuted, because in spring it pulls up and eats young turnips and radishes when in the seed-leaf. It is particularly fond of the seeds of beeches and conifers. Great numbers of chaffinches are killed for the table in Italy. In Germany this bird was formerly in the highest esteem as a song-bird. Its notes are very clear and loud, but some individuals greatly excel the ordinary multitude of their species.—The common Scotch name of the chaffinch is *Shilfa*.

Chagny, an important railway junction and commercial centre in the French department of Saône-et-Loire, on the Canal du Centre, 32 miles S. of Dijon. As the key of the roads to the Loire district, it has been strongly fortified. Pop. 4291.

Chagres, a town of the United States of Colombia, on the N. coast of the Isthmus of Panama, situated at the mouth of the Chagres River. It is a poor place, with a harbour for vessels drawing from 10 to 12 feet of water. The river of the same name rises about 10 miles NE. of Panama, makes an immense bend round to the NE., and enters the Caribbean Sea. Though towards its mouth it varies in depth from 16 to 30 feet, it is yet, by reason at once of its rapidity and its falls, but little available for navigation. The route of the Panama Canal (q.v.) is by the valley of the Chagres for part of its course; and the canal crosses the river repeatedly.

Chaillu, PAUL DU. See DU CHAILLU.

Chain, in Surveying (called Gunter's Chain, from its inventor, Edmund Gunter, q.v.), is a measure of 22 yards long, composed of 100 iron links, each of which is thus 7·92 inches long. As an acre contains 4840 square yards, 10 square chains (22 × 22 × 10 = 4840 square yards) or 100,000 square links make an acre.

Chain Cable. See CABLE.

Chain-mail, or CHAIN-ARMOUR, much used in Europe in the 12th and 13th centuries, and still

Piece of Chain-armour.

used in India and the interior of the Asiatic continent, consists of hammered iron links, connected together by riveted links so that each link embraces four others, and worked into the form of a garment. Such armour was much more flexible and convenient to the wearer than that which was formed of steel or brass plates, but was less fitted to bear the thrust of a lance. See ARMOUR.

Chain-plates, on shipboard (wood vessels), are iron plates bolted below the channels to serve as attachments for the dead-eyes, through which the standing rigging or shrouds and back-stays are rove and secured. In most of the modern iron-steel vessels *rigging-screws* take the place of the older *dead-eyes*, the chain-plates to which they are attached consisting simply of flat palms, having an eye projection, riveted to the inside of the *sheer* or top stroke of shell plating.

Chains. Chain-making being a distinct trade of itself, thoroughly reliable chains can only be

made by men trained to the work, although some of the very small sizes of common chains are made by women, boys, and girls. Chains are of two generally distinct kinds—short-link or unstudded (frequently called *close-link*) chain, and stud-link or stayed chain. The former usually embraces the smaller sizes of chain up to 1½ inches, and the latter comprises ships' cables and other heavy chains. Short-link chain is made in the following manner: The end of the bar from which the link is to be made is heated, then cut to gauge, and while still hot is bent into U-form; the free ends are then heated to a white heat and flattened or scarphed by a hammer, and in this state they are brought together and welded so as to form the other end of the link. The flattening or scarphing of the two ends and the closing of them being all done in one heat, the scarphed ends are again heated to welding-point, and the link is placed in a suitable recess under a hollow-faced tool, worked mechanically, which strikes the roughened weld and ultimately finishes it off as smooth as the other end of the link. The result is the finished link, and when the first has been completed, another piece of iron is bent in the same way and threaded or rove through it, and another link formed and finished in the same manner as the first. In this way each successive link is added until the required length of chain is made.

The foregoing illustrates the way in which chains generally are made, but as a rule, links of chains of 1-inch diameter and over are welded at the *side* instead of at the *end*, and a *stud* or stay-pin is welded across from side to side of the link. The larger sizes of chains and chain-cables are made by men, and the expert workman when employed making first-class chains of all descriptions gets an extra price for his skill and labour. Common (not to say inferior) chains, however, are too often welcomed by bargain-loving users if they can at all be made to pass the statutory tests. Chains which stand certain of the standard tests may be found totally unequal to meet certain others, and superior and inferior parts are often purposely mingled in one chain by dishonest makers to cheapen production and defeat the system of testing. The iron used for very superior chains is selected not only for its tensile strength and welding properties, but for its *ductility*, as high tensile strength is not infrequently possessed by a hard brittle iron, liable to snap upon the application of a sudden jerk, and therefore totally unsuited for chains. The system of testing cables followed by Lloyds' Register Society well exemplifies what should be adopted in the case of all chains. Every 15-fathom length is subject to a fair standard strain, sufficient to detect bad workmanship, by pulling asunder or opening any defective welds, yet not so severe as to injure the nature of the material by crystallising it—a result invariably produced by overstraining. This standard test, however, not being the extreme limit of strain which the chain ought to bear in actual use at sea, a few links are required to be cut out at random from any part of each 15-fathom length, and submitted to a so-called breaking strain of 50 per cent. in excess of the standard test. If these trial pieces are found to withstand this extra strain satisfactorily, they are then assumed to represent a fair average of the strength of that particular length to which they belong. This operation being gone through with satisfactory results in each length of cable, the whole is then passed, and certified accordingly. Any unsatisfactory lengths are condemned, marked, and sent back to the manufacturer.

In his treatise on *Chain Cables and Chains*, Mr T. W. Trail, surveyor-in-chief to the Board of

Trade, says: 'Since the Act of 1871, which came into operation in the early part of 1873, until the latter part of 1883, a period of about eleven years, nearly 165,000 tons of chain have been certified to, in accordance with the act of parliament, as having duly withstood the statutory tests, representing about 3,199,000 fathoms of chain, and for which it is computed that from about two and a quarter million to about two and a half million pounds sterling have been paid.'

Chain-shot, an obsolete artillery projectile, consisting of two balls connected by a short chain, formerly used to destroy the rigging of ships, &c. As case-shot and shrapnel shell answer the same purpose, its use has been discontinued.

Chalaza. The first layer of albumen deposited upon the yolk of an egg as it descends the bird's oviduct, is peculiarly viscous, and thus becomes twisted into two strands which keep the yolk in the middle of the more fluid albumen. These cords are also called *chalaza*.

Chalcedon, a city of ancient Bithynia, at the entrance of the Buxine, opposite to Byzantium. It was founded 684 B.C. by a colony from Megara, and soon became a place of considerable trade and importance. Taken by the Persians, it finally merged into the Roman empire, under which it was made a free city. Chosroes, the Persian, captured it in 616 A.D., after which it declined, until it was finally demolished by the Turks, who used its ruins to build mosques and other edifices at Constantinople. Chalcedon was the birthplace of the philosopher Xenocrates.

The council of Chalcedon was the fourth œcumenical council, and was assembled (451 A.D.) by the emperor Marcian for the purpose of drawing up a form of doctrine in regard to the nature of Christ which should equally avoid the errors of the Nestorians (q.v.) and Monophysites (q.v.). Six hundred bishops, almost all of the Eastern Church, were present. The doctrine declared to be orthodox was, that in Christ there were two natures, which could not be intermixed (this clause was directed against the Monophysites), and which also were not in entire separation (this was directed against the Nestorians), but which were so conjoined, that their union destroyed neither the peculiarity of each nature, nor the oneness of Christ's person.

Chalcedony (often misspelled *Calcedony*), a beautiful mineral of the quartz family, consisting of quartz with some admixture of opal. It derives its name from Chalcedon in Bithynia, near which it is found in considerable abundance, and has been known by the same name from ancient times. It never occurs in crystals, but usually in mammillary, botryoidal, or stalactitic forms, lining or entirely filling the cavities of rocks, and more particularly old igneous rocks, such as the basalt-rocks of Scotland, the Farøe Isles, Iceland, &c. It constitutes the whole or the principal part of many agates. It is generally translucent, sometimes semi-transparent, has a somewhat waxy lustre, and is in colour generally white or bluish white, sometimes reddish white, sometimes milk white, less frequently gray, blue, green, yellow, brown, or even black. Its fracture is even, or very slightly conchoidal. Chalcedony is much used in jewelry, for brooches, necklaces, and ornaments of all sorts, the largest pieces being sometimes made into little boxes, cups, &c. It was much used by the ancients, and many beautiful engraved specimens appear in antiquarian collections. Chalcedonies with disseminated spots of brown and red were once very highly prized, and were called *Stigmities* or *St Stephen's stones*. Petrified plants are sometimes found in chalcedony, in which they appear to have been incased whilst it was in course of formation. Specimens of chal-

cedony are sometimes found inclosing a little water in the interior, which gives them a very beautiful appearance; but the water easily escapes, and to prevent this, rings or other ornaments made of such stones are kept in distilled water when not worn. The ancients set a very high value on these *enhydrites* (Gr. *en*, 'in,' and *hydor*, 'water'). See JASPER.

Chalcedony (or, erroneously, *Calcedony*), a name given to agates formed of chalcholong, or a white opaque chalcedony, alternating with a grayish translucent chalcedony.

Chalchihuitl, the Indian name of a green-coloured stone, taken from a quarry near Santa Fé, and by some regarded as a species of turquoise, by others identified with Jade (q.v.). It was valued above gold by the ancient Mexicans, who fashioned it into beads and ornaments.

Chalcididae, a small family of short-tongued lizards, restricted to America. *Chalcides* (*C. flavescens*) occurs in tropical America. *Heterodactylus* is an allied Brazilian genus. The same title is applied to a family of insects. See CHALCIS.

Chalcis, the capital of the Greek island of Eubœa, on the Euripus, a strait separating the island from Boeotia, and here only 120 feet wide. Chalcis is a place of very great antiquity, and it soon became a great trade centre, sending out colonies to Macedonia, where the peninsula of Chalcidice commemorated its name, as well as to Campania (*Cuma*), South Italy, and Sicily. Successively Athenian, Macedonian, and Roman, it was a place of great military importance, nearly nine miles in circumference, and had many fine temples, theatres, and other public buildings. Aristotle died here. In the middle ages it was prosperous under the Venetians, who held it for nearly three centuries, until its conquest by the Turks in 1470. Pop. (1879) 6877.

Chalcis, a typical genus of a large family of Hymenopterous insects, not unlike small wasps. The family (Chalcididae or Pteromalini) has this great importance that the larvæ of its members are parasitic in the eggs, larvæ, or pupæ of other insects, and as some of the latter are very destructive to plants, their parasites are animals to be thankful for. Thus forms so different as the cabbage butterfly and the destructive Hessian fly have their attendant Pteromalini. Many of the so-called gall-wasps (Cynipidae) which cause many of the commonest galls—for instance on the oak, or the curious bunches on rose and briar bushes—are preyed upon by Chalcididae. Some of the hosts of these Chalcididae are themselves parasitic, and thus we have parasites within parasites, or double parasitism, there being in this case no honour among thieves. Altogether over 2000 species of Chalcididae are known.

Chaldaea. See BABYLONIA; for CHALDEE, see ARAMÆA.

Chalder, an old Scotch dry measure, containing 16 bolls. See BOLL and FIARS.

Chaldron (Lat. *caldarium*, 'a vessel for warm water'), an old dry measure used in selling coal, and containing 36 heaped bushels (= 25½ cwt.). Coal is now sold by weight.

Chalet is the French-Swiss name for the wooden hut of the Swiss herdsmen on the mountains; but is also extended to Swiss dwelling-houses generally, and to picturesque and ornate villas built in imitation of them.

Chaleurs, BAY OF, an inlet of the Gulf of St Lawrence, between Gaspé, a district of Quebec, and New Brunswick, having a depth of 80 miles from east to west, and a width varying from 12 to 20. It is deep and well sheltered, and much frequented for its mackerel fisheries.

CHALFONT ST GILES

Chalfont St Giles, a village of Buckinghamshire, 16 miles SE. of Aylesbury. Milton's cottage (1665) still stands here.

Chalgrove, a village 13 miles SE. of Oxford, the scene of a skirmish in the Civil War between Prince Rupert's cavalry and a parliamentary force under Hampden, in which that patriot received his death-wound, June 18, 1643.

Chalice (Lat. *calix*, 'a cup'). The name has long been applied only to the cups used for the administration of the wine in the holy communion. Anciently made of glass, precious stone, horn, and

other substances, chalices have for many centuries been formed of silver, or sometimes gold, occasionally enriched with jewels. Their fashion has followed the art of the times, the hemispherical bowl and plain circular foot of Romanesque or Norman days giving way to a conical bowl and hexagonal foot in the Perpendicular period, and these in turn to more modern shapes, seldom of

Chalice (1459) at Nettlecombe, County Somerset.

(From Cripps's *Old English Plate*.)

such beauty and excellence as those of Gothic design. Before the Reformation a crucifix or other sacred device always occupied one side of the foot. The chalice was usually accompanied by a paten, which might serve as a cover to the bowl, as well as for carrying the wafer or bread. In medieval times a chalice of tin or pewter, if not of silver, was placed in the coffin of ecclesiastics at burial. The chalice is the emblem of St John the Evangelist. Old chalices are much sought after by collectors. The glass 'Luck of Edenhall,' preserved in the family of Musgrave, near Penrith, is apparently an old chalice. The use of the *mixed* chalice, the mingling of water with the wine used in the Lord's Supper, and in the Roman rite, has been matter of controversy in the Church of England. The chalice veil or corporale was a covering for the chalice.

Chalk, a soft earthy variety of limestone or carbonate of lime, forming great strata, and claiming the attention of the geologist even more than of the mineralogist (see CRETACEOUS SYSTEM). It is generally of a yellowish-white colour, but sometimes snow-white. It is easily broken, and has an earthy fracture, is rough and very meagre to the touch, and adheres slightly to the tongue. It generally contains a little silica, alumina, or magnesia, sometimes all of these. Although often very soft and earthy, it is sometimes so compact that it can be used as a building-stone; and it is used for this purpose either in a rough state, or sawn into blocks of proper shape and size. It is burned into quicklime, and nearly all the houses in London are cemented with mortar so procured. The siliceous particles being separated by pounding and diffusing in water, it becomes whiting, of which the domestic uses are familiar to every one. Carpenters and others use it for making marks, which are easily effaced: the *blackboard* and piece of chalk are now common equally in the lecture-rooms of universities and in the humblest village-schools. Chalk, per-

fectly purified, is mixed with vegetable colours, such as turmeric, litmus, saffron, and sap-green, to form pastel colours or coloured chalks; but vegetable colours which contain an acid are changed by it (see CRAYON). The *Vienna white* of artists is simply purified chalk. In a perfectly purified state it is administered as a medicine to correct acidity in the stomach. Chalk is also extensively used as a manure. See LIME, MANURE.

BLACK CHALK is a mineral quite different from common chalk, and apparently receives its name from resembling it in meagreness to the touch, in soiling the fingers, and in being used for drawing, writing, &c. It is also called Drawing-slate. It is of a slaty structure, of a bluish or grayish-black colour, easily cut and broken, and makes a perfectly black mark on paper. It is used for drawing and as a black colour in painting. It becomes red by exposure to heat. It is essentially a kind of Clay (q.v.), and derives its colour from carbon, which it contains. It is found associated with schists, &c. in Spain, France, Italy, &c., also in the coal formation in Scotland.—**BRIANÇON CHALK** and **FRENCH CHALK** are popular names for Soapstone (q.v.).—**RED CHALK** is *ochry red clay-iron ore*, consisting of clay and much peroxide of iron. It is of a brownish-red colour, and a somewhat slaty structure, the cross fracture earthy. The coarser varieties are used chiefly by carpenters for making marks on wood; the finer, by painters. It occurs in thin beds in clay-slate and graywacke-slate in some parts of Germany.

Chalking the Door, a mode of warning tenants to remove from burghal tenements, long known and still in use in Scotland. It is thus described by Hunter in his work on Landlord and Tenant: 'A burgh-officer, in presence of witnesses, chalks the most patent door forty days before Whitsunday, having made out an execution of 'chalking,' in which his name must be inserted, and which must be subscribed by himself and two witnesses. This ceremony now proceeds simply on the verbal order of the proprietor. The execution of chalking is a warrant under which decree of removal will be pronounced by the burgh court, in virtue of which the tenant may be ejected on the expiration of a charge of six days. See EJECTMENT.

Challenger Expedition, a circumnavigating scientific exploration of the open sea sent out by the British government in 1872-76—earlier expeditions being those of the *Lightning* (1868) and *Porcupine* (1870). In 1872 the *Challenger*, a corvette of 2306 tons, was completely fitted out and furnished with every scientific appliance for examining the sea from surface to bottom—natural history work-room, chemical laboratory, aquarium, &c. The ship was given in charge to a naval surveying staff under Captain Nares; and to a scientific staff, with Professor (afterwards Sir) Wyville Thomson at their head, for the purpose of sounding the depths, mapping the basins, and determining the physical and biological conditions of the Atlantic, the Southern and the Pacific Oceans. With this new commission, the *Challenger* weighed anchor at Sheerness on the 7th December 1872, and on the evening of the 24th May 1876 she dropped anchor at Spithead, having in these three and a half years cruised over 68,900 nautical miles, and made investigations at 362 stations, at each of which were determined the depth of channel; the bottom, surface, and intermediate temperatures, currents, and fauna; and the atmospheric and meteorological conditions. The route was by Madeira, the Canaries, the West Indies, Nova Scotia, Bermudas, Azores, Cape Veri, Fernando Noronha, Bahia, Tristan d'Acunha, Cape of

Good Hope, Kerguelen, Melbourne, the Chinese Sea, Hong Kong, Japan, Valparaiso, Magellan's Strait, Monte Video, Vigo, and Portsmouth. Between the Admiralty Isles and Japan the *Challenger* made her deepest sounding, on the 23d March 1875, 4575 fathoms (equal to a reversed Himalaya), the deepest sounding on record except two. See the copious *Reports on the Scientific Results of the Voyage of H.M.S. Challenger*, edited by Sir Wyville Thomson and Dr John Murray, which mark an era in deep-sea exploration. They fall into a *Narrative* (2 vols. 1882-85), *Zoology* (30 vols. 1880-89), *Physics and Chemistry* (3 vols. 1884-89), *Botany* (2 vols. 1885-86). To these invaluable reports many articles in the present work are indebted for materials and illustrations. See also the works of Sir C. Wyville Thomson, H. M. Moseley, Spry, Lord George Campbell, Wild; and the articles in this work on ATLANTIC OCEAN, PACIFIC OCEAN, SOUNDING, and especially SEA.

Challis, JAMES, astronomer, born at Braintree in Essex, 12th December 1803, graduated senior wrangler and first Smith's prizeman at Cambridge in 1825, was ordained in 1830, and in 1836 became professor of Astronomy at Cambridge, where he died 3d December 1882. He was also till 1861 director of the Cambridge Observatory, and published a number of works, including 12 vols. of astronomical observations (1832-64). In August 1846, whilst carefully preparing to test Adams' results, he twice unconsciously noted the position of the planet Neptune before its discovery at Berlin on 23d September. See ADAMS (J. C.).

Challoner, RICHARD, a learned Roman Catholic prelate, born at Lewes in Sussex, September 29, 1691. Becoming a Roman Catholic, he was sent in 1704 to the English College at Douay, where he became a professor, and remained until 1730. In that year he was sent to labour in London, and here he served as a missionary priest until 1741, when he was raised to the episcopal dignity as Bishop of Debra and coadjutor of Bishop Petre, whom he succeeded as Vicar Apostolic of the London district in 1758. During the 'No Popery' riots of 1780 he was secreted near Highgate, and he died in London, January 12, 1781. Of Challoner's numerous controversial treatises, the best known is his *Catholic Christian Instructed*, an answer to Conyers Middleton's *Letters from Rome*. His *Garden of the Soul* is still the most popular prayer-book with English Catholics, and his revision of the Douay version of the Bible (5 vols. 1750) is substantially the Bible used by them. Of his historical works the most valuable are his memoirs of missionary priests and other Catholics of both sexes who suffered death or imprisonment in England on account of their religion, from the year 1577 till the end of the reign of Charles II. (2 vols. 1741), and his *Britannia Sancta* (2 vols. 1745), a collection of the lives of British and Irish saints.

Chalmers, ALEXANDER, an industrious biographer and miscellaneous writer, was born at Aberdeen in 1759. After a course of study at his native university, he abandoned a projected medical career, and repaired to London, where he soon became an active writer for the press and the busiest of booksellers' hacks. He died in London, 10th December 1834. His editions of Burns, Beattie, Fielding, Gibbon, Bolingbroke, Shakespeare, Johnson, and Boswell's Johnson are now of no importance; but that of *The British Essayists*, in 45 vols., is still esteemed as accurate and handy. His prefaces to 'Walker's Classics (45 vols.), and his enlarged edition of Johnson's *Collection of the Poets* (21 vols.), contain much honest work. But his reputation depends mainly on the *General Biographical Dictionary* (32 vols. 1812-14).

Chalmers, GEORGE, Scottish antiquary, was born in 1742 at Fochabers in Elginshire, and was educated there and at King's College, Aberdeen. Having afterwards studied law at Edinburgh, in 1763 he went to North America, where he practised as a lawyer at Baltimore till the breaking out of the war of independence. Then returning to Britain, he settled in London (1775), and was appointed clerk to the Board of Trade in 1786. The duties of this office he continued to discharge with diligence and ability till his death on 31st May 1825. Of his thirty-three works the chief is *Caledonia; an Account, Historical and Typographical, of North Britain* (vols. i.-iii. 1807-24). In 1888-89 it was reprinted at Paisley in 7 vols., comprising the matter prepared for the unpublished 4th vol., and furnished with a much-needed index. Among his other publications are *A Collection of Treaties between Great Britain and other Powers* (2 vols. 1790); *Lives of Defoe, Paine, Ruddiman, and Mary, Queen of Scots*; and editions of Allan Ramsay and Lyndsay.

Chalmers, GEORGE PAUL, R.S.A., was born at Montrose in 1833 (not 1836). He served as errand-boy to a surgeon, and apprentice to a ship-chandler; but he was resolved to become an artist, and in 1853 he came to Edinburgh, and studied under Scott Lander. His 'Favourite Air,' attracted attention in 1854, and in 1867 he was elected an A.R.S.A., in 1871 an R.S.A. His untimely death at Edinburgh (23th February 1878) was due to injuries received some days before either from violence or by misadventure. His works are distinguished by admirable breadth, effective concentration of lighting, freedom of handling, and rich and powerful colouring. He executed some important portraits. His landscapes, mainly of his later years, include 'End of the Harvest' (1873) and 'Running Water' (1875). He is represented in the National Gallery of Scotland by 'The Legend,' a large unfinished subject-picture, which, like 'Prayer' (1871), has been etched by Rajon. See his Memoir (1879).

Chalmers, THOMAS, D.D., LL.D., was born at Anstruther, in Fife, 17th March 1780, educated at the university of St Andrews (from 1791), and at the age of nineteen licensed to preach the gospel. In 1803 he was ordained minister of the parish of Kilmany, in Fifeshire, about 9 miles from St Andrews. At this period his attention was almost entirely absorbed by mathematics and natural philosophy. He carried on mathematical and chemistry classes in St Andrews during the winter of 1803-1804, and by his enthusiasm and lucidity of exposition obtained for himself a high reputation as a teacher. In 1808 he published an *Inquiry into the Extent and Stability of National Resources*. Shortly after this, domestic calamities and severe illness rendered him keenly susceptible of religious impressions. Having to prepare an article on Christianity for Brewster's *Edinburgh Encyclopedia*, he commenced a thorough study of the evidences, and rose from his investigations convinced that Christianity was the truth, and the Bible the veritable 'word of God.' Then the great genius of the man broke forth like sunshine. He grew earnest, devout, and faithful to his pastoral duties. In July 1815 he was translated to the Tron Church and parish, Glasgow, where his magnificent oratory took the city by storm. His *Astronomical Discourses* (1817) and *Commercial Discourses* (1820) had a widely extended popularity. In 1817 he visited London, where his preaching excited as great a sensation as at home. But Chalmers' energies could not be exhausted by mere oratory. Discovering that his parish was in a state of great ignorance and immorality, he began to devise a scheme for overtaking and checking

the alarming evil. It seemed to him that the only means by which this could be accomplished was by 'revivifying, remodelling, and extending the old parochial economy of Scotland,' which had proved so fruitful of good in the rural parishes. In order to wrestle more closely with the ignorance and vice of Glasgow, Chalmers in 1819 became minister of St John's parish, of whose 2000 families, mostly workpeople, more than 800 had no connection with any Christian church. Chalmers broke up his parish into 25 districts, each of which he placed under separate management, and established two day schools, and between 40 and 50 local Sabbath schools, for the instruction of the children of the 'poorer and neglected classes,' more than 1000 of whom attended. In many other ways he sought to elevate and purify the lives of his parishioners. While in Glasgow, Chalmers had matured his opinions relative to the best method of providing for the poor. He disliked the English system of a 'compulsory assessment,' and preferred the old Scotch method of voluntary contributions at the church-door, administered by elders. The management of the poor in the parish of St John's was intrusted to his care by the authorities as an experiment, and in four years he reduced the pauper expenditure from £1400 to £280 per annum. Edward Irving was for two years his assistant. But such herculean toils began to undermine his constitution, and in 1823 he accepted the offer of the Moral Philosophy chair in St Andrews, where he wrote his treatise on the *Use and Abuse of Literary and Ecclesiastical Endowments* (1827). In the following year he was transferred to the chair of Theology in Edinburgh, and in 1832 he published a work on political economy. In 1833 appeared his Bridge-water treatise, *On the Adaptation of External Nature to the Moral and Intellectual Constitution of Man*. It was received with great favour, and obtained for the author many literary honours; in 1834 he was elected by the Royal Society of Edinburgh first a fellow and then a vice-president, and by the French Institute a corresponding member, while in 1835 the university of Oxford conferred on him the degree of D.C.L. In 1834 he was appointed convener of the Church-extension Committee; and after seven years of enthusiastic labour, he announced that upwards of £300,000 had been collected from the nation, and 220 new churches built. Meanwhile, however, troubles were springing up in the bosom of the church itself. The Evangelical party had become predominant in the General Assembly; the struggles in regard to patronage between them and the 'Moderate' or 'Erastian' party became keener and more frequent, until the decision of the civil courts in the famous Auchterarder and Strathbogie cases brought matters to a crisis; and on the 18th of May 1843 Chalmers, followed by 470 clergymen, left the church of his fathers, rather than sacrifice those principles which he believed essential to the purity, honour, and independence of the church (see FREE CHURCH). The rapid formation and organisation of the Free Church were greatly owing to his indefatigable exertions. Chalmers was elected principal of the Free Church College, and spent the close of his life in the zealous performance of his duties there, and in completing his *Institutes of Theology*. He died suddenly at Morningside, Edinburgh, May 30, 1847.

The works of Chalmers extend to 34 vols. (9 of which include his posthumous works). They contain valuable and, in some cases, original contributions to the sciences of natural theology, Christian apologetics, and social economy; while on minor topics, such as the church-establishment question, they exhibit both novelty and ingenuity

of argument. As a religious orator Chalmers was unique and unrivalled. There have been few men in whom such gifts of intellect, feeling, and imagination were so harmoniously combined with the shrewdest common-sense and the highest administrative ability. Never did Scotland produce a greater or more lovable soul, one more gentle, guileless, and genial-hearted, or yet more fervid from the strength of a resolute will, before whose impetus difficulties were dashed aside as by a torrent. There have been loftier and more purely original minds in Scotland than Chalmers's, but there has never been a truer one, nor a heart whose Christian faith and piety were more intense, sincere, and humane. See his *Memoirs*, by his son-in-law, Dr W. Hanna (4 vols. 1849-52), and a *Selection from the Correspondence of the late Thomas Chalmers* (1853); also *A Biographical Notice* by Dean Ramsay (1850), and an Essay by Dr John Brown in his *Hours Subsecivæ*.

Châlons-sur-Marne, the capital of the French department of Marne, on the right bank of the river Marne, 107 miles E. of Paris by rail. An old place, with timber houses and many spired churches, it has an interesting cathedral, dating chiefly from the 13th century, a handsome hôtel-de-ville (1772), and a fine public park, though the Germans cut down its immemorial elms for fuel. It still does a considerable trade in Champagne wine; but its manufacture of the worsted cloth known as 'shalloon' (Chancer's *châlons*) is a thing of the past, and the population has dwindled from 60,000 in the 13th century to 23,636 in 1886. Near Châlons, which takes its name from the *Catalauni* of Latin writers, the Romans and Goths in 451 A.D. defeated Attila (q.v.) and his host of Huns. In 1856 Napoleon III. formed the celebrated camp of Châlons, 16½ miles to the north-east of the town. Hence, during the Franco-Prussian war, on the night of August 21, 1870, MacMahon withdrew his troops, and next day the town was occupied by the Germans.

Châlon-sur-Saône (ancient *Cabillonum*), a town in the French department of Saône-et-Loire, 84½ miles by rail N. of Lyons. Lying on the right bank of the Saône, at the point where that river is joined by the Canal du Centre, uniting it with the Loire, Châlon has an extensive traffic with the central districts of France, as well as with the Mediterranean and Atlantic. Fine quays and houses line the river; and the chief building is the church of St Vincent, 14th to 15th century. The industries are copper and iron founding, machinery and shipbuilding, and the manufacture of glass, paper, and chemicals. Pop. (1872) 20,055; (1886) 22,208.

Chalybæus, HEINRICH MORITZ, philosopher, born at Pfaffroda in Saxony, 3d July 1796, spent some years in teaching, and was appointed in 1839 professor of Philosophy in the university of Kiel. He was dismissed, however, in 1852, owing to his Germanic sympathies, and died at Dresden, 22d September 1862. His chief work is his *System der speculativen Ethik* (1850); and his review of the historical development of speculative philosophy has been translated into English by Tulk (1854) and Edersheim (1860).

Chalybæate Waters are those which contain a considerable portion of iron in solution. See MINERAL WATERS.

Chalybite, an iron ore. See IRON.

Cham, the pseudonym assumed by the caricaturist, Amédée de Noé (*Cham* being the French for *Ham*, the son of Noah), son of the Comte de Noé by an English mother, and born at Paris in 1819. He studied art under Delaroche,

and soon acquired a great reputation as a skilful and witty delineator of the humorous side of Parisian life. In 1843 began his famous connection with the *Charivari*, in which paper and in the *Journal des Pèlerins* he continued to delight his fellow-citizens until close upon his death on 6th September 1879. He was profoundly sceptical, but not unkindly, and obtained, as Edmond About pointed out, the success of an *homme d'esprit*. His masterpieces were chiefly social rather than political, and among his skits may be mentioned *Proudhomana*, *Baigneurs et Baveurs d'Eau*, *Souvenirs de Garrison*, and *L'Exposition de Londres*. Several good collections of his comic illustrations have been made—for instance, *Douze Années Comiques* (1880), with an introduction by L. Halévy, and *Les Folies Parisiennes* (1883), with an introduction by Gérôme. In Sala's *Paris herself again* (1882) are a good many specimens of Cham's art.

Chama, a genus of bivalve molluscs, the only surviving type of a family which was once extremely numerous and abundant, especially in the Jurassic and Chalk times. The genus is represented by about half a hundred living forms, restricted to warmer waters, and especially common about coral reefs. The general appearance is somewhat clam-like, the valves are unequal, of considerable thickness, and covered with leaf or scale-like outgrowths. They are very passive animals, usually fixed, with the mantle margins fused together, with very small foot and respiratory apertures, with well-developed hinge and an external ligament, and often of a bright colour. Some forty fossil species are known from Cretaceous and Tertiary strata, and the genus is of interest as the sole survivor of a once much larger family.

Chamade. See PARSLEY.

Chamæleon (Gr. *chamaileōn*, 'ground lion'), a large genus of lizards, forming a very distinct family. Among the most distinctive features may be noted the soft tuberculated skin, with its power of changing colour; the coiled tail, adapted for curling round the branches of trees; the division of the toes of fore and hind feet into two bundles; the absence of an external ear-drum or tympanic membrane; the long worm-like insect-catching tongue, capable of extremely rapid protrusion. Even more remarkably distinctive, however, are certain peculiarities in the skeleton, and especially in the skull, which separate the chamæleons from all other lizards.

Description.—The body is flattened, and bears a toothed crest of skin along the back. The head is

Chamæleon.

triangular, surmounted by a ridge. The animal stands unusually high upon its legs. The fore-feet are divided into three united internal digits and two external; the reverse (and the digits, corresponding to our great and second toes, form one bundle, and the other three—external—another

united group) occurs in the hind-feet. The digits are tipped by long sharp claws. The long compressed tail is curled ventrally. The mouth-aperture is small, but the tongue extremely long. It is the most active part of the animal, is cup-shaped at the end, covered with a viscid secretion, and very efficient in insect-catching. The large lateral eyes, with circular lids leaving only a small aperture, are very active, and can be rapidly turned in all directions, a possibility which to some extent compensates for the stiffness of the head. The skin is soft, loose, and shagreen-like, the scales being very small. The glandular pores common on the thighs and near the anus of lizards are absent.

Among the internal peculiarities may be noted the largeness of the lungs, which admit of being greatly distended, so as to puff out the body into marked plumpness. They appear to be connected with surrounding air-spaces. The habit the chamæleon has of thus blowing itself out, taken along with its power of fasting, gave origin to the ancient supposition that it fed on air. The skeletal peculiarities are numerous. The chamæleons differ from all lizards except the *Amphisbænas* (q.v.), in having no 'columnella' or epipterygoid skull-bone, and no interorbital septum, and from all other forms in the fact that the pterygoid and quadrate bones are not united. The latter is firmly fused to the skull, and the parietals are also peculiar in their firm attachments. The teeth are confined to a ridge along the summit of the jaws. The vertebrae are hollow in front; the breastbone is small, and only a few anterior ribs reach it; as in the geckos, many of the posterior ribs are united ventrally by hoops across the abdomen; there are no clavicles; the scapula and coracoid of the shoulder-girdle and the ilia of the hip-girdle are peculiarly long and narrow.

Life and Habit.—Except as regards tongue and eyes, the chamæleons are very sluggish. They are strictly arboreal lizards, moving very slowly, in perfect silence, and waiting rather than hunting for their insect prey. At a distance of several inches, about half as long as the body in some cases, they can most unerringly catch the unconscious insect. Probably the most familiar fact about chamæleons is their power of changing colour. Under the thin outer skin there are two layers of pigment-containing cells, the outer bright yellow, the inner brown to black. Under nerve control the disposition and expansion of the pigment-containing cells vary, and this produces change of colour. The change depends much more on internal emotions, expressing themselves in nervous stimulus and inhibition, than on external physical influences. The change appears to be rather emotional than protective. Most chamæleons are oviparous, and lay 30 to 40 thin-shelled eggs, which are deposited in an excavated hollow and covered over with earth and leaves. Moseley has described a South African species which brings forth its young alive.

Species and Distribution.—The genus *Chamaeleo* is a large one, and some naturalists split it up. Chamæleons are especially at home in the Ethiopian region, but may occur beyond its limits. The commonest of the numerous species is *C. vulgaris*, which is abundant in Africa, and is also found in South Europe (Andalusia). The predominant colour varies in different species. Many males are adorned with horns on the head. One form, distinguished as a distinct genus (*Rhampholeon*), has a tail too short for clasping purposes, but this loss is made up for by accessory structures on the feet. The chamæleon was well described by Aristotle, but in later days became the subject of numerous ridiculous fables. It was also in repute

for supposed medicinal virtues. See LIZARD; Huxley's *Anatomy of the Vertebrates*; St George Mivart in *Nature*, vol. xxiv.; Krukenberg's *Vergleichend-Physiol. Studien*, i. 3 (1880), for colour change.

Chamærops, a genus of palms, remarkable for its wide range into northern climates throughout the world, and of which one species, *C. humilis*, is the only palm truly indigenous to Europe. This species, the common Fan-palm, is widely distributed through Southern Europe, extending as far north as Nice. This palm is so tolerant of a cold climate, that a specimen has lived in the open air in the Botanic Garden of Edinburgh for more than fifty years, with the protection of matting in very severe winters. It forms dense furze-like thickets from the suckers which arise from its creeping roots, but when these are not allowed to grow, its stem may reach a height of 20 feet or more. In Algeria it is troublesome to agriculturists, but its growth is increasingly becoming of profit on account of the excellent fibre yielded by its stem. This the Arabs mix with camel's hair and make into hut-covers, &c.; cordage and sailcloth, paper and pasteboard, are also prepared from it, and it also finds many uses under the title of vegetable or African horse-hair. The leaves are also used in paper-making, and furnish a convenient thatching material. This species is sometimes called *palmetto* in Europe. The true *Palmetto* (q.v.) is *C. (Sabal) palmetto* of Florida and Carolina (see also BRAZILIAN GRASS). In China and Japan *C. excelsa* and *C. Fortunei* are specially prominent; both can be grown in the open air in the south of England.

Chamalari, a peak (23,944 feet) of the Himalayas, between Tibet and Blutan, 140 miles E. of Mount Everest.

Chamba, one of the Punjab Hill States, immediately SE. of Cashmere, with an estimated area of 3180 sq. m. Pop. (1881) 115,773, nearly all Hindus. It is shut in on nearly all sides by lofty hills, and traversed by two ranges of snowy peaks and glaciers, with fertile valleys to the south and west. The banks of the Ravi and Chenab, two of the five great Punjab rivers, are clothed with mighty forests, leased to the British government, which takes £10,000 to £20,000 worth of timber from them every year. Agriculture and grazing are the leading industries; iron, copper, and slate are plentiful; and the mountains teem with game. The principality came into the hands of the British in 1846, who in 1847 assigned it to the present line of rajahs; an annual tribute is paid, reduced, since the establishment of a British sanatorium and two cantonments among the hills, to £500.

Chambal, a principal tributary of the Jumna River, rises in the Vindhya Range, 2019 feet above sea-level, flows in a north-easterly direction, and after a course of 650 miles falls into the Jumna 40 miles below the town of Etawah. In heavy rains its volume is greater than that of the Jumna.

Chamber, of a firearm, is the name given to that part of the bore which contains the powder, when its diameter is not the same as the Calibre (q.v.) of the gun. Formerly, chambers were always smaller in diameter than the bore, to prevent any air-space behind the projectile, but now that much heavier charges are fired, they are made larger. They tend to weaken the gun, but enable a shorter cartridge to be used, and so prevent the dangerous wave action which would be set up in a long one. See CANNON, RIFLED ARMS.

Chamberlain, an officer appointed by a king or nobleman, or by a corporation, to perform domestic and ceremonial duties. The LORD CHAMBERLAIN has been one of the principal officers

of state from at least the 13th century, and in 1406 parliament declared that he should always be a member of the council *ex officio*. Though he has long ceased to have any share in the responsibilities of government, the Chamberlain is still an officer of very high standing in the royal household. He has control over all the officers and servants 'above stairs,' except those of the bedchamber, over the establishment attached to the Chapel Royal, the physicians, surgeons, and apothecaries of the household. The chamberlain has further the oversight of the royal musicians, comedians, trumpeters, messengers, &c. When the office of Keeper of the Great Wardrobe was abolished in 1782, the duties of providing the state robes of the royal family, the household, and officers of state, devolved on the Lord Chamberlain. All theatres in towns in which a royal palace is situated require to be licensed by the Lord Chamberlain, and no new play can be performed anywhere without his license. His duties as licenser of theatres and plays are defined by acts passed in 1751 and 1843 (see PLAYS, LICENSING OF). All persons desiring to be presented at levees or drawing-rooms require to send their cards to the Lord Chamberlain, and it is his duty to see that the persons thus applying are entitled by station and character to be presented to the sovereign. The Chamberlain also issues invitations to royal balls, parties, and receptions. In accordance with ancient custom the Lord Chamberlain is still a member of the Privy-council. His salary is £2000 a year, but his tenure of office depends on that of the political party to which he belongs.

The *Vice-chamberlain* is the deputy and assistant of the Lord Chamberlain, and in his absence exercises the full authority which belongs to his principal. His office existed in the time of Richard II. He is also dependent on the administration, and is usually a member of the Privy-council. His salary is £924 per annum.

Chamberlain, THE LORD GREAT, is a hereditary officer of great antiquity, and formerly of great importance. He has the government of the palace at Westminster, and upon solemn occasions the keys of Westminster Hall and of the Court of Requests are delivered to him. At these times the Gentleman Usher of the Black Rod, the Yeoman Usher, and the door-keepers are under his orders. At coronations, state trials, banquets, and the like, the fitting-up of the Hall devolves on him. When the King goes to parliament, the Lord Great Chamberlain delivers the sword of state to any member of the administration whom he chooses, to be borne before His Majesty, he himself walking on his right hand. During the sitting of parliament he has charge of the House of Lords, and issues tickets of admission on the opening or prorogation of parliament. Some fees and perquisites belong to him. This office was conferred by Henry I. in 1101 on Alberic de Vere. Mary, daughter of John de Vere, sixteenth Earl of Oxford, married Peregrine Bertie, the 'brave Lord Willoughby' (1555-1601); and on the death of their last male descendant in 1779, the honour, after much litigation, was adjudged to belong conjointly to his sisters and co-heiresses—e.g. the Lady Willoughby de Eresby and the Marchioness of Cholmondeley, by whose descendants or their deputies its duties have since been discharged alternately.

Chamberlain, THE RIGHT HON. JOSEPH, M.P., is the eldest son of the late Mr Joseph Chamberlain, and was born in London in July 1836. He was educated at University College School, and entered his father's screw factory at Birmingham (the name of the firm being Nettlefold), from which,

however, he retired in 1874. Mr Chamberlain had by this time acquired considerable celebrity as a Radical politician. In 1868 he was appointed a member of the Birmingham Town-council; was Mayor of Birmingham from 1873 to 1876, and chairman of the Birmingham School-board from 1874 to 1876. After unsuccessfully contesting Sheffield against Mr Roebuck in 1874, he was returned for Birmingham without opposition in June 1876. He soon made his mark in parliament, and on the return of the Liberals to power in 1880 he was appointed President of the Board of Trade, with a seat in the cabinet. To Mr Chamberlain's exertions was due the passing of the Bankruptcy Bill, but his efforts to amend the Merchant Shipping Acts were unsuccessful. Meanwhile his influence was increasing rapidly outside the House; he came to be regarded as the leader of the extreme Radical party, and enunciated schemes for the regeneration of the masses which were based on the doctrines of the 'restitution' of land and the 'ransom' of property. During the last hours of Mr Gladstone's government he was understood to be opposed to the renewal of the Irish Crimes Act; and during the general election of 1886 he was most severe in his strictures on the moderate Liberals, and produced an 'unauthorised' programme (in opposition to that of Mr Gladstone), which included the readjustment of taxation, free schools, and the creation of allotments by compulsory purchase. He was returned free of expense by the western division of Birmingham. On February 1, 1886, he became President of the Local Government Board, but resigned on March 26 because of his strong objections to Mr Gladstone's Home Rule measures for Ireland; and after the 'Round Table' conference had failed to reunite the Liberal party he assumed an attitude of uncompromising hostility to his old leader's new policy. His visit to Ulster in the autumn of 1887 did much to strengthen the Unionist cause there. Shortly afterwards he went to America, having been appointed by Lord Salisbury one of the British High Commissioners to settle the fishery disputes between the United States and Canada. He succeeded in concluding a provisional arrangement pending the ratification or rejection of the treaty by the American Senate. He has contributed several political articles to the *Fortnightly Review*, and a selection of his speeches has been published, with an introduction by Mr H. W. Lucy.

Chamber Music is music specially fitted for performance in a room, as distinguished from concert or church music or opera. The name applies more particularly to instrumental music for a single instrument or a small combination, up to the septett or octett.

Chamber of Commerce, a body of merchants, traders, bankers, and others, associated for the purpose of promoting the interests of its own members, of the town or district to which the society belongs, and of the community generally, in so far as these have reference to trade and merchandise. Of the means for the accomplishment of these objects the following may be mentioned as the most prominent: (1) Representing and urging on the legislature the views of their members in mercantile affairs; (2) aiding in the preparation of legislative measures having reference to trade, such, for example, as the Bankrupt and Limited Liability Acts; (3) collecting statistics bearing upon the staple trade of the district; (4) acting in some places as a sort of court of arbitration in mercantile questions; (5) attaining by combination advantages in trade which might be beyond the reach of individual enterprise.

The oldest chamber of commerce is that of

Marseilles, which dates from the end of the 14th or commencement of the 15th century. It shared in the municipal jurisdiction and in the administration of justice in mercantile questions. It was several times suppressed and re-established, and it was not till 1650 that it received its ultimate organisation. The chamber of Dunkirk was established in 1700. The same year a council-general of commerce was instituted at Paris, which, in addition to six councillors of state, consisted of twelve merchants or traders, delegated by the principal commercial towns of the country, an arrangement which led within the next few years to the formation of chambers of commerce everywhere in France. We thus find that the chamber at Lyons was instituted in 1702, those of Rouen and Toulouse in 1703, of Montpellier in 1704, of Bordeaux in 1705, &c. These chambers were all suppressed by a decree of the National Assembly in 1791, but they were re-established by a consular edict in 1802. Their organisation was modified in 1832, in 1851, and in 1852. The members of these bodies are now elected by the chief merchants of each town chosen for that purpose by the prefect. The number of this elective body cannot be less than 9 nor more than 21. They hold office for six years, one-third of their number being renewed every two years. The functions now assigned to these chambers in France are—to give to the government advice and information on industrial and commercial subjects; to suggest the means of increasing the industry and commerce of their respective districts, or of improving commercial legislation and taxation; to suggest the execution of works requisite for the public service, or which may tend to the increase of trade or commerce, such as the construction of harbours, the deepening of rivers, the formation of railways, and the like. On these and similar subjects the advice of the chambers, when not volunteered, is demanded by the government. In most of the other countries of continental Europe there are similar institutions.

The oldest chamber of commerce in Great Britain is believed to be that of Glasgow, which was instituted 1st January 1783, and obtained a royal charter, registered at Edinburgh on the 31st of the same month. That of Edinburgh was instituted in 1785, and incorporated by royal charter in 1786. The Edinburgh Chamber of Commerce was the first public body which petitioned for the abolition of the Corn Laws, and the adoption of free-trade principles; and it stood almost alone in the United Kingdom in advocating the Suez Canal project. It also originated the movement which resulted in placing the telegraph service in connection with the Post-office. Between five and six hundred of the bankers, merchants, and ship-owners of Edinburgh and Leith constitute the chamber. The London Chamber of Commerce (1882) may now be regarded as the most important in the United Kingdom. The main branches of commercial enterprise are dealt with by separate departments of the chamber, while by public lectures and the frequent publication of detailed reports it maintains communication with chambers of commerce throughout the country, and serves when necessary to unite and concentrate their action in the promotion of reforms in our mercantile system and in the development of the commercial resources of the empire. The Manchester chamber, so famous for its exertions in the cause of free trade, was not established till 1820, and for many years it continued to be the only institution of the kind in England. Its members number over 900. In Hull there has been a chamber of commerce since 1837, but those of Liverpool, Leeds, and Bradford, notwithstanding the great trading and manufacturing

interests of these towns, were not established till 1850; in which year also a similar institution was established in South Australia. The Liverpool Chamber of Commerce numbers 550. The annual income of the Manchester chamber is upwards of £1400, contributed entirely by the subscriptions, ranging from £1, 1s. for individual members, to £10, 10s. for large firms. There are now similar chambers in all the great mercantile towns of Great Britain and Ireland, and in 1860 there was established an 'Association of Chambers of Commerce of the United Kingdom,' which meets in annual conference for the promotion of commerce. The Chamber of Commerce of New York, organised in 1768, was incorporated by a royal charter in 1770, afterwards superseded by charter granted by the state government. Its aims are similar to those in Britain, and it comprises some 800 members, who have established a court of arbitration for differences amongst members. Like bodies have been formed in other large American cities. In Canada the Dominion Board of Trade consists of the Chambers of Commerce, or Boards of Trade, as they are indifferently called, of the most important cities of the Dominion.

Chambers are private rooms attached to most of the English courts, in which the judges, or more frequently the masters and chief clerks, transact a large amount of judicial business. In fact nearly all business which is begun by what is technically called a *Summons* in England goes to chambers—e.g. all such incidental matters as the recovery of documents, examination of witnesses about to go abroad, investigation of accounts, settling of deeds between parties. A decree of the court which directs further procedure is carried out by a summons to proceed in chambers. Counsel attend in chambers only in important matters. In Scotland a good deal of this business takes the form of a remit to an accountant or other man of business, a judicial reference, a commission to examine witnesses, but all initiated by a motion in court.

Chamber-counsel, a barrister or advocate who gives opinions in his own chambers, but does not, or rarely does, plead in court.

Chambers, EPHRAIM, an amiable but frugal and free-thinking encyclopaedist, was born about 1680 at Kendal, and began life as an apprentice to a globe-maker in London, where he conceived the idea of a cyclopaedia that should surpass Harris's *Lexicon Technicum* (1704). It appeared in 2 folio vols. in 1728, and reached a 6th edition in 1750, Chambers having died meanwhile on 15th May 1750. A French translation gave rise to the more famous *Encyclopédie* of Diderot and D'Alembert; itself expanded into Rees's *Encyclopædia*. Dr Johnson told Boswell that he had partly formed his style upon Chambers's Proposal for his Dictionary. See ENCYCLOPÆDIA.

Chambers, SIR WILLIAM, architect, was born of a Scotch family at Stockholm in 1726, but was brought up in England. At first a sailor, he soon turned to the study of architecture in Italy and at Paris. He rose rapidly, and as early as 1757 was employed by Augusta, Princess-dowager of Wales, to construct the well-known semi-Roman and oriental buildings in Kew Gardens. The king of Sweden made him a knight of the Polar Star. Somerset House (1776) was his design, which Fergusson pronounces 'the greatest architectural work of the reign of George III.' His *Treatise of Civil Architecture* (1759) was successful, but his absurdly pretentious and ignorant *Dissertation on Oriental Gardening* (1772) justly covered him with ridicule. Chambers enjoyed the friendship of Johnson, Reynolds, and Garrick, and died in London, March 8, 1796.

Chambers, WILLIAM, publisher, was born 16th April 1800 at Peebles, his father being a cotton manufacturer there. The boy got a fair elementary education; but owing to the father's misfortunes, his schooling terminated with his thirteenth year. Hence his education for life-work was mainly due to the habit, very early acquired and long maintained, of miscellaneous and extensive reading. The household migrated to Edinburgh in 1813, and next year William was apprenticed to a bookseller. His five years up, he started business in a humble way for himself (May 1819), to bookselling afterwards adding printing. Between 1825 and 1830 he wrote the *Book of Scotland*, and in conjunction with his brother Robert, a *Gazetteer of Scotland*. His experience gained as a bookseller and printer was next utilised in his attempt 'to take advantage of the universal appetite for instruction which at present exists,' and to 'supply that appetite with food of the best kind,' which resulted in the founding of *Chambers's Edinburgh Journal* on 4th February 1832. This was about six weeks in advance of the *Penny Magazine*, and it may be considered the pioneer of that class of cheap and popular periodicals of a wholesome kind now so generally diffused. At the end of the fourteenth number he united with his brother Robert in founding the business of William & Robert Chambers, in which they were associated in writing, editing, printing, and publishing. W. & R. Chambers issued a series of works designed for popular instruction, including besides the *Journal*, *Information for the People*, 2 vols.; the 'Educational Course' series; *Cyclopædia of English Literature*, 2 vols.; *Miscellany of Useful and Entertaining Tracts*, 20 vols.; *Papers for the People*, 12 vols.; and the present *Encyclopædia*, 10 vols. (1859-1868; new edition, 1888-92). In 1849 William acquired the estate of Glenormiston, Peeblesshire, and in 1859 founded and endowed an institution in his native town for purposes of social improvement. Twice elected Lord Provost of Edinburgh, William occupied that office for four years (1865-69), during which he promoted several important public acts, including one for the improvement of the older part of the city, which has resulted in a great diminution of the death-rate. (The death-rate of the city in 1865-75 was 26.26 per 1000; in 1875-85, only 19.94.) He also carried out at his own cost a thorough restoration of St Giles' Cathedral. He died 20th May 1883, having shortly before received the offer of a baronetcy. He was made LL.D. of Edinburgh in 1872. A statue has been erected to his memory in Edinburgh. Besides many contributions to the *Journal*, he was author and editor of various volumes, and wrote *The Youths' Companion and Counsellor*, *History of Peeblesshire* (1864), *Adie Gilroy*, *Stories of Remarkable Persons*, *Stories of Old Families*, and *Historical Sketch of St Giles' Cathedral* (1879).

ROBERT CHAMBERS, born in Peebles, 10th July 1802, took to Latin and books at an early age, and began business as a bookseller in Edinburgh in 1818. His leisure hours were devoted to literary composition, the impulse to which, his brother says, came upon him like an inspiration at nineteen years of age. In 1824 he published the *Traditions of Edinburgh*, the writing of which procured him the friendship of Sir Walter Scott, who furnished some memoranda for the work. Between 1822 and 1834 he wrote in all twenty-five volumes, many of them of great literary interest and permanent historical value. He had already won reputation as an author when he joined his brother after the success of the *Journal* in 1832; and this success was materially promoted by his essays, and by his versatility and elegance as a writer, his diligence in collecting and working up stray

material, and his perception of what was suited to the popular taste in history, poetry, science and arts. In 1844 he published anonymously the remarkable work, *Vestiges of Creation*, which prepared the way for Darwin's great work, *The Origin of Species*. The authorship, positively ascribed to him in the *Athenæum* of 2d December 1854, was first acknowledged in Mr Ireland's introduction to the 12th ed. (1884). He received the degree of LL.D. from St Andrews in 1863. The labour in preparing the *Book of Days* (2 vols. 1863) broke his health, and he died at St Andrews, 17th March 1871. Other works by Robert are *Popular Rhymes of Scotland*, a valuable contribution to folklore (1847), *History of the Rebellions in Scotland*, *Life of James I.*, *Scottish Ballads and Songs* (3 vols. 1829), *Dictionary of Eminent Scotsmen*, *Ancient Sea Margins* (1838), *The Life and Works of Robert Burns* (4 vols. 1851), *Domestic Annals of Scotland* (3 vols. 1859-61), and *Songs of Scotland prior to Burns* (1862). His *Select Writings* (7 vols.) were published in 1847.—His son ROBERT CHAMBERS, born in 1832, became head of the firm in 1883, and conducted the *Journal* till his death, March 23, 1888.—See W. Chambers's *Memoir of William and Robert Chambers* (1872; 13th ed., with supplementary chapter, 1884).

Chambersburg, capital of Franklin county, Pennsylvania, in a pleasant valley 52 miles WSW. of Harrisburg by rail, has several manufactories, breweries, foundries, and machine-shops. A large part of the borough was burned by the Confederates in 1864. Pop. (1880) 6877.

Chambertin, a famous red Burgundy, obtained from a vineyard (62 acres) of that name in the French department of Côte-d'Or, 7 miles S. of Dijon by rail.

Chambéry, capital of the former duchy and present French department of Savoy, beautifully situated between two ridges of hills, amid gardens and country seats, 370 miles SE. of Paris by rail. The scenery around, with the river Laisse flowing through the valley, is exceedingly fine. The town itself, however, is dull and uninteresting, with narrow and gloomy streets winding between high well-built houses. Notable edifices are the small cathedral, the palace of justice, and the old castle of the Dukes of Savoy, restored early in the present century. Chambéry has manufactures of clocks, silk-gauze, soap, hats, paper, and a trade in silk, wine, coal, &c. Pop. (1886) 19,664. From 1525 to 1713 Chambéry was under the dominion of France, and again from the Revolution to 1815, when it was restored to the House of Savoy; but in 1860, by the cession of Savoy, it came again under the rule of France.

Chambeze, the farthest head-stream of the Congo, rises in the highlands south of Tanganyika, about 9° 40' S. lat., and 33° 15' E. long. Its tributaries are large, and form a considerable stream, which flows south-west to Lake Bangweolo (q.v.).

Chambord, a celebrated château in the French department of Loir-et-Cher, stands 12 miles E. of Blois, in the midst of a walled, sandy park of 13,000 acres. Commenced by Francis I. in 1526, it is a huge Renaissance pile, with numberless turrets, chimneys, gables, and cupolas, and with four round towers, each 63 feet in diameter. There are no fewer than 440 rooms. Chambord, the 'Versailles of Touraine,' was a residence of the French kings down to Louis XV., who conferred it on Marshal Saxe; and here in 1670 Molière gave the first representation of his *Bourgeois Gentilhomme*. Among its various occupants were Diane de Poitiers, Stanislaus of Poland, and Marshal Berthier, upon whom it was bestowed by Napoleon in 1809. It was

bought from his widow in 1821 for 1,542,000 francs, and presented to the future Comte de Chambord, who spent large sums on its restoration. He left it to his wife, and, after her, to her nephews, by a will which was more than once disputed, but recognised by the state as valid. See *La Question de Chambord*, by J. B. C. Arnauld (1887).

Chambord, HENRI CHARLES DIEUDONNÉ, COMTE DE, was born in Paris, 29th September 1820, seven months after the assassination of his father, the Duc de Berri (q.v.). On the day of his baptism with water brought by Châteaubriand from the Jordan, the 'Child of Miracle' was presented by the Legitimists with the château of Chambord; hence in 1844 he dropped the title of Duc de Bordeaux for that by which he was most usually known. When Charles X. abdicated at the July revolution of 1830, he did so in favour of his little grandson; but the people insisted on the 'citizen king,' and the elder Bourbons were driven into exile. They fixed their court successively at Holyrood, Prague, and Görz, where the old king died in 1836, and the young count was trained in clerical and absolutist ideas by his aunt, the Duchesse d'Angoulême, and his tutor, the Duc de Damas. A good, dull, timid soul, whom D'Orsay likened to 'a palace with no room furnished but the chapel,' 'Henry V.' had three times a chance of regaining the crown of his ancestors—in 1848, 1870, and 1873, on which last occasion, three months after Thiers's overthrow, he paid an incognito visit to Versailles. Each time he fooled away his opportunities, always vanishing just when his presence was indispensable, and ever protesting that he would 'never abandon the white flag of Joan of Arc.' A fall from his horse (1841) had lamed him for life; his marriage (1846) with the Princess of Modena (1817-86) brought him no successor; and in keeping up a stately mimic court, in stag-hunting from a phaeton, in issuing manifestoes, in visiting innumerable churches, and in much travelling, he passed forty years of blameless inertia. His death, after long suffering, at his castle of Frohsdorf, in Lower Austria, 24th August 1883, was a relief at once to himself and to his adherents. The Comte de Paris inherited his claims. See BOURBON; and the Comte de Falloux' *Mémoires d'un Royaliste* (2 vols. Paris, 1888).

Chambre Ardente ('the fiery chamber'), a name given at different times in France to an extraordinary court of justice, probably on account of the severity of the punishments which it awarded, the most common being that of death by fire. In the year 1535, Francis I. established an Inquisitorial Tribunal and a Chambre Ardente. Both were intended for the extirpation of heresy. The former searched out cases of heresy, and instructed the processes; while the latter both pronounced and executed the final judgment. Under Henri II., the activity of the Chambre Ardente received a new impulse. In 1679 Louis XIV. employed a Chambre Ardente to investigate the numerous reports of poisoning cases which the trial of the Marchioness Brinvilliers (q.v.) caused to be circulated. Many persons of the first rank were examined on suspicion, but no one was executed except the pretended sorcerer, Voisin (1680).

Chambre Introuvable (Fr., 'the chamber the like of which is not to be found again') was the name given to that Chamber of Deputies in France which met after the second return of Louis XVIII. (July 1815), and which, by its fanatical royalty, began to throw the country and society anew into commotion. The name was given to it by the king in his gratitude (though some think even he spoke ironically); but it soon came to be used sarcastically for any ultra-royalist assembly.

Chameleon. See CHAM.ELEON.

Chamfer. In Architecture, an angle which is slightly pared off is said to be chamfered; a large chamfer, as in a wall at the window opening, is called a *splay*. The chamfer is sometimes made slightly concave, in which case it is called a *hollow* chamfer. Chamfers, in Gothic architecture, have frequently ornamental terminations of various kinds. The term chamfer is applied to wood-work as well as stone.

Chamfort, NICOLAS, a famous writer of maxims and anecdotes, was born in Auvergne in 1741. He was of illegitimate birth, and was educated at one of the Paris colleges, where he obtained a scholarship. Having distinguished himself in the prize competitions of the Academy, he gained an entrance into the highest literary circles in Paris, and for some years lived literally 'by his wit, if not by his wits.' At one time Madame Helvétius gave him free lodgings at Sèvres, and he was afterwards made independent by a pension bestowed on him by a now forgotten man of letters named Chabanon. At the Revolution he espoused the popular side, and was hailed in the clubs as 'La Rochefoucauld-Chamfort.' After a time, however, certain incisive witticisms—such as, 'Be my brother or I will kill you,'—drew down on him the anger of the Jacobin leaders. Threatened with arrest, he tried to commit suicide, wounded himself horribly, and died after several days' suffering, 13th April 1794. His writings include tales, dramas, and *éloges* on Molière and La Fontaine—all of little or no worth—a brilliant collection of maxims, and an even more admirable collection of anecdotes. Many of his sayings are among the sharpest and bitterest ever penned—the utterances of a reluctant but sincere cynic, whose insight into human weakness was unusually keen. He has never been excelled as a writer of anecdotes; his work under this head contains a series of portraits in miniature, drawn with the hand of a master, of the Parisian society of his day. Auguis edited his works (5 vols. 1824–25).

Chamier, FREDERIC, an English novelist, born in 1796, entered the navy in 1809, and retiring in 1833, was promoted to be captain in 1856. He had settled near Waltham Abbey, and turned his attention to literary pursuits. Marryat's success in depicting sea-life led Chamier to try the same field, in which he was not without success, though in invention and humour he falls short of his model. His best romances, now almost forgotten, are *Life of a Sailor* (1832), *Ben Brace* (1836), *The Arcturusa* (1837), *Jack Adams* (1838), and *Tom Boulton* (1841). He also wrote a continuation of James's *Naval History* (1837), and a somewhat prejudiced *Review of the French Revolution of 1848* (1849). He died 1st November 1870.

Chamisso, ADELBERT VON, one of the most celebrated of German lyric poets, was born in 1781, at the château of Boncourt, in Champagne. The French Revolution driving his parents to settle in Prussia in 1790, he became in 1796 a page of the queen, and two years later entered the Prussian service. But when the campaign of 1806 broke out he returned to France, for though no admirer of Napoleon, he would not fight against his native land. At this time he was thrown into the circle of Madame de Staël at Coppet, and there began that study of natural science which he afterwards pursued at Berlin. In 1815–18 he accompanied a Russian exploring expedition round the world as naturalist (see CORAL); and on his return was appointed custodian of the Botanical Garden of Berlin. In 1835 he was elected to the Academy of Science; and, after a happy domestic life, he died at Berlin, 21st August 1838, universally loved and honoured. He wrote several works on natural

history, but his fame rests partly on his poetical productions, still more on his quaint and humorous fiction called *Peter Schlemihl* (1813), the story of the man who lost his shadow, which has been translated into almost all the languages of Europe. The character of his poetry is wild and gloomy, and he is fond of rugged and horrible subjects. In his political songs he succeeds well in humour and irony; nor is he deficient in deep and genuine feeling. Indeed, several of his ballads and romances are masterpieces in their way. His collected works have been edited by Hitzig (6th ed. 4 vols. 1874). See his *Life* by Fulda (Leip. 1881).

Chamois (*Antelope* or *Rupicapra*, Ger. *Gemse*), a goat-like species or genus of *Antelope* (q.v.). It inhabits the Alps and other high mountains of Central and Southern Europe, such as the Pyrenees,

Chamois.

the Carpathians, and the mountains of Greece; it is also found on some of the Mediterranean islands, and on the Caucasus, Taurus, and other mountains of the west of Asia. In Europe it is now most numerous on the Bavarian and Styrian Alps. The chamois is about the size of a large goat, but the neck is longer in proportion, and the body shorter; the horns on both sexes are seldom more than six or seven inches long, black, rising nearly straight up from the forehead, and so bent back at the tip as to form a hook. A peculiar gland opens at the base of each horn. The summer colour is reddish brown, with a darker dorsal band, and a yellowish ventral surface; the winter colour is a darker brown, but white below. A dark brown band runs from the eye along each cheek. The rest of the head is pale yellow. The short tail is black.

The usual summer-resort of the chamois is in the higher regions of the mountains, not far from the snow-line, and it is often to be seen lying on the snow. In winter it descends to the higher forests. The aromatic and bitter plants of the mountain-pastures are its favourite food. Young twigs of rhododendron, willow, juniper, &c. are greedily devoured. It is—like the ruminants generally—very fond of salt, and often licks stones for the saltpetre which forms on them. The chamois is gregarious: flocks of one hundred used sometimes to be seen; but in the Swiss Alps, where the numbers have been much reduced by hunting, the flocks generally consist only of a few (4 to 20) individuals. Old males often live solitarily. The female bears one or rarely two young at a birth, in the month of March or April. The general cry of the chamois is a goat-like bleat.

It is an animal of extraordinary agility, and flocks may often be observed sporting in a remarkable manner among the rocky heights. It can leap over ravines 16 to 18 feet broad; a wall 14 feet high presents no hindrance to it; and it passes readily

up or down precipices which almost no other quadruped could attempt. The hunting of the chamois is attended with great hardship and much danger. The hunter sometimes goes out on the adventurous chase alone; but more frequently several go out together, dividing into parties, of which one drives and the other shoots. The scent, sight, and hearing of the chamois are extremely keen. When a flock is feeding, one is always on the watch, and by a sort of whistle, announces apprehended danger. The flesh is highly esteemed. The skin is made into leather, and from it the original *shammy* or *shammy* leather (wash-leather), so much prized for softness and warmth, was obtained, although the name has now become common also to leather prepared from the skins of other animals (see LEATHER and BUFF LEATHER). The horns are often used to adorn alpenstocks. Hairy balls or Concretions (q.v.) found in the stomach used to have a medicinal reputation. When taken young the chamois is easily tamed, and its general disposition is gentle and peaceable. See Keller, *Die Gense* (Klagenfurt, 1885).

Chamomile. See CAMOMILE.

Chamouni, or CHAMONIX (Lat. *Campus munitus*, from the shelter of the mountains), a celebrated valley and village among the French Alps, in the department of Upper Savoy, lying 53 miles ESE. of Geneva, at an elevation of about 3400 feet above the level of the sea. The valley, bounded on the E. by the Col de Balme, is about 13 miles long and 2 broad, and is traversed by the Arve. On the north side lies Mont Brévent and the chain of the Aiguilles Rouges, and on the south, the giant group of Mont Blanc, from which enormous glaciers glide down, even in summer, almost to the bottom of the valley. The chief of these are the Glacier des Bossons, des Bois, de l'Argentière, and du Tour; the Glacier des Bois expands in its upper course into a great mountain-lake of ice called the Mer de Glace. The village of Chamouni owes its origin and its alternative name, Le Prieuré, to the Benedictine convent founded here before 1099. Until 1741, however, the valley was little sought; the region was known, from the savageness of its inhabitants, by the name of Les Montagnes Maudites, or 'accursed mountains.' In that year it was visited by two Englishmen, Pococke and Wyndham, who described it in the Transactions of the Royal Society, but it was only in 1787 that the attention of travellers was effectually called to it by the Genevese naturalist, De Saussure, and others. Since then the number of visitors has gradually increased; now over 15,000 tourists are accommodated annually in the large hotels that have sprung up in the village, where an English chapel was opened in 1860. Grazing and such farming as the elevation allows are carried on, but most of the people are in some fashion dependent on the strangers for their income. Here the best guides are to be found for the neighbouring Alps, and from this point Mont Blanc is usually ascended. At the article ALPS there is a view of Chamouni, whose beauties have been celebrated by Byron, Coleridge, Shelley, Wordsworth, Lamartine, and Ruskin (*Notes and Queries*, July 23, 1887, p. 67). Pop. of village (1886) 576; of commune, 2450.

Champac, or CHUMPAKA (*Michelia Champaca*), an Indian tree (order Magnoliaceæ) possessing great beauty both of foliage and flowers, and venerated both by Brahmanists and Buddhists. Images of Buddha are made of its wood. Its yellow flowers and their sweet oppressive perfume are much celebrated in the poetry of the Hindus. The timber of this and other species is useful and fragrant, and the bark and root are employed in native medicine.

Champagne, a district and ancient province of France, surrounded by Luxemburg, Lorraine, Burgundy, Ile de France, and Orléanais; now forming the departments of Marne, Haute-Marne, Aube, and Ardennes, and parts of Yonne, Aisne, Seine-et-Marne, and Meuse. It was popularly divided into Upper and Lower Champagne and Brie Champenoise, and was fertile in its western, barren in its eastern part. Its chief towns were Troyes, Bar-sur-Aube, Leon, and Rheims. The province was about 180 miles long by 150 broad, its surface presenting extensive plains with ranges of hills, especially in the north and east.

In ancient times Champagne was known as a part of *Gallia Lugdunensis*, was subjugated by Caesar, and afterwards was annexed to the kingdom established by the Franks. After the 11th century it had its own dukes, who were vassals of the French kings. By the marriage of Philip IV. with Joanna, heiress to the kingdom of Navarre, Champagne, and Brie, Champagne in 1284 came to the French crown, and was incorporated in 1328.

Champagne Wine is the produce of vineyards in the above-mentioned province of Champagne. There are white and red champagnes; the white is either sparkling or still. Sparkling or effervescent (*moussure*) champagne is the result of a peculiar treatment during fermentation. In December the wine is racked off, and fined with isinglass, and in March it is bottled and tightly corked. To clear the wine of sediment, the bottles are placed in a sloping position with the necks downward, so that the sediment may be deposited in the necks of the bottles. When this sediment has been poured off, some portion of a *liqueur* (a solution of sugar-candy in cognac with flavouring essences) is added to the wine, and every bottle is filled up with bright clarified wine, and securely re-corked. The fermentation being incomplete when the wine is bottled, the carbonic acid gas generated in a confined space exerts pressure on itself, and it thus remains as a liquid in the wine. When this pressure is removed it expands into gas, and thus communicates the sparkling property to champagne. The effervescence of the wine thus prepared bursts many bottles, in some cases 10 per cent.; and in seasons of early and sudden heat, as many as 20 and 25 per cent. have been burst. Still or non-effervescent champagne is first racked off in the March after the vintage. Creaming or slightly effervescent champagne (*demi-moussure*) has more alcohol, but less carbonic acid gas than sparkling champagne.

The best varieties of this wine are produced at Rheims and Epernay, and generally on a chalky soil. Among white champagnes of the first class, the best are those of Sillery, which are of a fine amber hue, dry, spirituous, and possessing a superior bouquet; those of Ay and Mareuil are less spirituous, but are sparkling, with a pleasant bouquet. Other white wines of first class are those of Hautvilliers, Dizy, and Pierry.

The cellars in which the vintages are stored are cut out of the calcareous rock. The fact that the sale of champagne is very extensive and lucrative, has naturally given rise to adulterations. Spurious champagne is readily manufactured by simply charging other light wines with carbonic acid gas. The popular notions about gooseberry champagne have but small foundation, if any. Gooseberry-juice is far more costly than grape-juice, wherever the grape flourishes, and in this country there are no such great gooseberry plantations as would be required for a flourishing champagne industry, which would demand a few hundred tons of fruit per annum. Recently, the German purveyors have succeeded in preparing light wines—such as Rhenish, Main, Neckar, Meissner, and Naumburg

—so much like genuine champagne, as to deceive even the connoisseur. And much champagne is made on French methods in the United States, not only in California but in some of the Atlantic states. Altogether, it is estimated that the French district produces 1,100,000 hectolitres (24,200,000 gallons) of genuine champagne, of which, however, the finest growths make but a small part.

Champaign, a city of Illinois, 128 miles SSW. of Chicago by rail. It has furniture and wagon factories, a female seminary, and the Illinois Industrial University (1868). Pop. (1881) 5103.

Champaram, a British Indian district in the NW. corner of Behar, with an area of 3531 sq. m.

Champarty, or **CHAMPERTY** (a Norman-French word derived from *campi pars* = the right of the feudal lord to take part of the produce of land cultivated by his tenants), means in English law a bargain whereby the one party is to assist the other in recovering property, and is to share in the proceeds. All such bargains are illegal, and therefore null and void. More particularly an agreement to advance funds, or supply evidence, or professional assistance, for remuneration contingent on success, and proportional to, or to be paid out of property recovered, is illegal; so is a purchase by a solicitor from his client of the subject matter of a pending suit; so is every such purchase, if the real object is only to enable the purchaser to maintain the suit. A man may, however, lawfully sell evidence, and may lawfully purchase an interest in property, though adverse claims exist which make litigation necessary for realising that interest. 'The sale of a mere right to sue is bad, the right to complain of a fraud is not a marketable commodity.' Champarty, as one form of Maintenance (q.v.), was made criminal by various old English statutes, but these are never enforced, and the Criminal Law Commission recommended their repeal. In Scotland there is no law against maintenance and champarty. There is a common-law doctrine against what were in the Roman law called *pacta de quotâ litis*—i.e. purchases of litigations by professional men connected with the suit, who thus had exceptional advantages in making such a contract. But this would not probably be held to strike against an agreement by a non-professional person to advance funds for litigation on terms depending on the result, provided the terms were not extortionate or unconscionable. A Scottish act of 1594 prohibits the purchases of pleas by advocates or agents. In both countries a solicitor can lawfully agree to charge nothing except in event of success; and by recent statute, agreements for the division of profits between town and country agents are made legal. Although there are traces of the law of champarty in the United States, the American law resembles that of Scotland more than that of England. Contracts by solicitors for contingent fees, to the extent even of one-half the property in dispute, have been sustained. In general, however, the American law construes professional contracts as merely giving security for the true worth of the services rendered.

Champfleury, the assumed name of JULES FLEURY-HUSSON, French author, born at Laon, 10th September 1821. In a number of early pieces for the theatre, as well as later romances, he has achieved some distinction as a realistic writer. Works of greater value, however, are those on the history of caricature, of literature, and of art, from 1825 to 1840, and his *Bibliographie Céramique* (1832).

Champion (Low Lat. *campio*, from Low Lat. *campus*, 'a combat,' whence also A.S. *camp*, 'a fight'). In the judicial combats of the middle ages, it was allowed to women, children, and

aged persons, except in cases of high treason or of parricide, to appear in the lists by a representative. Such a hired combatant was called a champion. Those who followed this profession were generally of the lowest class, and were held disreputable (see **BATTLE**, **WAGER OF**). At a later period, in the age of chivalry, the word champion came to have a more dignified acceptance, and signified a knight who entered the lists on behalf of an injured lady, of a child, or of any one incapable of self-defence (see **CHIVALRY**). In England, the crown had its champion, the Champion of England, who, mounted on horseback and armed to the teeth, challenged, at every coronation at Westminster, all who should deny the king to be the lawful sovereign. This office is said by Dugdale to have been conferred by William the Conqueror on Robert de Marmion, with the Lincolnshire manor of Scrivelsby; and by reason of his tenure of that manor, the championship was claimed under Henry IV. by Thomas Dymoke. Henry Lionel Dymoke, who died in 1875, was the nineteenth member of this family who held the office. But the ceremonies of the championship were last exercised at the coronation of George IV. See a series of articles in *Notes and Queries* (1887).

Champlain, a beautiful lake separating the states of New York and Vermont, and penetrating, at its north end, about 6 miles into the Dominion of Canada. Lying 91 feet above sea-level, it is 110 miles long, by from 1 to 15 broad, empties itself into the St Lawrence by the Richelieu River, and has communication by canal with the Hudson. The lake, now an important trade channel, was the scene of several incidents of the French and Indian revolutionary wars; and here a British flotilla was defeated by the Americans, 11th September 1814. It was discovered by Champlain in 1609.

Champlain, SAMUEL DE, French governor of Canada, and founder of Quebec, was born at Brouage in Saintonge in 1567, and in 1603 made his first voyage to Canada. In 1604-7 he was engaged in exploring the coasts, and on his third voyage in 1608 he founded Quebec. In 1612 he was appointed Lieutenant of Canada (under an honorary governor); and the following years were occupied with attacks on the Iroquois, explorations of the interior, and journeys to France, until 1629, when he had to surrender to an English fleet, and was carried captive to England. Liberated in 1632, he returned to Canada in 1633, and died there in 1635. He published several works, reprinted at Quebec, in 4 vols. 1870.

Champlain Period, the name given by Professor Dana to the period succeeding the glacial, and therefore to some extent equivalent to the post-glacial period of English geologists. See **PLEISTOCENE**.

Champollion, JEAN FRANÇOIS, the founder of modern Egyptology, distinguished from his elder brother as 'Champollion the younger,' was born December 23, 1791, at Figeac, in the French department of Lot. He was educated at Grenoble, and devoted himself from his boyhood to the study of oriental languages, especially Coptic. In 1807 he went to Paris to pursue these studies, and in 1816 he became professor of History at the Lyceum of Grenoble. He had already published (1811-14) the first two volumes of a large work entitled *L'Égypte sous les Pharaons* (3 vols.), in which he reproduced, by means of Coptic documents, the national geography of Egypt, when he was expelled from his chair for his Bonapartist sympathies. Comparison of the monuments with the MSS. led him to the conviction that the three systems of Egyptian writing, the hieratic, demotic,

and Hieroglyphic, were essentially one; and that the hieroglyphs were not signs for *ideas*, but for *sounds*. The first results of his labours were published in *De l'Écriture hiéroglyphique des anciens Égyptiens* (1821) and his famous *Lettre à M. Dacier* (1822); and in his *Précis du Système hiéroglyphique* (1824; 2d ed. 1828) he established the conclusion that the hieroglyphs were partly phonetic or alphabetic characters. The final solution by which he arrived at the whole alphabet of twenty-five letters (see **HIEROGLYPHICS**) was pronounced by Niebuhr to be the greatest discovery of the century. Champollion was sent by the king on a scientific mission to Italy in 1824-26, and in 1826 was appointed conservator of the Egyptian collections; and about the same time he published his *Pantheon Égyptien* (1823), with drawings of Egyptian deities from the papyrus-rolls and notes regarding their Egyptian designations, and his *Lettres relatives au Musée royal Égyptien de Turin* (2 vols. 1824-26). In 1828-30 he accompanied a scientific expedition sent to Egypt by the king of France. On his return to Paris he was made a member of the *Académie des Inscriptions* (1830), and a new chair of Egyptology was founded for him in the *Collège de France*. He died March 4, 1832. The MSS. which he left unpublished, extending to more than 2000 pages, were bought by the Royal Library at Paris for 50,000 francs. His posthumous works are *Lettres écrites d'Égypte et de Nubie* (1833; new ed. 1867); *Grammaire Égyptienne*, his principal work (3 vols. 1836-41); *Monuments de l'Égypte et de la Nubie* (5 vols. 1835-45); *Dictionnaire Égyptien en écriture hiéroglyphique* (1842-44); and *Monuments de l'Égypte et de la Nubie* (1844), the last work being afterwards continued and completed under the superintendence of Rouge.

Champollion-Figeac, JEAN JACQUES, an archaeologist, was born 5th October 1778 at Figeac, in the department of Lot. After holding at Grenoble the offices of librarian and professor of Greek, he was appointed in 1828 conservator of MSS. in the Royal Library in Paris; but after the February revolution was deposed from office by Carnot. In 1848 he was appointed librarian of the palace of Fontainebleau. Besides the *Antiquités de Grenoble* (1807) and *Recherches sur les patois de France* (1809), his chief works include the *Annales des Lagides* (2 vols. 1819; supplement, 1821), *Les Tournois du Roi René* (1827-28), and numerous publications of French historical documents. After the death of his younger and more celebrated brother, Champollion-Figeac prepared, with the help of his MSS., *L'Égypte ancienne et moderne* (1840) and *L'écriture démotique égyptienne* (1843), and published a *Notice sur les manuscrits autographes de Champollion le Jeune* (1842). Along with his son, Aimé Champollion-Figeac, he wrote the text to Silvestre's *Palaographie universelle* (4 vols. 1839-41). He died 9th May 1867.

Chance (through the French from Low Lat. *cadentia*), in its original and strict meaning, may be defined as that which determines the course of events, in the absence of law, ordinary causation, or providence. Strictly speaking, it is an idea which few would now be disposed to admit as corresponding to anything which really exists; the religious mind excluding it as inconsistent with the belief in the divine government, and the philosophical mind rejecting it as inconsistent with a recognition of universal laws of causation. As a word, however, it has always been, and always will be popularly accepted; and its use is correct so far as we overlook, or choose for the moment to throw out of view, the more universal connection of events, and regard them as their emergence, on

a superficial view, appears to be determined. It is clear that chance, being only legitimate as an expression in popular parlance, is a term which is much too indefinite to admit of any kind of measurement. What is sometimes called the *Doctrine of Chances* is more properly the *Theory of Probabilities*, and will be dealt with under the head of **PROBABILITY**. For games of chance, see **GAMING**.

Chancel (Lat. *cancellus*, 'a screen'). The chancel, choir, or eastern part of a church was often separated from the nave by a screen of lattice-work, so as to prevent general access thereto, though not to interrupt either sight or sound. As it was in this part of the chancel that the service was always performed previous to the Reformation, the clergy were held to have a special right to it, in return for which its repairs in general still fall on the impropriator, rector, or vicar, and not on the parish. The chief pew in the chancel belongs to the rector or impropriator, but the disposal of the seats in the church, with this exception, belongs to the ordinary, or, practically, to the churchwardens, to whom the authority of the ordinary is delegated. No monument, moreover, can be set up without the ordinary's consent. And where the freehold of the chancel vests in a lay impropriator, nevertheless the right of possession in it for public worship vests in the minister or churchwardens, so that they cannot be excluded from it, nor be charged with trespass for making a door into it from the churchyard. The term chancel is usually confined to parish churches which have no aisles around the choir, or chapels behind it or around it; and in this case the chancel and the choir have the same signification. In small churches which have no constructional chancel, the space within the altar rails is sometimes called by this name, but is more strictly styled the 'sanctuary.' But in larger churches there are sometimes chancels at the ends of the side aisles, and this whether the choir has the character of a choir in the larger sense, or of a chancel. See **CHURCH**.

Chancellor (Lat. *cancellarius*). It is said that the chief notary or scribe of the Roman emperor was called chancellor, either because he was intrusted with the power of obliterating, *cancelling*, or crossing out (*cancellare*, 'to make lattice-work') such expressions in the edicts of the prince as seemed to him to be at variance with the laws, or otherwise erroneous; or (more probably) because he sat *intra cancellos*, within the lattice-work or railings (*cancelli*) which were erected to protect the emperor from the crowding of the people when he sat in judgment. Neither the title nor the office of chancellor is at all peculiar to England. The chancellor of France (Chancelier de France) from a very early time was an officer of state of great power and dignity, under whom several other officers, bearing also the title of chancellor, were employed in the administration of justice and in the defence of the public order. The office was abolished at the Revolution; and though it was restored by the Bourbons, many of the functions of the old chancellor were transferred to the minister of justice, and have ever since been held by him.

In most of the other countries of Europe there are officers of state who bear this or analogous titles, though their powers and duties are very various. In medieval Germany the archbishop and elector of Mainz was Arch-chancellor of the Holy Roman empire, and appointed a Vice-chancellor. The chief functionary in the Austrian empire has often been termed chancellor; and on the reconstitution of the German empire, Prince Bismarck was made 'Chancellor of the Empire' (*Reichskanzler*).

The Russian minister of Foreign Affairs is sometimes called Vice-chancellor. Besides these state-chancellors, there were officers in many other capacities to whom the title was given. Every bishop has his chancellor in the Church of Rome, and there are still chancellors of cathedrals, dioceses, universities, &c.

Chancellor, LORD. It is usually said that the existence of the office in England, as in the other states of Europe, is to be ascribed to the influence which the constitution of the Roman empire had on the constitutions of the modern nations. This influence was exercised in no small measure through the medium of the church, the profession of the law being generally exercised by ecclesiastics; and it is for this reason, probably, that the bishop and the king are furnished with officers bearing the same title, and exercising analogous functions. Soon after the Norman Conquest the English chancellor became a judicial officer of high rank (see CHANCERY), and a confidential adviser of the sovereign in state affairs. Being charged with the supervision of charters and other instruments, he obtained the custody of the great seal. The office of chancellor, or Keeper (q.v.), which in 1576 was declared to be exactly the same, is created without writ or patent, by the mere delivery of the great seal. The chancellor, if a baron, takes precedence of every temporal lord not a member of the royal family, and of all bishops except the Archbishop of Canterbury. To slay the chancellor is treason. The chancellor is a privy-councillor by his office, and prolocutor, or speaker of the House of Lords, by prescription. Though the form in which his tenure of office is terminated is by the resumption of the great seal by the sovereign, the chancellor is now always a cabinet minister, and resigns office with the party to which he is attached. He has the appointment of all justices of the peace throughout the kingdom, but this privilege he exercises generally on the recommendation of the lord-lieutenants. But the most important, and, as it now seems, somewhat anomalous branch of his patronage, arises out of his having been originally an ecclesiastic. Though the last bishop who held the office was John Williams, Archbishop of York, who was Lord Keeper from 1621 to 1625, the chancellor still continues to be patron of a large number of crown livings (though in 1863 about 300 were sold to augment the incomes of those sold and those retained), and visitor of all hospitals and colleges of the king's foundation. As representing the paternal character of the sovereign, again, the chancellor is the general protector of all infants, idiots, and lunatics, and has the supervision of all charitable uses in the kingdom. His jurisdiction 'in lunacy' is committed to him by special delegation from the sovereign. As regards his judicial patronage, the arrangement is, that the chancellor appoints in general all the judges of the superior courts, except the chief-justice, who is nominated by the prime-minister of the day. He also appoints the judges of the county courts, and various subordinate officers. All these functions the chancellor performs in addition to his extensive duties as a judge in the House of Lords, the Privy-council, the Court of Appeal, and the Chancery Division of the High Court of Justice. Objection has often been taken to the combination of judicial and political offices in the same person, but the proposal to appoint a minister of justice has not yet found favour. The salary of the chancellor is £10,000 a year, and he has an annuity of £5000 on retiring from office.

Among the notable Lord Chancellors of England have been Cardinal Wolsey (1515), Sir Thomas

More (1529), Bishop Gardiner (1553), Sir Francis Bacon (1617), Hyde, Earl of Clarendon (1660), Ashley, Earl of Shaftesbury (1672), Lords Jeffreys (1685), Hardwicke (1737), Thurlow (1778), Eldon (1801, 1807), Erskine (1806), Lyndhurst (1827, 1834, 1841), Brougham (1830), Carnworth (1852, 1865), Chelmsford (1858, 1866), Campbell (1859), Westbury (1861), Cairns (1868, 1874), Hatherley (1868), Selborne (1872, 1880), Halsbury (1885), Herschell (1886), Halsbury again (1886). See Lord Campbell's *Lives of the Chancellors* (1845-47).

The office of Chancellor of Scotland, which was analogous to that of England, was abolished at the Union, a keeper of the Great Seal (q.v.) being appointed. The English chancellor is described as Lord High Chancellor of Great Britain and Ireland; but in Scotland he has scarcely any jurisdiction, and in Ireland there is a separate chancellor, whose powers and duties are similar to those of the English chancellor.

CHANCELLOR OF A CATHEDRAL is an officer who formerly had charge of the chapter library, custody of the common seal, superintendence of the choir practices, and headship of the cathedral schools; sometimes being also visitor of all church schools in the diocese. Hence he was often styled *Scholasticus* or *Capischolus* (= *Caput Scholæ*). These functions are now generally in abeyance.

CHANCELLOR OF A DIOCESE is, as legal adviser to the bishop, an ecclesiastical judge, uniting the functions of vicar-general and official principal, appointed to assist the bishop in questions of ecclesiastical law, and hold his courts for him. By an act of Henry VIII. it is provided that he may be a layman, whether married or single, provided he be doctor of the civil law, lawfully create and made in some university. By the canons of 1603 he must be a bachelor of law, at the least, or a master of arts. There are certain cases, however, in which the bishop must sit in person.

For other Chancellors, see UNIVERSITY, EX-CHEQUER, LANCASTER (DUCHY OF).

Chancellor, RICHARD, a daring English seaman, who seems to have been brought up in the household of the father of Sir Philip Sidney, and was chosen in 1553 as captain of the *Bonaventure* and 'pilot-general' of Sir Hugh Willoughby's expedition in search of a North-east Passage to India. The ships were parted in a storm off the Lofoden Islands, and Chancellor, after waiting seven days at Vardöhus, the rendezvous that had been agreed upon, proceeded alone into the White Sea, and travelled thence overland to the court at Moscow, where he was very hospitably treated, and was able to conclude a treaty giving freedom of trade to English ships. His interesting account of Russia was published in Hakluyt's *Navigations*. Next spring Chancellor rejoined his ship and returned to England, where his hopeful reports led to the establishment soon after of the Muscovy Company. In the summer of 1556 he made a second voyage in the *Bonaventure* to the White Sea, and was at Moscow once more in the succeeding winter. In July 1556 he set sail on his voyage homewards, but on 10th November was lost in the wreck of his ship in Aberdour Bay off the Aberdeenshire coast.

Chancellorsville, a post-station of Spottsylvania county, Virginia, near the south bank of the Rappahannock, 11 miles W. of Fredericksburg. In a desperate battle here, May 2 and 3, 1863, General Lee defeated the Federal forces under Hooker. The Confederates, however, suffered a severe loss in Stonewall Jackson (q.v.), who was accidentally wounded by his own men.

Chance-medley and **Chaud-medley** are law expressions, which practically both mean the

same thing, that a particular homicide was justifiable because it was done in the hot blood caused by an unprovoked assault. The phrase has no reference to homicide by accident. See *MAN-SLAUGHTER, SANCTUARY*.

Chancery, the office of a chancellor or ambassador; a place in which writs, &c. are prepared and formally recorded. In England the Chancery was in early times the office in which writs and forms of process were prepared; some of these forms being kept in the Hanaper or hamper, and some in the Petty Bag. When the chancellor became a judicial officer of the first rank, the COURT OF CHANCERY exercised a very wide jurisdiction. The court could not maintain its hold on criminal cases, or on civil cases in which the common-law courts could do adequate justice; but the equitable jurisdiction of the court was established, after a keen struggle with the common lawyers. The assistance of the chancellor, as 'keeper of the king's conscience,' was invoked in cases where the common law might work injustice. A trustee, for example, was in law the owner of the trust property, but the Court of Chancery, which acted *in personam*, would compel him to render an account of his trust to the beneficial owner. This power to enforce equitable claims gave the court an administrative jurisdiction which was used for the protection of infants, married women, mortgagors, &c. The prejudice of the common lawyers against the court was due to the fact that its extensive powers were exercised at the discretion of the chancellor, and not according to settled rules. So late as the time of Charles II., Shaftesbury was thought to be a good chancellor, though he was not a lawyer. A succession of eminent chancellors, from Lord Nottingham to Lord Eldon, developed the rules of equity into a logical system. They did so, it must be admitted, at the expense of unfortunate suitors; and the Court of Chancery became a byword for delay and expense. Some of the evils satirised, and somewhat exaggerated, by Dickens in *Bleak House* (1853) have been removed by modern legislation.

The judges of the Court of Chancery were the Lord Chancellor, the Master of the Rolls (originally a subordinate officer, but afterwards an independent judge), a Vice-chancellor added in 1813, and two more Vice-chancellors added in 1841, when the equity business of the Court of Exchequer was transferred. Two Lords Justices of Appeal were added in 1851. On the passing of the Judicature Acts the inconvenient and indefensible distinction between courts of equity and law was abolished, and the judges of the Court of Chancery became members of the Court of Appeal, or of the Chancery Division of the High Court of Justice.

Among the officers of the Court of Chancery were the *MASTERS IN CHANCERY*, whose office is now abolished, their duties being for the most part assigned to the chief-clerks in the Chancery Division. The office of Accountant-general is also abolished, and Her Majesty's Paymaster-general is charged with the duty of accounting for funds 'in Chancery'—i.e. for cash and stocks standing in the account of any cause or matter before the court. The Pay Office return for 1886 shows the following remarkable figures: Accounts open, 39,944; balance of stocks, &c. (exclusive of foreign securities), £71,946,527; balance of cash, £3,931,054. Under the Chancery Funds Act, 1872, unclaimed balances are transferred to the National Debt Commissioners, but the Consolidated Fund is liable in respect of any claim on these balances under an order of the court.

In various British colonies Courts of Chancery have been established, and the distinction between courts of law and equity has been preserved. But

in the colonies and the United States, as in England, the 'fusion of law and equity' has been effected by legislation. The anomalies of the old system have been removed; but many of the distinctive doctrines and rules of the Court of Chancery remain. In several of the original thirteen states there are distinct Courts of Chancery, but in most of the United States equity powers have been conferred on the higher law-courts, and the principles of equity are administered therein. By the United States constitution and several Acts of Congress, equity powers commensurate with those of the Court of Chancery in England were conferred on the Federal Courts.

The **CHANCERY OFFICE**, in Scotland, is an office in the General Register House at Edinburgh, managed by a director, in which all royal charters of novodamus, patents of dignities, gifts of offices, remissions, legitimations, presentations, commissions, and other writs appointed to pass the Great and Quarter Seals, are recorded. Prior to 1874 a great number of royal charters by progress passed through this office; and this is still done with regard to precepts from Chancery in favour of heirs in crown holdings. It is the duty of the director to keep a record of the decrees of service pronounced in favour of heirs by the Sheriff of Chancery, who holds a special court in Edinburgh for considering such petitions, and to send printed indexes of his record to the sheriff-clerks in the various counties. The record kept by the director also includes the decrees of service pronounced in the different sheriff-courts, and of these the director is bound to furnish extracts. See *GREAT SEAL*.

Chancre. See *SYPHILIS*.

Chanda, chief town of a district of India, on the south-west frontier of the Central Provinces, 90 miles S. of Nagpur. Its stone battlemented walls are $5\frac{1}{2}$ miles round, and 15 to 20 feet high. Pop. (1881) 16,137.

Chandauli, a town of the North-west Provinces of India, 27 miles S. of Moradabad. Pop. (1881) 27,521.

Chanderi, a town of Central India, 105 miles S. of Gwalior. It is now an insignificant place, but its fort and many ruined buildings attest its strength and splendour in former times, when it is said to have contained 14,000 stone houses, 384 markets, 360 caravanserais, and 12,000 mosques.

Chandernagore (properly *Chandan-nagar*, 'city of sandalwood'), a French city, with a scanty territory of about $3\frac{1}{2}$ sq. m., on the right bank of the Hugli, 22 miles above Calcutta by rail. Established in 1673, the place for a while rivalled Calcutta; now, through the gradual silting up of the river, it has lost most of its commercial advantages, and has little external trade. It is the seat of a French sub-governor, with a few soldiers, and has a population of about 23,000, including some 300 Europeans and Eurasians. The town was bombarded and captured by the English in 1757, restored in 1763, twice retaken, and finally restored to the French in 1816.

Chandler, RICHARD, a learned classical archaeologist, was born at Elson, Hants, in 1738, and educated at Winchester and at Queen's and Magdalen colleges, Oxford. His first important work was *Marmora Ozoniensia* (1763), an elaborate description of the Oxford marbles. He afterwards travelled through Greece and Asia Minor, with Revett, architect, and Pars, a painter, at the expense of the Dilettanti Society, to examine and describe the antiquities. The materials collected were given to the world in the following publications: *Ionian Antiquities* (1769), *Inscriptiones Antiquæ* (1774), *Travels in Asia Minor* (1775), and *Travels in Greece*

(1776). Chandler was made D.D. in 1773, and afterwards held preferments in Hants and at Tilehurst, near Reading, in Berks, where he died 9th February 1810.

Chandler, SAMUEL, an English Nonconformist divine, born at Hungerford in 1693, became minister of a Presbyterian church at Peckham, and preached at the Old Jewry from 1726 until his death in 1766. He was an industrious writer, and published especially a large number of works relating to the deist controversy and to catholicism.

Chandor, a town in the province of Bombay, 40 miles N.E. of Nasik. Its fort, commanding an important pass on the route between Khandesh and Bombay, crowns a hill 3994 feet high. It surrendered to the British in 1804, and was finally ceded by Holkar in 1818. Pop. 4892.

Chandos, a great English family, descended from a follower of William the Conqueror, the last representative in the direct male line being Sir John Chandos (died 1428), whose sister married one Giles Brydges. Their descendant, Sir John Brydges, was lieutenant of the Tower under Queen Mary, and was created Baron Chandos in 1554. James Brydges (1673-1744), eighth Lord Chandos, sat in parliament for Hereford from 1698 to 1714, and was created Duke of Chandos in 1719. The lucrative post of paymaster of the forces abroad (1707-12) supplied means for building a palace at Canons, near Edgware, which cost £200,000, but was torn down at the duke's death. Here Handel lived two years, wrote anthems for the chapel service, and produced 'Esther.' In 1796 the title passed by marriage to the family of Grenville, the present dukes of Buckingham and Chandos.

Chandpur, a town of British India, in the North-west Provinces, 19 miles S. of Bijnaur. Pop. 11,182.

Chandragupta. See SANDROCOTTUS.

Changarnier, NICOLAS ANNE THÉODULE, a French general, born at Autun in 1793, was educated at Saint-Cyr, and went in 1830 to Algeria, where for eighteen years he saw all the active service there was to be seen. On the proclamation of the Republic in 1848 he acted as provisional governor-general of Algeria, but returned to Paris to take command of the garrisons of Paris and of the National Guard. He did much to check the outbreaks of the anarchist party during 1849. In the Legislative Assembly he held a sort of neutral position between the Orléanists and the Legitimists, whilst opposing the Bonapartist party. At the *coup d'état* in December 1851, after being imprisoned in Ham, he went into exile till the Franco-Prussian war, when he offered his services to Napoleon III. He was in Metz with Bazaine, and, on its capitulation, retired to Brussels. He returned to France in 1871, entered the Assembly, and assisted M. Thiers in reorganising the army. He died at Versailles, February 14, 1877.

Chang-Chow, a city of China, in the province of Fo-kien, 28 miles W. by S. of Amoy. Pop. estimated at 1,000,000.

Chang-Chow, a city of China, in the province of Kiang-su, about 50 miles E. by S. of Nanking. Pop. 360,000.

Changeling. It was at one time a common belief that infants were sometimes taken from their cradles by fairies, who left instead their own weakly and starveling elves. The children so left were called *changelings*, and were marked by their peevishness, and their backwardness in learning to walk and speak. As it was supposed that the fairies had no power to change children who had been christened, infants were carefully watched until such time as that ceremony had been performed.

This superstition is alluded to by Shakespeare, Spenser, and other poets, and is an essential part of the doctrine of fairy-lore almost everywhere. See Sikes's *British Goblins* (1879).

Chang-Sha, a city of China, capital of the province of Hu-nan, on the Heng-kiang, a tributary of the Yang-tse. Pop. 300,000.

Chank-shell (*Tejanka*), the popular name of the shell of several species of *Turbinella*, a genus of (Prosobranchiate) Gasteropod molluscs, natives

Chank-shell.

of the East Indian seas. These shells (especially *T. rapa* and *T. pyrum*) are obtained chiefly on the coasts of the south of India and Ceylon, and form a considerable article of trade to Calcutta. They are much used as ornaments by Hindu women. A chank-shell opening to the right is rare, and is highly prized in Calcutta, so that a price of £50, or even £100, is sometimes paid for one.

Channel, THE ENGLISH (*La Manche*, 'Sleeve,' of the French, and the *Mare Britannicum* of the Romans), is the narrow sea which, since the glacial period, separates England and France. On the east, it joins the North Sea at the Strait of Dover, where it is narrowest, being only 21 miles wide from Dover to Cape Gris-Nez. From this strait it runs west-south-west for 280 miles, and joins the Atlantic Ocean at the Chops, with a breadth of 100 miles between the Scilly Isles and Ushant Isle. With an average breadth of 70 miles, it is 90 miles wide from Brighton to Havre; 60 miles from Portland Bill to Cape La Hague; 140 miles—its greatest breadth—from Sidmouth to St. Malo; and 100 to 110 miles west of the latter line. It occupies 23,900 square geographical miles, and contains the Channel Isles, Ushant Isle, Isle of Wight, and many islets and rocks, especially off the coast of Brittany. It is shallowest at the Strait of Dover, where a chalk ridge at the depth of twelve to thirty fathoms joins England and France. West of this, the average depth of the central portion is thirty fathoms, with hollows from forty to sixty-two fathoms deep. The English coast-line of the Channel is 390 miles long, and the French coast-line is 570 miles long. Westerly winds prevail, and the current, though imperceptible, is always from west to east. The English Channel abounds in fish, of which the chief are pilchard, mackerel, and oysters. See CHANNEL TUNNEL.

Channel Islands, THE, a group of small islands off the NW. coast of France, which formed part of the old duchy of Normandy, and has remained subject to the British crown. The nearest points are about twelve miles from the French coast. The principal islands are four in number—Jersey, Alderney, Sark, and Guernsey (q.v.); amongst the others being the Casquets, Burhou, Brecqhou, Jethou, Herm, the Minquiers, and the Chauseys. The total area is 75 sq. m.; and the total population has dwindled slightly, from 90,739 in 1851 to 87,702 in 1881. Originally a portion of the Continent, they were thinly peopled by the race—probably neolithic—who raised the cromlechs and other monuments of unhewn stone which are con-

mon to Brittany and the islands. This population, which came to be represented by what may be termed the Celtiberian nationality, was gradually isolated by the action of the tides and maritime currents. The Christian religion was introduced into the islands by missionaries from Ireland and from Brittany; and the Gallo-Roman hierarchy was centred at Dol. There is some evidence

of a partial occupation of the islands by Saxon and Danish sea-rovers. Guernsey is named in the Edda, and arms of Viking character have been dug up there. The islands were probably used as depôts in the conquest of Neustria by the Northmen. Some time elapsed after that event, during which they continued subject to Brittany, but in the early part of the 10th century A.D. the Cotentin was added to the duchy of Normandy, and the islands followed in the annexation. The institutions then introduced were those already established on the mainland of Normandy—derived from the Frankish legal system as it existed when the duchy was first separated from the Frank empire by the treaty of St-Clair-sur-Epte (Stubbs's *Const. Hist.* i. § 92). The feudal system, however, was only partially introduced. The parishes did not become manors—as happened in England after the Conquest—nor did the Norman seigneurs make a general practice of residing in the islands. They drew rents as absentee landlords from the allodial proprietors who, willingly or otherwise, accepted their protection. But these did not yield military service; and the island militia, when formed, adopted and preserved, till comparatively recent times, a parochial organisation. The 12th century is the beginning of the authentic history of these singular little communities, and of the ecclesiastical organisation already transferred from the see of Dol to that of Coutances. When Philip Augustus declared the duchy of Normandy forfeit on the ground of the alleged contumacy, as a vassal, of John Lackland, he also pronounced the confiscation of the fiefs of those seigneurs who might adhere to John; some of these then settled in Jersey, where they formed the chief notables and members of such local government as might be in existence. John confirmed and strengthened the privileges of this body, and appointed coroners sworn to watch over the judicial interests of the crown. By degrees the seigneurs ceased to attend the sittings of the states, where the rural population was represented by the constables or mayors of the parishes or communes: these, together with the rectors, became associated with the coroners,

or 'jurats,' as they came to be called; and the whole assembly was presided over by a bailiff, or lieutenant-governor appointed by the crown. There was also a lord-lieutenant, *comes*, or governor, but he was often an absentee. In the process of time this latter post became chiefly titular; the office of lieutenant-governor was separated from that of bailiff, though the two were occasionally held by the same person, and a regular system of judicial and executive administration came into action. From the time of John to that of Henry VI., many attempts were made by France to conquer the islands. Guernsey was held by the French for some years during the 14th century, though finally reconquered by the English with help from Jersey. In 1461 Jersey itself was conquered, and was held by a French governor for about six years, being finally liberated early in the reign of Edward IV. by Sir R. Harleston. Henry VII. carried his repression of the aristocracy into the islands, where he curtailed the feudal jurisdictions and did something for the popularisation of the militia. The Reformation took early and deep root in the Channel Islands, aided by a considerable immigration of exiled Huguenots from the mainland; but the Anglican ritual was not introduced without difficulty. For most of the time the islands continued subject to the spiritual sway of the Bishop of Coutances; but in 1568 Elizabeth attached them to the diocese of Winchester. Other effects of Elizabeth's reign are the foundation of the college (grammar-school) of St Peter Port, in Guernsey, the grant of Sark to the Carterets of Jersey, and the improvement of the Castle of St Helier, in Jersey, which, like the Guernsey 'College,' still bears the name of the virgin queen.

During the reign of Charles I. Guernsey sided for the most part with the English parliament, Jersey with the crown. In the former island, however, Castle Cornet, which commands the harbour, held out for Charles, and was not reduced until after Jersey had been conquered. This took place in 1651. Under the Commonwealth the Channel Islands continued to enjoy their old privileges, being specially excluded from the 'Instrument of Government,' and from the operation of the excise, because not governed by our laws, but by municipal institutions of their own (*Burton's Diary*).

In the reign of Charles II. the Channel Islands were once more threatened by France, and the militia was improved and formed into regiments. The total population of the Channel Islands was then about 25,000; and the chief towns began to increase in importance. The reign of William III. witnessed the famous victory of the British navy at Cape La Hogue, largely due to information conveyed to the admiral by a gentleman of Guernsey. The privilege of neutrality was taken from the inhabitants—to whom it had ceased to be useful—and they entered upon a course of privateering, which made them, in the words of Burke, 'one of the naval powers of the world.'

In 1781, after the French had espoused the cause of the revolted British colonies in America, a semi-official landing took place in Jersey, headed by an adventurer named Macquart, styling himself Baron de Rullecourt. His defeat by Major Pierson, who fell in the engagement, has been rendered famous by Copley's picture in the National Gallery. Since then the chief event has been in Jersey the introduction of elected deputies into the legislature (1856). In the reign of William IV. the militia of the Channel Islands was declared 'Royal.' Queen Victoria visited them in 1849.

The present constitution of the islands is a development of the ancient institutions, slowly modified to meet changes in surrounding circum-

stances. The people, especially in Guernsey and Jersey, adhere to their old speech, a dialect of the ancient *Langue d'oïl*, which was once a literary language. Its best-known monument is the *Roman de Rou de Wace*, a native of Jersey, who wrote in the 12th century. In our own days it has been revived by the late Georges Métivier, who has been called the 'Guernsey Burns.' The late Sir Robert Marett was also the author of many poems written in the Jersey form of the language. The basis of the local law is the *Coutumier de Normandie*, which is *prima facie* evidence of the common law. Besides this, the local states enact statutes of two kinds—their bylaws (called 'ordonnances'), having force for three years without royal assent, and organic statutes, which must be sanctioned by the crown. The French language, in its modern shape, is the official language of the states and of the law-courts; and a French service is held in the parish churches.

The administration, generally speaking, is of the usual two sorts, the executive and the judicial. The principal officer is the general commanding the troops in each bailiwick, of which Jersey is one, and Guernsey, with its dependencies Sark and Alderney, the other. He is called lieutenant-governor, and is appointed in that capacity for five years. The chief civil officer is the bailiff, who presides in the executive and legislative assemblies, represented when absent by a lieutenant-bailiff. In judicial matters the bailiff is also the chief, the superior courts being formed by a quorum of the jurats. In matters of legislation the states are constituted in Jersey of the twelve jurats, twelve rectors, twelve constables, and fourteen deputies; but in Guernsey almost all power has been retained by the royal court. The other crown officers are the attorney-general, the solicitor-general, and the viscount or *prévôt*, who have a right of sitting in the states, but not of voting.

The Channel Islands, as already mentioned, are attached to the diocese of Winchester, but each bailiwick has its own dean. The livings are in the gift of the crown, but are of small value. The administration is, to a great extent, gratuitous: such offices as are not so being paid chiefly out of the local revenues of the crown. These islands have compulsory military service within their own limits—about one-tenth of the population being in the ranks or the reserve of the militia. Their immunities have been fully and frequently recognised, and much loyalty to England is consequently felt. The industry, thrift, and prosperity of the inhabitants have been testified to by recent observers. Their holdings are small, but the agricultural population consists chiefly of yeomen-proprietors who labour with their own hands. The towns are busy and populous, and the houses, both there and on the farms, are large, substantial, and well kept. The taxation is trifling, the customs duties being very light. Living is very cheap. Communication with the ports of the south of England is regular and frequent.

Geology.—Most of the islands are composed of primary or granitic rocks. Alderney is a mass of syenite, with hornblende, porphyry, and occasional sandstone. The structure of Guernsey is hard syenite to the north, and gneiss to the south. The geology of Jersey is more varied, presenting a mixture of metamorphic rocks, conglomerates, and sandstones, with syenites and quartzites. Shale and blown sand are also prevalent. Sark is composed of very hard syenite, with veins of greenstone and felspar. Granite is quarried from all the islands, especially from Guernsey, Herm, and Mont Mado in Jersey, both for home use and for exportation.

The scenery is exquisitely varied and beautiful;

probably in no other area of similar size could be found such a combination of savage rocks and pleasing landscapes.

The climate is agreeable and suitable to invalids. The prevailing winds are from north to north-west. The mean annual rainfall is 35 inches in Guernsey; but the climate is not over moist, the soil being porous, and evaporation rapid. The mean annual temperature of Jersey is 50°·8; of Guernsey, 50°·5, or about 2° warmer than Greenwich. The range of temperature is very moderate; but the climate of Guernsey is rather more equable than that of Jersey. August is the hottest month; February the coldest. Frost and snow are rare. The autumns are very beautiful; and a second summer, called the *Petit Été de Saint Martin*, generally sets in about the 10th of October, and lasts till the middle of December. Flowering plants and shrubs are about a fortnight earlier in the spring than in England. The sunshine averages nearly six hours a day throughout the year.

The produce of the islands is principally agricultural; but horticulture and floriculture are successfully followed—the latter especially in Guernsey. The soil is generally light, deep, and fertile. The system of cultivation is very primitive. The principal manure is seaweed, which is gathered in vast quantities from the shores at certain seasons under strict regulations. Its annual value to Guernsey alone is estimated at £30,000. A great quantity is burned for the manufacture of kelp and iodine.

The land is held in small parcels ranging from five to twenty English acres. The principal crops are potatoes, hay, wheat, turnips, mangel-wurzel, parsnips, and carrots. The Channel Islands are famous for excellent breeds of horned cattle, usually known as 'Alderneys,' though each island has its own speciality (see CATTLE). The other main articles of exportation are granite, fruit, and early potatoes.

There are no good recent books on the Channel Islands. Physical phenomena will be found treated of by Professor Ansted in *The Channel Islands* (1862). Some useful historical information will be found in Le Quesne's *Constitutional History of Jersey* (1856), and Tupper's *History of Guernsey* (1876). See the separate articles on JERSEY and GUERNSEY.

Channel Tunnel. The proposed tunnel under the narrow channel dividing England and France, which countries in very early geological times were united, would be 23 miles long, including land-approaches. It would be made entirely through and within the area of the 'old gray chalk,' or *craye de Rouen*, as designated by French geologists. This bed of chalk extends from shore to shore. It consists of a mixture of 65 per cent. of chalk and 35 per cent. of clay, and is therefore impervious to water; though the experimental works have shown cracks here and there which exude for a time a fresh or brackish water, apparently imprisoned for ages in these small fissures. While the experimental works have been suspended most of these fissures have run themselves dry. The French Tunnel Company, who possess a concession for making a tunnel to the middle of the Channel, and the English Tunnel Company, associated under 'limited liability,' have made many thousand soundings and experiments, and consider it proved that the 'gray chalk' is not only in the same position and of the same thickness and consistency on each side of the Channel, but that no erosion or fault interfering with continuity exists as between the two coasts.

The experimental works, already executed by a headway of 7 feet diameter on the English side, have been extended by the using of a 'boring machine,' from the foot of Shakespeare's Cliff, near Dover,

for a distance of 2200 yards under the sea. The similar work on the French side seaward, from Sangatte, near Calais, is of about the same length. Thus, about a tenth of the whole distance has been successfully experimented; and the opinion

Section of the Bed of the English Channel, showing the proposed tunnel.

of the engineers engaged is that the work presents exceptionally favourable features for cheap and rapid accomplishment. The original estimate, before experiment showed the way through this favourable stratum of 'gray chalk,' was about £10,000,000; now that estimate is only £4,000,000. The proposal is to have two single-line tunnels—which can be multiplied to any extent side by side as traffic might demand—one tunnel ventilating the other, and to work the lines by engines which have been successfully designed and worked experimentally, charged with highly compressed air. In the construction hardly any pumping and no 'timbering' would be required. The machine which bores takes up any modicum of water with the debris it excavates; and every turn of it gives out a portion of the air, which, at a pressure of about 25 lb. to the inch, is its motive force (see the article BORING).

The instruction to the engineers by Sir Edward Watkin, the chairman of the English Tunnel Company, to 'find the "gray chalk" at its outcrop, and never leave it,' would seem to have reduced a work which at one time appeared all but impracticable to the utmost simplicity and ease of completion. The scheme for a railway tunnel was discussed in 1867 and succeeding years. In 1876 a convention for carrying it out was concluded between the British and French governments, and in the same year boring was begun on the French side; but the excavations on the English side were stopped by order of the British government, mainly for military reasons.

Amongst the supporters of such a submarine means of intercourse between England and France have been the late Prince Consort, Mr Cobden, the late and present Lords Derby, the late Lords Beaconsfield and Clarendon, and Mr Gladstone.

The engineers whose names have been associated with various schemes for a Channel Tunnel have been those of Thomé de Gamond and Raoul-duval in France; and William Low, Frederick Bramwell, Francis Brady, John Hawkshaw, and Brunlees in England.

The experiments near Dover have led to the belief that there is a coal-bed under the Channel. The English Channel Tunnel Company had in 1888 already bored to a depth of 950 feet, and proposed going down to 12,000 feet with the view of finding this mineral.

Channing. WILLIAM ELLERY, a great American preacher and writer, was born 7th April 1780, at Newport, Rhode Island. He graduated at

Harvard in 1798, and in 1803 was ordained minister of a Congregational church in Boston, where his sermons soon became famous for their 'fervour, solemnity, and beauty.' Though never a Trinitarian, at first

he had Calvinistic leanings, but gradually drifted towards what is now known as Unitarianism, although the name itself was repugnant to him, and he would gladly have seen liberal theology growing naturally outwards from within the church herself. His famous sermon, preached at the ordination of the Rev. Jared Sparks in 1819, was a fearless and plain definition of the Unitarian position. It involved him in controversy, a thing which he naturally loathed. To the end of his life he preserved a devoutly Christian heart, shrinking with the delicate instinct of a pious nature from everything cold, one-sided, and dogmatic, whether Unitarian or Trinitarian. As late as 1841

he wrote, 'I am little of a Unitarian, have little sympathy with the system of Priestley and Belsham, and stand aloof from all but those who strive and pray for clearer light.' He had sympathy for social and political as well as purely religious progress, advocated temperance and education, and denounced war and slavery with more than his accustomed eloquence. In 1821 he received the title of D.D. from Harvard University, and next year he visited Europe, and made the acquaintance of several great English authors, such as Wordsworth and Coleridge, both of whom were strongly impressed in his favour. Coleridge said of him, 'He has the love of wisdom and the wisdom of love.' Among his most popular works were his *Essay on National Literature*, *Remarks on the Character and Writings of John Milton*, the *Character and Writings of Fénelon*, his essay on *Negro Slavery*, and that on *Self-culture*. Besides these, he wrote a variety of other essays and treatises, all characterised by vigour, eloquence, pure taste, and a lofty tone of moral earnestness. He died October 2, 1842, at Bennington, Vermont. His works were collected before his death in 5 vols. (Boston, 1841), to which a sixth volume was afterwards added. The American Unitarian Association (Boston) has reprinted the whole in a single cheap volume. An interesting memoir of him has been published by his nephew, William Henry Channing (3 vols. Boston, 1848; new ed. 1880). There is also a short Life by Frothingham (1887).

Chansons de Gestes, long narrative poems, dealing with warfare and adventure, which were popular in France during the middle ages. *Gestes*, from the Latin *gesta*, signified, first, the deeds of a hero, and secondly, the account of these deeds; the family to which the hero belonged being spoken of as *gens de geste*. One of these poems, and that the greatest of all, was composed in the 11th century—namely, the *Chanson de Roland*, which is treated of in the article ROLAND. Most of the others were produced in the 12th and 13th centuries, only a few poems to which the name is strictly applicable having been written after the year 1300 A.D. They were mainly the work of *trouvères*, and were carried by wandering minstrels, *jongleurs* and *jongleresses*, from castle to castle, and from town to town. They are distinguished from the later Arthurian romances and from the Romans d'Aventures both by their matter and their form. Their subjects are invariably taken from French history, or from what passed as such, and they are written in verses of ten or

twelve syllables, arranged in *laissez*, or stanzas of irregular length, throughout each of which the same rhyme or assonance is repeated. In his introduction to the *Song of Roland*, M. Génin points out that it is the decasyllabic verse of the Chansons and not the Alexandrine (a form introduced in the 13th century) which is the true epic verse in French literature. A large number of these poems celebrate the exploits of the peers of Charlemagne, and form what is termed the Carolingian cycle, which includes the *Song of Roland*. But while the author of that poem depicts Charlemagne as on the whole a worthy and venerated sovereign, the aim of the later writers is to exalt the vassal nobles at the expense of the emperor, who is invariably presented in an odious or ridiculous light. 'The great emperor,' says M. Gêrusez, 'pays for the misdeeds of his feeble successors; the monarchy of which he remains the representative has been degraded; consequently he is degraded along with it, to the profit of the feudal hero who is opposed to him.' The principal poems of the Carolingian cycle (setting aside the *Song of Roland*) are *Ogier le Danois*, *Renaud de Montauban*, *Raoul de Cambrai*, *Huon de Bordeaux*, *Les Saisnes*, *Doon de Mayence*, *Gérard de Viane*, and *Huques Capet*. *Ogier* is a typical chanson containing more than 13,000 lines, written by Raimbert of Paris in the first half of the 12th century. It tells how the vassal noble Ogier, after vainly seeking reparation for the death of his son, who has been slain by a son of Charlemagne, is pursued by the emperor into Italy and captured after a heroic resistance; how, saved from death by the intervention of Archbishop Turpin, he lives in concealment until the Saracens invade France, and the emperor is forced to implore his aid; how he yields at last to repeated entreaties, frees the land from the heathen, marries a princess, and lives happily to the end of his days. The style of the poem is clear and vigorous, the characters stand out vividly, the narrative interest is considerable, and the hero rivets the sympathy of the reader. The *Voyage du Charlemagne à Constantinople*, which belongs to the same cycle, offers a strong contrast to *Ogier*. It is a mock-heroic piece, full of broad and extravagant pleasantries, and is rather a long fabliau than a true Chanson de Gestes. Among the other chansons which have come to light, the most remarkable are *Garin le Loherain* (ascribed to Jean de Flagy), which takes us back to the times of Charles Martel and Pepin, and describes the feud between the Counts of Metz and the Counts of Boulogne; *Amis et Amiles*, and its sequel *Jourdain de Blaivies*; *Berte aus grans Piés*, one of the most graceful of all; *Gérard de Roussillon*; *Fierabras*; *Aliscans*, which relates the wars of William of Orange with the Saracens; and *Antioche*, which gives a singularly animated account of the siege of Antioch by the crusaders, one of whom is supposed to have written the original version of the poem. The last forms one of the series known as *Le Chevalier au Cygne*, which is concluded with *Baudouin de Sebourg*.

The Chansons de Gestes are not, strictly speaking, epics, though they are frequently described as such. They are rather the material out of which a genuine epic, such as the *Iliad* or the *Nibelungenlied*, might have been wrought had a great poet appeared to extract the gold from the dross and mould—a work of art out of this rich mass of national legend. There has been a natural tendency to overestimate their worth on the part of those by whom they have been exhumed and edited. Their literary merit, however, is incontestable, and their historical interest is very great. They faithfully reflect the beliefs and customs of the ages in which they were written; they abound in

spirited battle-pieces, and contain not a few passages marked by deep and simple pathos. Their plots are somewhat monotonously alike. The strength of their writers does not lie in invention, but in fresh and vivid and sometimes (as in the picture of the sack of the abbey in *Raoul de Cambrai*) terribly realistic descriptions. Their verse is by no means unmelodious, and their style is rich in picturesque and poetical epithets.

After lying in neglect for centuries, the Chansons de Gestes have for the last fifty years been assiduously studied and brought into notice by a band of French and German scholars. Some fifty of them are now in print, a number of these having been edited by the late M. Paulin Paris, a scholar who did more than any one else to promote the study of this department of literature.

See Léon Gautier's *Les Epopees Françaises* (2d ed. 1878); the *Histoire Poétique de Charlemagne*, by G. Paris (1866); C. d'Héricault's *Essai sur l'Origine de l'Épopée Française* (Frankfort, 1880); Génin's introduction to the *Chanson de Roland* (1850); the series, *Les Anciens Poètes de la France*, which MM. Guessard and Michelant began to issue in 1858; and Fauriel's *Épopée Chevaleresque au Moyen Âge*.

Chant, in Music, is the name applied to the short tunes used in the English Church since the Reformation for the psalms and, less properly, the canticles. The adaptation of the form to the structure of the psalms is obvious. Its distinguishing point is that each section is composed of a reciting note of indefinite length, according to the number of words sung to it, followed by a few notes in regular time, called the Mediation or Termination. The tunes were originally derived, as the name indicates, from the Canto Fermo, or Plain Song of the Roman Church, also called Gregorian Tones. These Gregorian tones were preceded by a still earlier form, the Ambrosian Chant, which was the first attempt to systematise the traditional music of the Christian church, carried out by Ambrose, Bishop of Milan, in the 4th century. Of this, next to nothing is now known, the statements of musical historians being founded on slender authority, and curiously at variance. If any fragments still remain in the services of the Roman Church, they cannot be distinguished from the later Gregorian music (see PLAIN SONG, INTONING). There has been a revival in the present day of the old Gregorian chants, which are all 'single,' that is, composed of only two sections, and adapted to a single verse, and have the additional feature of an introductory 'intonation' of two notes before the first reciting note; but many consider these of mainly antiquarian interest. The double chant, adapted to a couple of verses, and hence more suitable for antiphonal singing, dates from the time of the Restoration; and in later days there have been added quadruple chants. The repertory has been enriched by almost every English composer of the last three centuries, famous or obscure. The objectionable 'florid' style has now happily gone out. On the subject of 'pointing' the psalms—i.e. indicating the division of the verses to accord with the chant, there is great diversity of usage, and no authoritative system. The best treatment of the subject, theoretic and practical, from various points of view, will be found in Helmore's *Psalter Noted and Plain Song*, the *Cathedral Psalter*, and Ouseley and Monk's and Oakeley's *Psalters*. The practice of chanting is gaining ground in the Presbyterian and other churches.

Chantenay, a growing western suburb of Nantes (q.v.).

Chantibun, or CHANTABON, a town of Siam, on a river, near the Gulf of Siam, of considerable importance as a commercial port. Pop. 30,000.

Chantilly, a town in the French department of Oise, 26 miles NNE. of Paris. One of the most beautiful places in the vicinity of the capital, and the headquarters of French horse-racing, it attracts immense numbers of visitors. Apart from its natural beauty, it is interesting as the place where the Great Condé spent the last twenty years of his life in the society of Molière, Boileau, Racine, La Fontaine, and Bossuet, and where his cook killed himself, on the occasion of a royal visit, because the fish failed to arrive. His magnificent chateau was pulled down at the Revolution of 1793, but was rebuilt by the Duc d'Angoulême, who bought back the estate in 1872, and who in 1886 presented it to the French Institute, with its priceless art collections, its celebrated stables for 250 horses, and its 16th-century 'Petit Château,' one of the finest specimens of Renaissance architecture in France. The grounds, park, and forest, 6050 acres in area, are of great beauty—truly a princely gift, its value nearly £2,000,000. The manufacture of silk pillow-lace, or *blonde*, so famous in the 18th century, is all but extinct. Pop. (1886) 4139.

Chantrey, SIR FRANCIS LEGATT, an eminent English sculptor, was born at Jorlathorpe, in Derbyshire, on 7th April 1781 (not 1782, as has been generally said). His father, who was a carpenter, and rented a small farm, died when Chantrey was only twelve years of age, leaving the mother in narrow circumstances. The boy was in 1797 apprenticed for seven years to a carver and gilder in Sheffield called Ramsay. It was in these humble circumstances that Chantrey acquired the rudiments of art. He began to model in clay and to draw portraits and landscapes in pencil. His efforts were encouraged by J. R. Smith, the mezzotint engraver: he acquired some local celebrity as a portrait painter, and in 1802 was enabled to cancel his indentures with Ramsay. Soon afterwards he came to London, and studied for a short time in the schools of the Royal Academy, employing himself also in wood-carving. In 1805 he received his first commission for a marble bust, that of the Rev. J. Wilkinson, for the parish church, Sheffield. This was followed by commissions for colossal busts of admirals for Greenwich Hospital; and having in 1807 married a cousin with some property, his early struggles were over. In 1808 he was successful in the competition for the statue of George III. for Guildhall, and during the rest of his life he was largely employed on works of portraiture. The features of the most celebrated men of his time were transcribed by his chisel, and it was in this class of severely realistic work that he most uniformly excelled; though probably his most widely known statue-group is that of the 'Sleeping Children' in Lichfield Cathedral, a subject—its design has been attributed, in error, to Flaxman—in which the real and the ideal seem to meet and blend. His busts include those of James Watt, Wordsworth, and the two very celebrated heads of Sir W. Scott, which he executed in 1820 and 1828. Among his statues are Sir Joseph Banks (1827), Sir John Malcolm (1837), Francis Horner, William Pitt, George IV., and the Duke of Wellington; while his head of Satan and his 'Plenty' designs for Sheaf House, Sheffield, and his 'Penelope' at Woburn, are examples of his rare treatment of ideal and imaginative subjects. In 1816 Chantrey was elected an Associate, in 1818 a Member of the Royal Academy; and in 1835 he was knighted by William IV. Allan Cunningham, the poet, was his secretary and superintendent of works from 1814 till the date of Chantrey's death, 25th November 1841. The sculptor acquired by the practice of his art a fortune of about £150,000; and bequeathed to the Royal Academy, with liberent to his widow, who died in 1875, a sum yielding about £3000

annually, of which the president was to receive £300 and the secretary £50, and the rest was to be devoted to the purchase of works of art executed in Great Britain. Many national acquisitions have already been made by means of this 'Chantry Fund.' See John Holland's *Memorials of Chantry* (1851).

Chantry (Fr. *chanterie*, from *chanter*, 'to sing'), a term applied alike to endowments or benefices to provide for the chanting of masses, and to the chapels in which such masses are celebrated. These endowments were commonly made in the form of testamentary bequests, the object being to insure the erection of a chapel near or over the spot where the testator was buried, and to remunerate the priests for saying masses in it for the repose of his soul, or of the souls of others named in his will. Many such chantry chapels are still to be seen in English parish churches; but they were more common in abbeys and monastic establishments, in which it was deemed a privilege to be buried, and where some such offering to the brotherhood was in a measure the price of sepulture. These chapels, which have generally the tomb of the founder in the middle of them, are separated from the aisles or nave of the church by open screen-work. Sometimes, again, they are separate erections, projecting from the church externally; but in cathedrals and the larger churches they are generally constructed within the church, often between the piers. Many chantries are lavishly enriched with sculpture and tracery of all descriptions, and some of them are adorned with gilding and painting.

Chanzy, ANTOINE EUGÈNE ALFRED, French general, born at Nouart (Ardennes), 18th March 1823, entered the artillery as a private, received a commission in the Zouaves in 1841, and served almost uninterruptedly in Africa till 1870. After the revolution of the 4th September the Government of National Defence appointed him a general of division; in December he was placed at the head of the second Army of the Loire, and resisted the invaders inch by inch with a stubborn valour that won the respect of the Germans and the confidence of his countrymen, and which found a fitting close in the great six days' conflict about Le Mans. He was elected to the National Assembly, and narrowly escaped being shot by the Communists in 1871. In 1873-79 he was governor-general of Algeria. Chosen a life senator in 1875, he was put forward for the presidency in 1879. He was ambassador at St Petersburg in 1879-81, and afterwards commanded the 6th army corps at Châlons, where he died suddenly, 4th January 1883. See Chuquet, *Le Général Chanzy* (1884).

Chaos signified, in the ancient cosmogonies, that vacant infinite space out of which sprang all things that exist. Some poets make it the single original source of all; others mention along with it Gæa, Tartaros, and Eros. By some also only the rough outlines of heaven and earth were supposed to have proceeded from Chaos, while the organisation and perfecting of all things was the work of Eros. Still later cosmogonists, such as Ovid, represent it as that confused, shapeless mass out of which the universe was formed into a *kosmos*, or harmonious order. Hesiod makes Chaos the mother of Erebus and Nox. In Gen. i. 1-2, after God created heaven and earth, the earth was yet 'waste and void (*tōhū va-bōhū*), and darkness was upon the face of the deep' (*tēhōm*, the Chaldean *tiamat*). See ADAM AND EVE.

Chapala, a lake of Mexico, on the high plateau of Jalisco, surrounded by steep, bare mountains. It has an estimated area of 1300 sq. m., contains many islands, and is traversed by the Rio Grande de Santiago.

Chap-books are little stitched tracts written for the people, and sold by chapmen, or travelling pedlars, whose representative Autolycus is so vividly brought before our eyes by Shakespeare in *Winter's Tale*. The literary wares of the chapman were mostly ballads or other broadsides, but he also dealt in these stitched booklets. Popular literature has naturally become scarce on account of the vicissitudes to which it is subject, and few of the older chap-books exist at the present day. Samuel Pepys collected some of considerable interest which he bound in small quarto volumes and lettered *Vulgaria*. Besides these he left four volumes of chap-books of a smaller size which he lettered *Penny Merriments*, *Penny Witticisms*, *Penny Compliments* and *Penny Godlinesses*. The small quarto chap-books are the descendants of the black-letter tracts of Wynkyn de Worde, Copland, and other famous printers, and were probably bought from booksellers as well as from chapmen. With the 18th century came in a much inferior class of literature, which was printed in a smaller size, and forms the bulk of what is known to us now in collections of chap-books. These tracts were printed largely in Aldermar Churchyard, and afterwards in Bow Churchyard, as well as at Northampton, York, Newcastle-on-Tyne, Stokesley, Warrington, Liverpool, Banbury, Aylesbury, Durham, Birmingham, Wolverhampton, Coventry, Whitehaven, Carlisle, Worcester, Penrith, Cirencester, &c., in England; at Edinburgh, Glasgow, Falkirk, Paisley, Dumfries, Kilmarnock, Stirling, &c., in Scotland; and at Dublin. As ballads are frequently reduced versions of romances, so chap-books usually contain vulgarised versions of popular stories. The subjects of the chap-books are very various; first and foremost are the popular tales, such as *Valentine and Orson*, *Fortunatus*, *Reynard the Fox*, *Jack and the Giants*, *Patient Grissel*, *Tom Thumb*, and *Tom Hickathrift*; then come the lives of heroes, historical abridgments, travels, religious treatises, and abstracts of popular books like *Robinson Crusoe* and *Don Quixote*. Besides these there are the more modern inventions of hack writers. Dougal Graham (1724-1779), bellman to the city of Glasgow, was a popular writer who is supposed to have done much to give a special character to Scottish chap-book literature. Motherwell has styled him 'the vulgar Juvenal of his age.' His works were reprinted at Glasgow in 2 vols. in 1883.

The chap-books of the 17th century are valuable as illustrations of manners; but little is to be learned from those of the 18th century, which are altogether of an inferior character. An instance of this may be taken from the story of Dick Whittington. The earliest version of this tale which has come down to us is a small quarto tract entitled 'The Famous and Remarkable History of Sir Richard Whittington, three times Lord Mayor of London, who lived in the time of King Henry the Fifth in the year 1419, with all the remarkable passages, and things of note, which happened in his time: with his Life and Death.' It is without a date, but was probably published about 1670. In this the historical character of the subject is fairly kept up, although the dates are somewhat mixed, and to this the widespread folk-tale of the cat is added. In the later chap-book versions the historical incidents are ruthlessly cut down, and the fictional ones amplified. The three chief points of the story are (1) the poor parentage of the hero, (2) his change of mind at Highgate Hill by reason of hearing Bow Bells, and (3) his good fortune arising from the sale of his cat. Now these are all equally untrue as referring to the historical Whittington, and the second is apparently an invention of the 18th century. In the 17th-century story we learn

that Whittington set out before daybreak on All-Hallows' Day, and before he got as far as Bunhill he heard Bow Bells ring out. Holloway replaced Bunhill in the later versions, and hence arose the myth connected with Whittington Stone on Highgate Hill.

Hannah More's *Repository Tracts*, and afterwards the publications of the Useful Knowledge Society, Chambers's *Miscellany of Tracts*, and the growth of cheap magazines, greatly reduced the popularity of chap-books; but Catnach, a London printer, kept up the supply in the early portion of the 19th century, and even now chap-books are still produced in England and elsewhere.

The influence of chap-books can never have been very great in Britain from the inferiority of their literary character. This has not been the case in other countries, and Mr Wentworth Webster has discovered the curious fact that the Pastorales or Basque dramas owe their origin to the chap-books hawked about the country (see article *BASQUES*). A valuable and standard work on the chap-books of France was published in 1854, entitled *Histoire des Livres Populaires, ou de la Littérature du Colportage*, by M. Ch. Nisard; but little has been done in England for this class of literature. Mr J. O. Halliwell-Phillips printed in 1849 *Notices of Fugitive Tracts and Chap Books and Descriptive Notices of Popular English Histories*; Mr John Ashton published in 1882 a useful work on *Chap-books of the Eighteenth Century*; and five of the most interesting of the old chap-books have been reprinted (1885) by the Villon Society, with introductions by Mr Gomme and Mr H. B. Wheatley. For German chap-books, the reader should consult Karl Simrock, *Die deutschen Volksbücher* (55 parts, Berlin and Frankfurt, 1839-67), and Gotthard Oswald Marbach, *Altdeutsche Volksbücher* (44 vols. Leip. 1838-47).

Chapel (through Fr. from a late Latin *capella*, which, according to Brachet, already in the 7th century had the sense of a chapel, but earlier meant the sanctuary in which was preserved the *cappa* or cope of St Martin, and was next expanded to mean any sanctuary containing relics). The term now signifies a building erected for the purposes of public worship, but not possessing the full privileges and characteristics of a church. In this sense all places of worship erected by dissenters are now called chapels in England, and the term is also applied to supplementary places of worship, even though in connection with the established church—such as parochial chapels, chapels of ease, free chapels, and the like. In former times it was applied either to a domestic oratory, or to a place of worship erected by a private individual or a body corporate. In the latter sense we speak of chapels in colleges. But its earliest signification was that of a separate erection, either within or attached to a large church or cathedral, separately dedicated, and devoted to special services (see *CHANTRY*). Chapels had no burying-ground attached to them, and the sacrament of baptism was not usually administered in them.—The name is also given to a printer's workshop, hence to a union of the workmen in a printing-office—said to be so applied because Caxton set up his press in a chapel at Westminster.

Chapelain, JEAN, a somewhat curious figure in the gallery of French authors, was born in 1595, and died in 1674. He was a learned, industrious writer, who passed for a time as a poet, and was accepted as the dominant authority in the world of French letters between the literary dictatorships of Malherbe and of Boileau. He produced one of the abortive epics which it was the fashion to write during the regency of Mazarin. This work, the

Pucelle, dealt with the story of Joan of Arc, in twenty-four books. Its appearance covered its author with ridicule. Chapelain was gibbeted in the satires of Boileau, and the critic's severity was in this case amply justified by the dullness and grotesque absurdities of the work which he attacked. Chapelain also wrote a number of odes, one of which, composed in honour of Cardinal Richelieu, is not without merit. An edition of part of the *Pucelle* (1 vol. folio) was published in 1656. The last twelve books still remain in manuscript in the Bibliothèque Impériale.

Chapel Royal, in England, consists of a dean, sub-dean, forty-eight chaplains, ten priests in ordinary, and a numerous lay choir, styled gentlemen of the chapel, with a clerk of the closet, and deputy-clerks of the closet, and an organist. The chaplain's duty is preaching, a certain number being appointed beforehand to take duty each month of the year; the liturgical offices are performed by the dean, sub-dean, and priests in ordinary. The establishment is bound to attend the sovereign wherever the court happens to be; but in fact the services of the chapel are confined to London—formerly to the chapel at Whitehall, destroyed by fire after the Restoration, more recently to the small oratory in St James's Palace. The earliest records concerning the Chapel Royal date from the reign of Edward IV.

The CHAPEL ROYAL OF SCOTLAND was an ancient foundation originally located in Stirling Castle, founded by Alexander I., and liberally endowed by his successors. In the reign of Queen Mary the Chapel Royal was transferred to Holyrood House. After the Reformation 'the minister of the king's household' conducted service in it, and the chapel was used as their parish church by the people of the Canongate. It was endowed with the tithes of various churches, and the revenues of the abbey of Dundrennan. During the period of Episcopal church government the Chapel Royal of Holyrood was presided over by a dean, generally one of the bishops, and served by a number of chaplains (see HOLYROOD). After the Revolution the revenues of the Chapel Royal were bestowed on various ministers and chaplains. In accordance with the report of the University Commission issued in 1863 the whole revenues have latterly been taken to augment the income of several professors of divinity, among whom they are divided. The present Dean of the Order of the Thistle is appointed by his commission from the crown the Dean of the Chapel Royal of Scotland. The other members of the chapel are the chaplains in ordinary, six in number, who are appointed during the pleasure of the crown. Neither the dean nor the chaplains receive any of the revenues of the Chapel Royal, which have been all disposed of in the manner stated, and their duties are purely honorary.

Chaperon, a hood or cap worn by knights of the Garter. Such a hood was at one time in general use, but was latterly appropriated to doctors and licentiates in colleges. A person who acts as a guide and protector to a lady at public places is called a chaperon, probably from this particular piece of dress having been used on such occasions. The name was also applied to devices which were placed on the heads of horses at pompous funerals.

Chaplain, originally an ecclesiastic who accompanied an army, and carried the relics of the patron saint (see CHAPEL). It now signifies a clergyman employed to officiate at court, in the household of a nobleman or bishop, in prisons, with troops, and on board ship. Such officials appear first in the palaces of the Byzantine emperors. For the royal chaplains in Britain, see CHAPEL ROYAL. For prison and workhouse chaplains, see PRISON, POOR.

An ARMY CHAPLAIN, in Britain, is a clergyman not having charge of a parish, especially commissioned to do duty with troops. The office, which has existed for many years, was at one time regarded as a saleable perquisite; but the system was reorganised and improved in 1796. The Chaplains' Department, a branch of the Military Department of the War Office, consists of a Chaplain-general, ranking as major-general; 16 Chaplains to the Forces of the first class, ranking as colonels; 10 of the second class, ranking as lieutenant-colonels; 18 of the third class, ranking as majors; and 35 of the fourth class, ranking as captains. Of these, 13 are Roman Catholic and 6 Presbyterian. Their pay, which in the fourth class is 10s. a day, rises to 22s. 6d. in the highest rank, the chaplain-general receiving £1000 a year. Chaplains are sent on active service with the troops, and in peace are allotted to the various military stations. Their duties are to conduct divine service in camp or barracks, officiate at burials, baptisms, and churchings, visit the hospital and barrack-rooms, give religious instruction in the schools, and generally treat the soldiers and their families as though they were their parishioners. Where the number of troops is small, the parish clergyman is appointed acting chaplain, performs these duties, and receives head-money. Soldiers who do not belong to the Church of England are marched to the nearest place of worship belonging to their denomination, and head-money is granted to the minister in charge. In the United States army, regimental chaplains and post-chaplains may be of any of the regular denominations. They mostly have the rank of captain.

NAVY CHAPLAIN. Every large ship in commission has a chaplain. The Navy Estimates provide for above 100 commissioned chaplains, at stipends varying from £219 to £401 per annum. The Chaplain of the Fleet has an income (with allowances) of £759 a year. The chaplains perform divine service at stated times on shipboard, visit the sick sailors, and assist in maintaining moral discipline among the crew. The estimates of 1887-88 included also £3400 for 'allowances to ministers of religion,' besides the salaries of chaplains. In the United States navy, chaplains on the active list are of various relative ranks, from that of lieutenant to that of captain.

Chapman, a trader, but popularly applied in a more limited sense to a dealer in small articles, who travels as a pedlar or attends markets. Our familiar *chap*, 'a fellow,' is a mere shortening of the name, which is derived from A.S. *ceap*, 'trade,' seen in *Chapside*, *Eastcheap*, and in cognate form in *Copenhagen*. See CHAP-BOOK.

Chapman, GEORGE, dramatist and translator of Homer, was born near Hitchin, Hertfordshire, about 1559. He is supposed to have studied at Oxford University, and to have afterwards proceeded to Cambridge. From a passage in his earliest poem, *The Shadow of Night* (1594), it has been somewhat hastily inferred that he served as a volunteer under Sir Francis Vere in the Netherlands. To Lawrence Keymis's *Relation of the Second Voyage to Guiana* (1596) he prefixed a spirited poem, *De Guiana, Carmen Epicum*. His earliest extant play, *The Blind Beggar of Alexandria*, which has little merit, but was very popular, was produced in February 1595-96, and printed in 1598. The excellent comedy, *All Fools*, printed in 1605, was probably produced in 1599; and about this time he wrote other plays, which have perished. In 1598 he completed Marlowe's unfinished poem, *Hero and Leander*. The first of his Homeric translations was *Seven Books of the Iliads of Homer* (1598). It is a translation of books i. ii. vii.-xi., and is

written in rhymed verses of fourteen syllables. The dedicatory epistle to the Earl of Essex admirably illustrates the writer's dignified temper. Later in 1598 he published *Achilles' Shield*, translated from the eighteenth book of the *Iliad*. In this translation he used rhymed verses of ten syllables, the metre that he afterwards employed in his rendering of the *Odyssey*. It was not until 1610 or thereabouts that he published *Homer, Prince of Poets: translated according to the Greek in twelve Books of his Iliads*, with a fine dedicatory epistle in verse to Prince Henry. The complete translation of *The Iliads of Homer, Prince of Poets*, in rhymed verses of fourteen syllables, appeared in 1611. In the Preface to the Reader he states that the last twelve books had been translated in less than fifteen weeks. Having finished the *Iliad*, he set to work on the *Odyssey*, and in 1616 appeared *The Whole Works of Homer, Prince of Poets, in his Iliads and Odysseys*, which was followed (about 1624) by *The Crowne of all Homer's Workes, Batrachomyomachia, or the Battaille of Frogs and Mice: His Hymns and Epigrams*. In spite of all harshnesses, obscurities, and conceits, Chapman's translation of Homer is a noble achievement. He was not a profound scholar, and has often missed the sense where a schoolboy could set him right. But the work is instinct with life, full of heat and energy. By his contemporaries—Jonson, Drayton, Daniel, and the rest—it was applauded, and in later days it has never lacked admirers. Pope acknowledged its merits; Coleridge declared that it was such a poem as Homer might have written if he had lived in England in the time of Elizabeth; Lamb admired it enthusiastically; and Keats wrote a famous sonnet in its praise. While he was busy with his Homeric labours, Chapman was also writing for the stage. He joined Jonson and Marston in the composition of *Eastward Ho* (1605), and in 1606 published a graceful comedy, *The Gentleman Usher*. In 1607 appeared *Bussy d'Ambois: a Tragedie*; and *The Revenge of Bussy d'Ambois* followed in 1613. These tragedies contain much inarticulate bombast intermingled with exalted poetry. Heavy and undramatic though they were, they held the stage for many years by reason of their impassioned earnestness. Two other tragedies, *The Conspiracie and Tragedie of Charles, Duke of Byron* (1608), are also undramatic, but abound in fine poetry. Lamb was of opinion that of all the Elizabethan dramatists Chapman came nearest to Shakespeare 'in the descriptive and didactic, in passages which are less purely dramatic.' Chapman's other plays are *The May Day* (1611), *The Widow's Tears* (1612), and *Cæsar and Pompey* (1631). Two posthumous tragedies, published in 1654, *Alphonsus and Revenge for Honour*, bear his name, but their authorship is uncertain. *The Ball*, a comedy, and *The Tragedie of Chabot* were published in 1639 as the joint work of Chapman and Shirley. Among Chapman's non-dramatic works are *Enthymia Raptus* (1609), *Petrarch's Seven Penitential Psalmes* (1612), *The Divine Poem of Musæus* (1616), and *The Georgicks of Hesiod* (1618). Chapman died in the parish of St Giles's in the Fields, 12th May 1634. Wood describes him 'as a person of reverend aspect, religious and temperate, qualities rarely meeting in a poet.' A complete edition of Chapman's works in 3 vols., with an essay by A. C. Swinburne, appeared in 1873-75.

Chapone, HESTER, authoress, daughter of Thomas Mulso, was born at Twywell, Northamptonshire, 27th October 1727. She wrote a short romance in her tenth year, and after her mother's death her attention was divided between household duties and the study of French, Italian, Latin, music, and drawing. She wrote for the *Rambler* (No. 10), *Adventurer*, and *Gentleman's*

Magazine, and soon became known to a literary circle, including Richardson; but she is now chiefly remembered by her *Letters on the Improvement of the Mind* (1772), which went through many editions. She married an attorney in 1760, but next year was left a widow; she herself died at Hadley, 25th December 1801. See her *Works with Life* (4 vols. 1807).

Chapped Hands, a form of inflammation of the skin of the back of the hands characterised by abnormal dryness and roughness, with the formation of cracks or fissures. It is caused by exposure to cold, and can generally be prevented or cured by carefully drying the hands after they are washed, and applying glycerine, vaseline, or other simple ointment. The hands should also be protected in cold weather by warm gloves.

Chappell, WILLIAM, F.S.A., the author of the most learned work on ancient English music, was born November 20, 1809. Most of his life he lived in London, where he was for some years a member of a great music publishing house. His first work of importance was *A Collection of National English Airs, consisting of Ancient Song, Ballad, and Dance Tunes* (2 vols. [1838-40]). This work, which contained 245 airs, ultimately grew into the greater and entirely rewritten work, containing over 400 airs, re-harmonised on a consistent plan by Macfarren, *Popular Music of the Olden Time: a Collection of Ancient Songs, Ballads, and Dance Tunes, illustrative of the National Music of England* (2 vols. [1855-59]). The first volume, itself containing 200 airs, forms a complete collection of English airs, so far as known, down to the reign of Charles I.; the second is rather a 'selection', containing, however, all the more interesting or important airs of later date. Mr Chappell took a principal part in the foundation in 1840 of the Musical Antiquarian Society and the Percy Society, and edited some of Dowland's songs for the former and several rare collections for the latter. He published a few papers in the *Archæologia*, contributed invaluable notes to Hales and Furnivall's reprint of the *Perry Folio MS.* (1867-68), and annotated the first three volumes (1869-79) of the Ballad Society edition of *The Roxburghe Ballads* (continued by his friend Mr Elsworth). Mr Chappell published in 1874 the first volume of a *History of Music*. He died in London, 20th August 1888.

Chapra, a town in Bengal, on the Gogra, 1 mile above its confluence with the Ganges. It is capital of the district of Saran. Pop. (1881) 51,670.

Chaptal, JEAN ANTOINE, COMTE DE CHANTELOUP, French statesman and chemist, was born at Nogaret, Lozère, 4th June 1756, and studied at Montpellier, where in 1781 the states of Languedoc founded for him a chair of Chemistry. A considerable fortune left him by his uncle he devoted to the establishment of works for the manufacture of mineral acids, alum, soda, &c. He was made a member of the Institute in 1798, and in 1800 Minister of the Interior. He resigned in 1804, but in 1811 was made a count by the emperor. During the Hundred Days he was a minister of state and director of commerce and manufactures; after the Restoration he withdrew into private life, but was admitted to the chamber of peers by Louis XVIII. in 1819. He died in Paris, 30th July 1832.

Chapter. See *BIBLE*, Vol. II. p. 126.

Chapter-house (Fr. *salle capitulaire*), the building in which the monks and canons of monastic establishments, and the dean and prebendaries of cathedral and collegiate churches, meet for the management of the affairs of their order or society (see *CATHEDRAL*). Chapter-houses frequently exhibit the most elaborate architectural adornment.

as, for example, those of York, Southwell, and Wells. The original stained-glass windows remain at York, and are of exquisite beauty. On the walls of that of Westminster the original painting has been discovered. Chapter-houses are of various forms: those at York and Westminster are octagonal; those at Oxford, Exeter, Canterbury,

Chapter-house, York.

Gloucester, &c. are parallelograms; Lichfield is an oblong octagon; Lincoln, a decagon; and Worcester a circle. In France the chapter-house is generally square. They are always contiguous to the church, and are not generally placed to the west of the transepts. They sometimes open into the church, or are entered by a passage, but are more frequently in connection with the cloisters. In some instances there are arches or windows between the chapter-house and the cloisters to enable those standing in the latter to hear what goes on in the chapter-house. A stone seat on a raised step generally runs round the apartment. Chapter-houses were often used as places of sepulture, and have sometimes crypts under them, as at Wells and Westminster.

Chapul'tepec, a rock 2 miles SW. of the city of Mexico, rising to a height of 150 feet, and crowned by a castle, which was erected by the Spanish viceroy in 1785 on the site of the palace of Montezuma.

Char, a fish. See CHARR.

Chara. The Characeæ or Stoneworts are a small group of common aquatic plants found growing in large tufts, or even covering large expanses on the bottoms of fresh-water ponds and shallow lakes, brackish or even salt-water lagoons, &c., and of which the systematic position has undergone the most extraordinary and instructive vicissitudes. The early botanists, with K. Bauhin, had no hesitation in describing them as horsetails (*Equisetum*). In 1719 Vaillant proposed for them a separate genus (*Chara*), while Linnaeus, although at first disposed to regard them as *Alga*, as their habitat suggests, decided that the small red male reproductive body must be a stamen, and the larger green female one a pistil, and accordingly placed them as flowering plants among the *Monœcia Monandria*. His pupils

at most ventured to remove these to the *Monandria Monogynia*, while De Jussieu regarded them as a genus of *Naiadaceæ* (q.v.), an order of monocotyledonous aquatics with much reduced flowers. In similar opinions he was followed by De Candolle and other eminent systematists: and it was not until 1851 that a careful re-examination of their structure and mode of reproduction by Thuret finally disproved the phanerogamous view, and established their cryptogamic nature. Since that time the group has attracted great attention, and is now on grounds of peculiar instructiveness, both morphological and physiological, one of the classical forms usually presented to the beginner, not only in cryptogamic botany, but general biology.

Commencing with the vegetative system, we find this apparently consisting of a stem with regular whorls of leaves arising at definite points (nodes) of the stem. The internodes, or distances between these, are at first considerable; but as we approach the apex these are shorter and shorter, and at length we lose sight of them in the crowded terminal bud. The resemblance to a young shoot of *Equisetum* is so far satisfactory, and the mineral incrustation (in some species so abundant as to lead to the substitution of the plant for scouring metal) appears to confirm this. The incrustation, however, is calcareous, not siliceous. Even under microscopic examination we may at first sympathise with the old observers, and seem to see in the stem a multicellular structure, even a cortex; nay, to see under our very eyes the actual circulation of the sap. More careful scrutiny, however, enables us to repeat the work of later and more accurate observers. We see that this movement is not the circulation of the sap in a stem, but a streaming of the protoplasm within what is simply a single enormous cell stretching from one node to the next (see CELL). The apparent cortex is a single

Fig. 1. Shoot of *Chara*.

layer of cells covering this internodal cell; and the whole vegetative structure is unravelled when we roughly dissect out the terminal bud, harden, stain and imbed this in paraffin, and thus cut a fine longitudinal section (fig. 2). An apical cell is seen which continually segments off a lower one; this divides (still

Fig. 2.—Longitudinal Section of the apical bud of *Chara*.

transversely to the axis) into two new ones; and the lower of these henceforth steadily lengthens as the internodal cell, while the upper undergoes repeated division, until a plate of nodal cells is formed. In the simpler family (*Nitella*) the internode thus consists of a single naked cell: in the higher (*Chara*), this is inclosed by the so-called cortex, a layer of smaller cells proceeding from those of the upper and lower nodes;

and itself showing a minor nodal and internodal arrangement. In all cases, from the nodal cells there divide off, parallel to the outer surface of the stem, a new set of apical cells, which proceed, like the parent one, to form the 'leaves,' reproducing, that is to say, the stem structure, until they lose the power of division, and end in a single enlarged vegetative cell. A branch may arise from a new formed apical cell cut off in the axil of the oldest leaf of any whorl, while the so-called roots, which fix the plant in the mud, are simply unicellular hairs, lengthenings produced from the superficial cells of buried nodes.

The apparently very complex and characteristic reproductive organs arise also at the nodes of the stem or leaves, in positions and numbers varying with the species. Commencing with the female (fig. 3a), which arises in the position of a branch,

Fig. 3.—Node, bearing reproductive organs:

a, Mature; b, developing. The upper in each case is the female.

we find this to be obviously a shortened and modified one. Its apical cell forms only an internode and node, then ceases division, and becomes enlarged and filled with a store of starch and other reserve material to form an egg-cell; while the cover or archegonium inclosing this is readily seen to be a mere modification of the familiar cortex. In the male apparatus, or antheridium, the branch structure is further modified: its apical cell similarly remains all but sessile, forming only a short node and internode; but segmentation now begins, thus recalling the behaviour of a nodal cell—with which, in having below it an internodal, and not as in the case of the egg-cell, a nodal cell (fig. 3b), it so far corresponds. Eight quadrant-like cells are formed, but these now segment off new cells in the interior of the spherical mass, and in the growth and development of these the nodal and internodal alternation of ordinary vegetative growth can still be traced. Soon, however, a number of long segmented filaments are developed, and the protoplasm of these undergoes rejuvenescence, and becomes modified into a ciliated spermatozoid. When the reproductive organs are ripe, this archegonium is easily broken, and its filaments spread free in the water; the spermatozooids escape in a myriad, and some reach the egg-cell of the archegonium by means of a small opening, which is left by the all but incomplete upgrowth of the cortical cells which form the wall of the archegonium. After a period of rest, the fertilised ovum germinates, producing, however, not directly a new Chara plant, but a simple filament of cells called a proembryo, of which one cell segments into a node, and the oldest cell of this becomes the growing point of the new plant.

The affinities and systematic position of the group thus still afford ground for discussion, although now within narrower limits than formerly; some systematists regarding them as a somewhat aberrant group of Algae, while others insist on their resemblance to the archegoniate cryptogams (see VEGETABLE KINGDOM). The fruits of what seem to

have been gigantic Characeae (Spirangium) occur from the Carboniferous to the Wealden, and ordinary Characeae are abundant in the Tertiary strata. See Howes' *Biological Atlas*, and Sachs' *Botany*.

Characin'idae. See SALMONIDÆ.

Characteristic. See LOGARITHMS.

Character to Servant. The master is under no legal obligation, either in England or in Scotland, to give a character to his servant, however long, faithfully, or efficiently he may have served him; but, if given, the character must be strictly true, or, at all events, in accordance with the master's belief, otherwise he may be exposed to an action of damages, either by the servant whom he has calumniated, or by a subsequent employer whom he has deceived. If true, however, the fact of its being prejudicial will expose the master to no risk. In order to justify the giving of a bad character, however, it must, in general, be asked for by the servant, as the master is not entitled needlessly to publish the servant's defects. Where asked, it will lie with the servant to prove its falsehood, not with the master to prove its truth. The case of the servant being known by the master to have committed a felony while in his service, is, however, an exception to this rule, as, in a case so extreme, the master is at liberty to warn others against taking him into their employment. Even though strictly true, the character, if prejudicial, must not be more so than the circumstances render necessary. Acts of petty dishonesty, such as are too common among servants, will not warrant the master in branding him as a thief. The safe course, in such a case, is to state the offence, and not to describe it by a general epithet, which may convey an erroneous impression of its magnitude.

It is probable that, partly from thoughtless goodness, and partly from a selfish desire to get rid of a bad servant in the most comfortable manner, false characters are given in favour of servants very much more frequently than to their prejudice. It is desirable that masters and mistresses should have in view that they may render themselves liable in reparation of any damage which can be shown to be the direct result of thus inflicting on a stranger a wrong which is unquestionably within the reach of the law.

By an Act of 1816, personating a master, and thus giving a false character to a servant, or asserting in writing that a servant has been hired, contrary to truth; and any person offering himself as a servant, pretending to have served where he has not served, or producing a false certificate, or altering a certificate, or pretending not to have been in any former service, &c., are offences at common law, punishable on conviction before two justices with a fine of £20.

Charade, or 'syllable-puzzle' as the Germans call it, is an amusement which consists in dividing a word of one or more syllables into its component syllables, or into its component letters, predicating something of each; and then, having reunited the whole, and predicated something of that also, the reader or listener is asked to guess the word. As a specimen of the charade depending upon syllables we adduce the following:

'My first is ploughed for various reasons, and grain is frequently buried in it to little purpose. My second is neither riches nor honours, yet the former would generally be given for it, and the latter are often tasteless without it. My whole applies equally to spring, summer, autumn, and winter; and both fish and flesh, praise and censure, mirth and melancholy, are the better for being in it. *Ans. Sea-son.*'

As a specimen of the second class of charades, we take the following happy example from the French:

Quatre membres font tout mon bien,
Mon dernier vaut mon tout, et mon tout ne vaut rien.

The word is *zero*. It is composed of four letters, of

which the last—viz. *o*, is equal to *zero*, the whole ; zero itself being equal to nothing.

But besides charades of this nature there is another kind rather popular at evening-parties—the *acted* charade, the character of which is entirely dramatic. Half a dozen or so of the company retire to a private apartment, and there agree to select a certain word as the subject of the charade ; let us suppose *Memento*. The next thing done is to take the first syllable, *Me*, and arrange a little scene and dialogue, each member taking a certain part. This being accomplished, the amateur actors return to the drawing-room, and commence their performance, the rest of the company constituting the spectators. Care is taken to mention conspicuously, and yet not obtrusively, in the course of the dialogue, the word *Me*, which is the subject of the scene. On its conclusion, they again retire, and devise a new series of incidents for the word *Men*, and repeat the same process for the final syllable *To*. This being also represented, they retire for a fourth time to contrive the final scene, into which the whole word, *Memento*, must be dexterously introduced at an odd moment when the spectators are thought to be off the scent. The company are then asked to guess the word. In order to the effective performance of a charade of this sort, the actors must possess a good share of inventiveness, self-possession, and ready talk, as the greater portion of the dialogue has to be extemporised.

Charadriidæ, a large family of birds, placed among the so-called *Grallatores*, including about 120 species, distributed throughout the world, and especially frequenting the shores of lakes and rivers. They run and fly with equal success, are often seen in migratory flocks, use simple excavations for nests, and feed, often at night, on worms, insects, molluscs, and amphibians. Plovers (q.v., *Charadrius*), Oyster-catchers (*Haematopus*), Turnstones (*Streptilas*), Crocodile-birds (*Pluvianus*), and Sandpipers (*Egialitis*) are good examples of the family.

Charbon. See ANTHRAX.

Charbon Roux. See CHARCOAL (WOOD).

Charcoal is a term most frequently applied to charred wood, or coal produced by charring wood. Formerly, charcoal was the name for charred sea-coal or mineral coal ; and the word is popularly used for the carbonaceous residue of vegetable, animal, or mineral substances when they have undergone smothered combustion.

ANIMAL CHARCOAL, BONE-BLACK, or IVORY-BLACK, is prepared from bones by heating them in close retorts till they undergo the process of destructive distillation, when combustible gases and water, together with the vapours of various salts of ammonia, and oil, are given off, and bone-black is left in the retort. It is generally reduced to coarse grains from about the size of small peas down to large pin-heads, and is extensively used in the arts for decolourising liquids, such as the syrup of sugar, and solutions of argol (impure cream of tartar) and of the alkaloids, as also in Filters (q.v.) for separating chemical impurities from water. The general mode of using the bone-black is to allow the coloured liquid to percolate through a layer of the charcoal, when all colour is arrested, and the syrup or water runs clear and colourless from under the stratum of charcoal. This power of absorbing colouring matters is also observable in vegetable (peat or wood) charcoal, but not to such an extent as in bone-black. The application of heat to the liquids before filtration greatly facilitates the decolourisation, and where the volume of liquid to be operated upon is not great, the most expeditious method is to boil the liquid and bone-

black together, and then strain through filtering-paper or cloth. The composition of bone-black in 100 parts is 10 of pure charcoal, associated with 90 of earthy salts—i.e. in the proportion of one of pure charcoal in 10 of the commercial bone-black. The power of absorbing colours appears to be due to the porosity of the substance, and is not resident simply in the pure charcoal ; indeed, the earthy matters (principally phosphate of lime and carbonate of lime) can be dissolved out of the bone-black by dilute hydrochloric acid, and the pure charcoal thus obtained only possesses about one-third the decolourising power of the total amount of bone-black it was obtained from. Thus, if 100 parts of ordinary bone-black have the power of arresting the colour from *ten* volumes of a given coloured liquid, then the 10 parts of pure charcoal which can be obtained from the 100 parts of bone-black will be found to decolourise only *three* volumes of the same coloured liquid ; so that it is apparent the earthy matters in the bone-black influence and increase the absorption of the colouring matter, and thus render a given weight of the charcoal of greater commercial value. When syrup of sugar and other liquids have been run through bone-black for some time, the pores of the latter appear to get clogged with the colour, and the clarifying influence ceases, and then the bone-black requires to undergo the process of *revivification*, which consists in reheating it carefully in ovens, or iron pipes inclosed in a furnace, when the absorbed colour is charred, and the bone-black can be of service once again as an arrester of colour. After several re-burnings, the bone-black becomes of very inferior absorptive quality, and is then disposed of for the manufacture of bone-ash and dissolved bones (see BONE MANURES). Bone-black has likewise a great power of absorbing odours, especially those of a disagreeable nature, and can thus be employed to deodorise apartments, clothing, outhouses, &c., or wherever animal matter may be passing into a state of active putrefaction.

WOOD CHARCOAL is the most important, though not the purest kind of Carbon (q.v.). Wood consists of carbon, hydrogen, and oxygen, the last two being in the proportion to form water. When heated in the open air, it burns completely away, with the exception of a small white ash ; but if the supply of air be limited, only the more volatile matters burn away, and most of the carbon remains. This is the principle of the process of charcoal-burning in countries where wood is abundant. Billets of wood are built up vertically in two or three rows into a large conical heap, which is covered over with turf or moistened charcoal-ash, and holes left at the bottom for the air to get in. An open space is also left in the middle of the heap to serve as a flue. The heap is set on fire by putting burning wood into the top of the central opening. The combustion proceeds gradually from the top to the bottom, and from the centre to the outside of the heap ; and as the central portions burn away, fresh wood is continually thrown in at the top, so as to keep the heap quite full. The smoke is thick and white when the process is going on properly ; if it becomes thin, and especially if a blue flame appears, the wood is burning away too fast, and the combustion must be checked by closing the holes at the bottom, or by heaping fresh ashes on the top and sides. As soon as the combustion is completed, the heap is completely covered with turf or ashes, and left to cool for two or three days. It is then taken to pieces, and the portions still hot are cooled by throwing water or sand upon them. It is found that 100 parts of wood yield on the average from 61 to 65 parts by measure, or 24 parts by weight, of charcoal. The charcoal thus prepared

is the best suited for fuel. In England a large quantity of charcoal is obtained in the dry distillation of wood in cast-iron cylinders, for the preparation of crude acetic acid. The charcoal thus prepared is preferable for making gunpowder, but is inferior for other purposes. A peculiar kind of charcoal of a reddish-brown colour, and hence termed *charbon roux* or *red charcoal*, is frequently prepared for the manufacture of the gunpowder used for sporting purposes, by subjecting wood in iron cylinders to the action of superheated steam under a pressure of two atmospheres. Powder made with this charcoal absorbs moisture more rapidly than ordinary gunpowder.

The general properties of wood-charcoal are, that it is black and brittle, and retains the form of the wood from which it is derived; it is insoluble in water, infusible and non-volatile in the most intense heat; its power of condensing gases is noticed under Carbon (q.v.); and from its power of destroying bad smells it has been regarded as possessing considerable antiseptic properties. It is frequently stated that charcoal is a bad conductor of heat, but a good conductor of electricity. These properties depend upon the nature of the charcoal, the lighter wood, such as willow, yielding a porous charcoal, with little power of conducting heat or electricity; while boxwood yields a very compact charcoal, which is a good conductor of heat and electricity, and is admirably adapted for the exhibition of the electric light. Charcoal never consists entirely of pure carbon, the degree of purity varying directly with the temperature at which it is formed; thus, charcoal charred at 480° (249° C.) contains 65 per cent. of carbon, while that charred at 750° (399° C.) contains 80, and that charred at 2730° (1499° C.) contains 96; but the loss of charcoal occasioned by these high temperatures is very great, the percentage yield of charcoal corresponding to these temperatures being 50, 20, and 15.

The uses of wood-charcoal are numerous and extensive. It is very largely employed as a fuel, taking the same place in many countries that coal occupies here. From its being proof against all ordinary chemical agencies, superficial charring is often employed to protect wood from decay, as in the case of fence-posts, of telegraph poles, or of piles which are driven into mud or into the beds of rivers to serve as foundations. With the same design it is not unusual to char the interior of tubs and casks destined to hold liquids. In a finely-divided state it is commonly regarded, as has been already stated, as an antiseptic; and there is no doubt that the offensive effluvia from animal matter in an advanced stage of putrefaction disappear when the putrefying substance is covered with a layer of charcoal; but in reality the decay goes on, without the emission of any odour, till at length the whole of the carbon is dissipated as carbonic acid gas, and the hydrogen as water, while the nitrogen remains as nitric acid. It has been shown that the action consists in a rapid process of oxidation, dependent upon the power which finely-divided charcoal possesses of condensing oxygen. In a finely-divided state, charcoal not only condenses gases to a marvellous extent, but has the power of absorbing colouring matters, bitter principles, &c.; and hence it is of extensive use in the laboratory. From the rapidity of its absorbing action, the use of a respirator filled with charcoal has been suggested to protect the mouth and nostrils in an infected atmosphere; trays of powdered wood-charcoal in dissecting-rooms, in the wards of hospitals, and in situations where putrescent animal matter is present, exert a most beneficial influence in sweetening the atmosphere, by absorbing and decomposing the offensive gases. Charcoal is accordingly valuable in filters, not only

for decolourising purposes, but likewise for assisting in purifying water for domestic use. It is also successfully used to prevent the escape of noxious vapours at the ventilating openings of sewers, as it allows the free passage of air, but condenses the offensive effluvia in its pores, where they are destroyed by a process of oxidation. Besides its employment in the manufacture of gunpowder it has many applications in the arts. In medicine it is at present chiefly used to destroy fetor; for which purpose it is applied in the form of powder or poultice to gangrenous sores, phagedenic ulcers, &c.; it is also largely employed in tooth-powders, as by its mechanical action it removes incrustations, while by its chemical action it destroys fetor of the breath. In indigestion accompanied by much flatulence it may be given in doses of two or three teaspoonfuls suspended in water, or may be administered in the form of charcoal-biscuits (see BISCUITS). Very finely-divided poplar charcoal is regarded as the best for medicinal uses. For the pigments bone-black, ivory-black, and other charcoal blacks, see the article BLACK.

Chard, a municipal borough of Somersetshire, 15 miles SSE. of Taunton by rail. It is a fine old market-town, with manufactures of lace, and a neighbourhood rich in British and Roman remains. Pop. (1881) 2411.

Charente, a considerable river in the west of France, rises in the south-west of the department of Haute-Vienne, and flows first NW., then generally S. and WNW., mainly through the departments of Charente and Charente-Inférieure, to the Bay of Biscay, which it enters opposite the island of Oléron after a very circuitous course of 222 miles.

Charente, a department of France, formed chiefly out of the old province of Angoumois. Area, 2285 sq. m. Pop. (1866) 378,218; (1886) 366,408. It is generally level, with granite offshoots of the Limousin range in the north, and chalk-hills in the south, abounding in marine deposits; and it is watered by the river Charente and its tributaries, with the rivers Vienne and Dronne. The hills are in many places clad with chestnut forests. The climate is generally mild and healthy, and a sixth of the surface is devoted to vines, which flourish in the dry, hot limestone soil. The wines grown are spirituous and fiery in flavour, and are chiefly distilled into brandy, which forms the most important of the exports. Truffles grow abundantly in several parts. The principal manufactures besides brandy are paper, leather, felt, and pottery. Charente is divided into the five arrondissements of Angoulême, Cognac, Ruffec, Barbezieux, and Confolens. Angoulême is the chief town.

Charente-Inférieure, a maritime department of France, formed principally from the former provinces of Saintonge, Aunis, and a small portion of Poitou. The Bay of Biscay washes its western boundary. Area, 2625 sq. m. Pop. (1866) 479,529; (1886) 462,803. It is watered on its boundaries by the Sèvre-Niortaise and the Gironde, and in the centre by the navigable Charente and the coast-stream Seudre. The surface is level; the soil, near the coast protected from the sea by dikes, is mostly chalky and sandy, but very fertile. The commerce is mainly in brandy and sea-salt; the evaporation from the salt-marshes from which the latter is taken renders some parts of the coast very unhealthy. The oyster and pilchard fisheries are important. The chief harbours are those of Rochefort and Tonnay-Charente. La Rochelle is the chief town.

Charenton-le-Pont, a town in the French department of Seine, on the right bank of the

Marne, 4 miles SE. of Paris. The bridge over the river, which is important from a military point of view, is defended by two forts forming a part of the fortifications of Paris. At the other side of the river is the National Lunatic Asylum. Pop. (1872) 7141; (1886) 13,335.

Charge is the exposition of the law made by the judge to the jury, in which he comments on the evidence and instructs the jury as to the application of the law to the facts. Charge is also the exhortation of a bishop or archdeacon to the clergy.

Chargé d'Affaires is a fourth-class diplomatic agent, accredited, not to the sovereign, but to the department for foreign affairs; he also holds his credentials only from the minister. See AMBASSADOR.

Chariot, in ancient times a kind of carriage upon two wheels used both in peace and in war. The Roman form, the *currus*, was entered from behind, was closed in front and uncovered. It was drawn by two, three, or four horses, and carried either one or two persons, both standing. The word *biga* is often applied to a two-horse chariot for battle or for racing; *triga* was a name for a chariot drawn by three horses yoked abreast, of which two drew from the pole; while the *quadriga* was drawn by four horses abreast, the two centre ones (*jugales*) only yoked, the two outside ones (*funales*) being attached by ropes. The last was a form common in the racing chariot of the circus, and in processions. The *currus triumphalis*, in which the Roman generals rode during their triumphal entrance into the city, was a chariot of particular form, being quite round and without any side open, while its panels were richly decorated with carvings in ivory. The Roman writers speak of the use among the Britons and some other foreign nations of war-chariots carrying iron blades or scythes fixed to the end of the pole and axle-tree. The war-chariot of the Homeric heroes (*harma*) was somewhat lighter than the Roman *currus*, being partly formed of open rail-work instead of paneling. The oldest war-chariots of which we read are those of Pharaoh (Exodus, xiv. 7). All the eastern nations used them, and many Assyrian tablets represent heroes, such as Sennacherib or Esarhaddon, riding in triumph at the head of their armies in chariots much heavier but otherwise not unlike the Roman forms of chariots with which we are familiar. Two fine four-wheeled chariots with rich ornamentation in bronze-work were dug up by Dr Petersen in a peat-bog in Jutland in 1881 and 1883, and dated by him a hundred years before Christ. See ASSYRIA.

Charities constitute a marked feature of English life. There are also many excellent institutions in Germany and France. The Deaconess House at Kaiserswerth, founded by Pastor Fliedner, Father Zeller's School at Bengren, near Basel, the Asylum for Poor Neglected Children at Dusseldorf, the Blind School at Ilzack, the Evangelical Asylum for Discharged Male Prisoners at Lintorf, the establishments of Mr J. Bost at Laforce—these with many others recur to the mind, and forcibly testify to the amount of philanthropic work being done on the Continent; while in the United States the splendid medical and kindred benevolent institutions of New York and other great towns bear witness to the sympathy and beneficence of that large-hearted nation. But in no country are so many charities of such wide and far-reaching influence to be found as in Great Britain. Taking as an example London alone, there are no less than 1025 institutions of various kinds. This does not include the different bequests under the control of the opulent city companies, which if counted separately would amount to as

many as 300 more, or the smaller semi-religious missions of which each parish, as a rule, possesses two or three. Of the 1025 charities, 813 have been established in the nineteenth century, and 58 since the year 1879. The oldest institution is St Bartholomew's Hospital, Smithfield, founded in 1123. Next to this comes St Katharine's Hospital, instituted 1145, though the present building was erected in 1827. The educational charities are mostly of ancient origin, and the majority were founded in the 16th century—during the reigns of Edward VI. and Elizabeth; but some of less importance, in the gift of the city companies, for the making of small school grants and so on, are even still older. In the 16th century such well-known institutions as St Paul's School (1509), Christ's Hospital (1553), St Peter's College, Westminster (1560), Merchant Taylors' School (1561), and Sir Roger Cholmley's School, Highgate (1565), were founded. There are upwards of 80 different almshouse buildings connected with the metropolis, affording shelter to more than 2000 inmates. Many are of great age—some indeed, as land rose in value, have been abolished, and the money thus gained devoted to pensions; the oldest are the Salters' Company's Almshouses at Watford, founded in 1454. The hospitals and dispensaries number 135. The longest established are the general institutions; those devoted to special forms of disease are of more recent origin, a remark that applies with additional force to the provident dispensaries. A curious feature is to be noticed in the principal lying-in charities. These were all founded between the years 1749 and 1765. For the missionary societies, see MISSIONS. The institutions for the blind number 29; in the majority of cases, the benefit conferred takes the form of a small annuity or pension. A few of the orphan asylums date their existence from the middle of the last century, but the greater proportion have been founded since 1850. It is to this form of charity that the present generation seems especially prone. Whereas in 1850 there were only 17 institutions of this kind, there are now 58. A great increase has also taken place in the number of convalescent homes, reformatory institutions, night refuges, and societies for the relief of the destitute. Following the example so admirably set at Kaiserswerth, various nursing and philanthropic sisterhoods have been established, and within the last five years no fewer than three prominent charities have been formed to provide poor city children with the means of getting away for a limited period to the country or seaside. Finally, it may be mentioned that the receipts of the metropolitan charities for the year 1887 amounted to upwards of £4,500,000.

See Low's *Handbook to the London Charities* (annual), and Fry's; De Liefde, *The Charities of Europe* (1865); Cammann and Camp, *The Charities of New York* (1868); Kenny, *Legislation with regard to Property given for Charitable Uses* (1880).

CHARITY COMMISSIONERS were first appointed in 1853, under an act for the better administration of charitable trusts. For many years previous to this the subject of the endowed charities had been gradually growing in interest. The old Court of Chancery, with its slow, cumbrous, and ruinously expensive procedure, was felt to be out of date, a new order of things was required, and in especial some investigation into the condition of the charitable funds was needed. By an act dating so far back as 1601 (43 Eliz. chap. 4), the Lord Chancellor was empowered under certain conditions to appoint commissioners of inquiry, but these commissions had fallen into disuse, and action was now taken in the person of the Attorney-general—a method that was at once calculated to give rise to many abuses, and prove infinitely vexatious. The first endeavour

to procure the necessary inquiry was in 1786, when under Mr Gilbert's Act (26 Geo. III. chap. 58) information had been obtained on oath from the parochial clergy, churchwardens, and overseers; but these received no direct authority from the Charity Trustees to make such inquiry, and their knowledge was therefore found to be unreliable and inadequate. According to the returns then made to parliament, the endowed charities amounted to £258,710, 19s. 3d. a year—a sum, as was afterwards shown, greatly below their actual value. In 1812 Mr Lockhart, who was strenuously opposed by the city companies, succeeded in passing an Act (52 Geo. III. chap. 102) which required that particulars of the income, capital, object, and trustees of every existing charity, together with the names of the persons holding the deed of endowment, should be registered with the clerk of the peace for the county within six months of the passing of the act; and a similar provision was made for all future charities. A copy of each registration was also to be enrolled in Chancery. Four years later commenced the memorable investigations with which the name of Lord Brougham is so closely connected. In 1816 he moved for the appointment of a Committee of the House of Commons on the subject, and as a result of its deliberations the Committee recommended that an inquiry into the condition of the endowed charities should be undertaken. The first commission for this purpose was appointed by the crown, under an Act of 1818, and further commissions of inquiry were issued and prosecuted under that and subsequent acts until 1837. In the words of Lord John Russell, these successive inquiries 'destroyed many flagrant abuses, detected the perversion of a large amount of charitable funds, and led the way to those further inquiries and those remedial measures of which we have seen the commencement and the progress, but of which the consummation is yet to come.' As showing the magnitude and extent of these investigations, it may be mentioned that the printed reports occupy no fewer than 38 folio volumes, consisting of some 25,000 pages, describe 28,880 charities with an aggregate income of £1,209,395, and were compiled at a cost of upwards of half a million of money. The result of the wide attention thus drawn to the subject was that in 1853, after much parliamentary and private agitation, the great Charitable Trusts Act, for the public supervision of public endowments, was passed. The powers placed in the hands of the commissioners and inspectors appointed under the act, however, were at first exceedingly limited. Beyond a veto on suits by any one but the Attorney-general, the commissioners had only rights of inquiry, of advice, and of rendering assistance in a few cases where the trustees themselves might desire such aid. The act enabled the Lord Chancellor to appoint two persons to be, jointly with the secretary for the time being, 'the official trustees of charitable funds;' and those officers were constituted in 1854. In 1855 another act empowered the board to apportion parish charities under £30 a year; but in regard to the remodelling of these institutions, or in any way making new schemes for their extended usefulness, its operations were still subordinate, not only to Chancery, but to the county courts. A further act, passed in 1860, for the first time gave the commissioners judicial power over charities of £50 a year, and like power, with the consent of the trustees, over larger charities; but, being judicial, the authority of the commissioners can only be called into operation at the suit of persons interested in each case. The powers formerly exercised by the Court of Chancery still exist in the High Court of Justice, but are very rarely called into execution. Should trustees prove

obstinate, or in other ways refuse to apply for new schemes in relation to their institutions, developing combative tendencies with which the commissioners have a difficulty in dealing, then the aid of the High Court of Justice is invoked. Otherwise the whole administration of charitable endowments, under such conditions as above mentioned, lies in the hands of the Charity Commissioners. Under the jurisdiction thus given various improved schemes have been established, and trustees numbering upwards of 400 annually appointed. By the Act 37 and 38 Vict. chap. 87, the powers previously exercised by the Endowed Schools Commissioners were transferred to the Charity Commissioners for a period of five years, and the two bodies have since been amalgamated. The commissioners have also an important power under the Municipal Corporations Act, 1883, of framing schemes for the application of the property of the corporations dissolved under that act. Since the year 1854 the amount of stock transferred to the official trustees of charitable funds has amounted to £16,139,017 (of which sum £674,212 was handed over in 1887), and £2,853,815 has been retransferred, leaving the total sum held by the trustees at the end of 1886, £13,285,202, divided into 14,729 separate accounts.

THE CHARITY ORGANISATION SOCIETY, founded in 1869, took its rise in a sense of the evil of temporary relief, which manifestly tends to lower the self-dependence of the recipient and to encourage pauperism. Previous to the advent of the society, many attempts had been made to cope successfully with the dangers that attend the bestowal of thoughtless charity. Amongst others, Edward Dennison and Octavia Hill had been especially noticeable for their efforts to raise the condition, both morally and physically, of the struggling poor, and for some time district visiting committees and several societies for the relief of distress through the agency of unpaid almoners had been at work. Attention, too, had been powerfully directed to the method of poor-law administration carried on at Elberfeld and other continental towns. It was felt that some scheme for uniting the charities of London in friendly business sympathy, so as to utilise their efforts more effectively and prevent imposition, was needed. This impression gaining ground may be said to have originated the Charity Organisation Society. The object of the society, as stated in its report, is the improvement of the condition of the poor (1) by bringing about co-operation between the charities and the poor-law, and amongst the charities; (2) by securing due investigation and fitting action in all cases; and (3) by repressing mendicancy. At least one representative committee is formed in each of the poor-law divisions of the metropolis, and the society itself may be said to consist of a federation of those committees, at present numbering forty. Each committee appoints one or more charity agents to act under its instructions, and an important part of their duties is to collect particulars as to the actions of the charities of the district and the relief given by them; to receive applications from persons referred to the office, and to investigate their claims; and to keep up communication with the relieving-officers of the guardians. That there is great need for organisation in the matter of charitable relief is amply evidenced by the fact that the society computes that in London alone from four to seven millions sterling are annually dissipated in indiscriminate almsgiving, thus not only encouraging systematic mendicants and impostors, but recklessly wasting money which, if directed into the right channel, would go far to relieve the poverty and distress that exist.

The number of affiliated or corresponding institu-

tions throughout the three kingdoms is upwards of eighty. A society based on similar lines to the English Charity Organisation Society was founded at Buffalo, U.S., in 1877; and Philadelphia, Brooklyn, Boston, Newport, Detroit, Baltimore, Washington, New York, and many other American towns have since followed the example.

Charity, SISTERS OF. See SISTERHOODS.

Charivari is a French term used to designate a wild tumult and uproar, produced by the beating of pans, kettles, and dishes, mingled with whistling, bawling, groans, and hisses, expressive of displeasure at the person against whom it is directed. Its etymology is obscure; the Germans translate it by *Katzenmusik*, to which in English *Cat's-concert* corresponds. In France, during the middle ages, a charivari was generally raised against persons contracting second nuptials, in which case the widow was specially assailed. On these occasions the participants in it, who were masked, accompanied their hubbub by the singing of satirical and indecent verses, and would not cease till the wedding couple had purchased their peace by ransom. Charivari answers to the English concert upon 'marrow-bones and cleavers,' popularly termed 'rough music,' with which it was customary to attack a married couple who lived in notorious discord. It was also got up against an unequal match, such as where there was great disparity in age between the bride and bridegroom. The charivari or 'shiveree' is not uncommon in the frontier districts of the United States.

Sometimes these customs were of such a licentious and violent character as to require military interference. As early as the 14th century the church was forced to threaten punishment, and even excommunication, against those who participated in them. In more recent times, the charivari, from its suggesting derision, ridicule, and satire, has come to be employed as the name of several satirical journals, the most famous among which is *the CHARIVARI*, which was established in Paris, December 2, 1832. *Punch* (q.v.) is the English Charivari.

Charjui, a Russian town of Central Asia, on the Amu-Daria or Oxus, where the Transcaspian railway between Merv and Bokhara crosses the river by a great bridge opened in 1888.

Charkov. See KHARKOV.

Charlatan, a mountebank, quack-doctor, or empiric, and hence any one who makes loud pretensions to knowledge or skill that he does not possess. The word was introduced in the 16th century from the Italian *ciarlatano*, from *ciarlare*, 'to babble.'

Charlemagne, i.e. Charles the Great, king of the Franks (768-814), and Roman emperor (800-14), was born on 2d April 742, perhaps at Aix-la-Chapelle, and was the eldest son of Pepin the Short, the first Carlovingian (q.v.) king of the Franks, and grandson of Charles Martel. On Pepin's death in 768, Charles and his brother Carloman jointly succeeded to the throne; and by Carloman's death, and the exclusion of both his sons from the throne, the former became sole king in 771. In 772 it was resolved in the Diet at Worms to make war against the Saxons, for the security of the frontiers, which they continually threatened, and for the extension of the Christian religion. Charlemagne advanced as far as the Weser in 772, securing his conquests by castles and garrisons. Pope Adrian I. now called him to his aid against Desiderius, king of the Lombards. Charlemagne had married the daughter of Desiderius, and had sent her back to her father because she bore him no children, and married Hildegarde, daughter of the Swabian duke, Godfrey. Desiderius had sought

revenge by urging the pope to crown the sons of Carloman, and on the pope's refusal had laid waste the papal territory. Charlemagne crossed the Alps from Geneva, with two armies, by the Great St Bernard and Mont Cenis, in 773, and overthrew the kingdom of the Lombards in 774. The Lombard dukes acknowledged him as their king, and he secured the pope's favour by confirming the gift which Pepin had made to the papal see of the exarchate of Ravenna. In 775 he was again employed in the most northerly part of his dominions, reducing the Saxons to subjection; in 776 he suppressed an insurrection in Italy; in 777 he so completed his victory over the Saxons that their nobles generally acknowledged him as their sovereign in an assembly at Paderborn. Being now invited to interpose in the wars of the Arabs and Moors in Spain, he hastened to that country in 778, and added to his dominions the region between the Pyrenees and the Ebro. From Spain he was summoned in haste by a new insurrection of part of the Saxons, who had advanced almost to Cologne, but whom he drove back to the Elbe. In 781 he went to Italy, where the pope crowned his second son, Pepin, king of Italy, and his third son, Louis, a child three years old, king of Aquitaine. The Saxons, once more rising in arms, defeated and destroyed a Frankish army in 782, which Charlemagne, after a new victory, fearfully avenged by causing no fewer than 4500 prisoners to be executed as rebels in a single day. A more general rising of the Saxons followed, but in 783-785 the Frankish monarch succeeded in reducing them completely to subjection, and in persuading their principal chiefs to submit to baptism and to become his faithful vassals. In 788 Bavaria was absorbed in the empire of Charlemagne, an event which brought the Franks into contact with the Avars. They, too, were now subdued, and the Frankish dominions extended to the Raab. The eastern 'mark,' the nucleus of the Austrian empire, was established to defend the frontier in that direction (798).

In 800 Charlemagne undertook an Italian campaign which was attended with the most momentous consequences. Its immediate purpose was to support Pope Leo III. against the rebellious Romans. When Charlemagne, on Christmas Day 800, was worshipping in St Peter's Church, the pope unexpectedly, as it appeared, set a crown upon his head, and, amidst the acclamations of the people, saluted him as Carolus Augustus, emperor of the Romans. Although this added nothing directly to his power, yet it greatly confirmed and increased the respect entertained for him, such was still the lustre of a title with which were associated recollections of all the greatness of the Roman empire. A scheme for the union of the newly revived Western Empire with the Empire of the East by Charlemagne's marriage with Irene (q.v.), the Byzantine empress, failed by reason of Irene's overthrow. The remaining years of his reign were spent in further consolidating his vast empire, which extended from the Ebro to the Elbe. Bishoprics were founded in the Saxon country, many of the Slavs beyond the Elbe were brought into dependence on the empire, and the Eider was recognised as the boundary between the Frankish dominions and Denmark. The empire was divided into districts ruled by counts; counts specially called *markgrafen*, or counts of the marches, defended the frontiers against attack; and the unity of rule was maintained by officers, the *missi dominici*, who were sent out in all directions as the organs of the imperial will. This organisation was promoted also by a great annual military muster and by an annual assemblage of the high officials of the empire. Charlemagne

zealously endeavoured to promote education, agriculture, arts, manufactures, and commerce. He projected great national works, one of which was a canal to connect the Rhine and the Danube; but he deemed nothing beneath his attention which concerned the interests of his empire or of his subjects. He required his subjects to plant certain kinds of fruit-trees, the cultivation of which was thus extended northward in Europe. His own domains were an example of superior cultivation. He had a school in his palace for the sons of his servants. He built sumptuous palaces, particularly at his favourite residences, Aix-la-Chapelle and Ingelheim—for he had no fixed capital—and many churches. Learned men were encouraged to come to his court. He himself possessed an amount of learning unusual in his age; he could speak Latin and read Greek. He attempted to draw up a grammar of his own language. Charlemagne was of more than ordinary stature, and of a noble and commanding presence. He was fond of manly exercises, particularly of hunting. His fame spread to all parts of the world: in 798 Haroun Al-Raschid sent ambassadors to salute him. He enjoyed good health till shortly before his death, 28th January 814. He was buried at Aix-la-Chapelle (q.v.), in a church which he had built there. The greatness of his dynasty terminated with his own life. The rule of Charlemagne was a noble attempt to consolidate order and Christian culture among the nations of the West. It was a mighty task which could have been continued and consummated only by a succession of sovereigns of like energy and sagacity with himself. As his successors were weaklings, his empire fell to pieces; yet in many ways he has had a permanent influence on European history. He established much of what were destined to be the beginnings of a new order. Besides his *Capitulaires* (q.v.), there are extant letters and Latin poems ascribed to him. His life was written in Latin by his secretary, Eginhard (q.v.), the best editions being by Zaffé (1876) and Holder (1882). See E. L. Cutts's *Charlemagne and his Times* (1882); and for the Charlemagne of romance, the article CHANSONS DE GESTES.

Charleroi, a town in the Belgian province of Hainault, on the Sambre, 35 miles S. by E. of Brussels by rail. It carries on considerable manufactures in hardware, glass, woollen-yarn, &c. The district is rich in coal, and the number of smelting-furnaces and nail-factories in the neighbourhood is very great; whilst the huge ironworks of Couillet lie within a mile of the town. The fortifications, begun by the Spaniards in 1666, fell next year into the hands of the French, and were completed by Vauban. After six exchanges of ownership between the French and Spaniards, the Peace of Aix-la-Chapelle (1748) left Charleroi in the possession of Austria. In 1794, after a protracted and desperate resistance, it capitulated to the French, when the fortifications were dismantled. The importance of the place from a strategic point of view became apparent during the campaign of 1815, when, three days before Waterloo, Charleroi was occupied by Napoleon, and the fortifications were restored; but in 1866 they were finally demolished. Pop. (1866) 12,150; (1886) 20,511.

Charles, surnamed **Martel** ('the Hammer'), was the natural son of Pepin of Herstal, mayor of the palace under the last Merovingian kings, and was born about 688. After his father's death in 714, he was chosen as their duke by the Austrasian Franks, and at the close of a struggle with the Neustrian Franks became in 720 undisputed mayor of the palace and real ruler of the Franks, the titular kings being mere puppets in his hands. He had much hard fighting with the Saxons and other

stubborn Teutonic races, as the Alemanni and Bavarians, but his great service to Christendom and to civilisation was that he rolled back the surging tide of Moslem conquest. The Saracens had already taken Bordeaux, overrun the duchy of Aquitania, and advanced to the Loire, when Charles met them between Tours and Poitiers (732), and after a desperate battle, in which their leader, Abd-ur-Rahmān, fell, completely defeated them. This was one of the most important victories in the world's history, and saved western civilisation from hopeless retrogression and ruin. 'But for it,' says Gibbon, 'perhaps the interpretation of the Koran would now be taught in the schools of Oxford, and her pulpits might demonstrate to a circumcised people the sanctity and truth of the revelation of Mahomet.' Charles finished his work by defeating the Saracens again in 737, when they had advanced in the Burgundian territories as far as Lyons, and by driving them out of Languedoc. He died on 22d October 741 at Quiercy on the Oise, in the midst of his victories, his projects, and his greatness, leaving the government of the kingdom to be divided between his two sons—Carloman and Pepin the Short.

Charles I., born at Dunfermline on 19th November 1600, was a sickly child, unable to speak till his fifth year, and so weak in the ankles that till his seventh he had to crawl upon his hands and knees. Except for a stammer, he outgrew both defects, and became a skilled tilter and marksman, as well as an accomplished scholar and a diligent student of theology. He was created Duke of Albany at his baptism, Duke of York in 1605, and Prince of Wales in 1616, four years after the death of his dear brother, Prince Henry, had left him heir to the crown of three kingdoms. The Spanish match had been mooted as early as 1614; but it was not till 17th February 1623 that, with Buckingham, his inseparable friend, Charles started on the romantic incognito journey to Madrid, its objects to win the hand of the Infanta, and to procure the restitution of the Palatinate to his brother-in-law, Frederick. Both he and his father swore to all possible and many impossible concessions to the Catholics, but nothing short of his own conversion would have satisfied the Spanish and papal courts; and on 5th October he landed again in England, eager for rupture with Spain. The nation's joy was speedily dashed by his betrothal to the French princess, Henrietta Maria (1609-69); for the marriage articles pledged him, in violation of solemn engagements to parliament, to permit her and all her domestics the free exercise of the Catholic religion, and to give her the upbringing of their children till the age of thirteen.

On 27th March 1625 Charles succeeded his father, James I.; on 13th June he welcomed his little bright-eyed queen at Dover, having married her by proxy six weeks earlier. Barely a twelvemonth was over when he packed off her troublesome retinue to France—a bishop and 29 priests, with 410 more male and female attendants. Thenceforth their domestic life was a happy one; and during the twelve years following the murder of Buckingham (1592-1628), in whose hands he had been a mere tool, Charles gradually came to yield himself up to her unwise influence, not wholly indeed, but more than to that of Strafford even, or Laud. Little, meddling Laud, made archbishop in 1633, proceeded to war against the dominant Puritanism, to preach passive obedience, and uphold the divine right of kings; whilst great Strafford, from championing the Petition of Right (1628), passed over to the king's service, and entered on that policy of 'Thorough' whose aim was to make his master absolute. Three parliaments were summoned and dissolved in the first four years of the

reign; then for eleven years Charles ruled without one, in its stead with subservient judges and the courts of Star Chamber and High Commission. In 1627 he had blundered into an inglorious French war; but with France he concluded peace in 1629, with Spain in 1630. Peace, economy, and arbitrary taxation were to solve the great problem of his policy—how to get money, yet not account for it. Not that Charles cared for money in itself, or had far-reaching projects of tyranny (he failed to enter into Strafford's scheme). But he had inherited a boundless egoism, and, content with his own petty self, had little sympathy with the dead heroism of the Tudor age, none at all with the nascent ardour of democracy. The extension of the ship-tax to the inland counties was met by Hampden's passive resistance (1637); Laud's attempt to Anglicise the Scottish Church, by the active resistance of the whole northern nation (1639). Once more Charles had to call a parliament: two met in 1640—the Short Parliament, which lasted but three weeks, and the Long, which outlasted Charles.

It met to pronounce Strafford's doom; and, his plot with the army detected, Charles basely sacrificed his loyal servitor, his own kingly word, to fears for the queen's safety: no act weighed heavier on him afterwards. The same signature that sent Strafford to the block gave assent to a second bill by which the existing parliament might not be dissolved without its own consent. That pledge, as extorted by force, Charles purposed to disregard; and during his visit to Edinburgh, in the autumn of 1641, he trusted by lavish concessions to bring over the Scots to his side. Instead, he got entangled in dark suspicions of plotting the murder of the Covenanting lords, of connivance even in the Ulster massacre. Still, his return to London was welcomed with some enthusiasm, and a party was forming in the Commons itself of men who revolted from the sweeping changes that menaced both church and state. Pym's 'Grand Remonstrance' justified their fears, and Charles seemed to justify the 'Grand Remonstrance' by his attempt to arrest the five members (4th January 1642); but that ill-stricken blow was dictated by the knowledge of an impending impeachment of the queen herself. On 22d August he raised the royal standard at Nottingham; and the four years' Civil War commenced, in which, as at Naseby, he showed no lack of physical courage, and which resulted at Naseby in the utter annihilation of his cause (14th June 1645).

No need here to track him through plot and counterplot, with Catholics, Presbyterians, and Sectaries, with the Scots and the Irish, with the parliament and the army; enough, that, quitting his last refuge, Oxford, he surrendered himself on 5th May 1646 to the Scots at Newark, and by them in the following January was handed over to the parliament. His four months' captivity at Holmby House, near Northampton; his seizure, on 3d June, by Cornet Joyce; the three months at Hampton Court; the flight on 11th November; the fresh captivity at Carisbrooke Castle, in the Isle of Wight—these lead up to the 'trial' at Westminster of the 'tyrant, traitor, and murderer, Charles Stuart.' He had drawn the sword, and by the sword he perished, for it was the army, not parliament, that stood at the back of his judges. Charles faced them bravely, and with dignity. Thrice he refused to plead, denying the competence of such a court; and his refusal being treated as a confession, on the third day fifty-five out of seventy-one judges—sixty-four more never were present—affixed their names and seals to his death-warrant; four days later, sentence was pronounced.

No need here to tell the well-known story of his meekness towards his persecutors, of the pathetic

parting from two of his younger children, of his preparation for a holy death; or how, on the morning of the 30th January 1649, he passed to that death on the scaffold in front of Whitehall, with a courage worthy of a very martyr. On the snowy 7th of February they bore the 'white king' to his grave at Windsor in Henry VIII.'s vault; in 1813 the Prince Regent had his leaden coffin opened. Six children survived him—Charles and James, his successors; Mary, Princess of Orange (1631–60); Elizabeth (1635–50); Henry, Duke of Gloucester (1639–60); and Henrietta, Duchess of Orleans (1644–70), the last born ten weeks after Charles's final parting from his queen. At the Restoration Charles II. appointed, on his sole authority, a 'form of prayer, with fasting, for the day of the martyrdom of the Blessed King Charles I.' to be annexed to the Common Prayer-book; with the other 'state-services,' it kept its place there till 1859.

A far stronger man than Charles might scarcely have extricated himself from the difficulties that beset him; true, those difficulties were largely of his own creating. But was he right in abandoning Strafford? should he also have sacrificed wife, faith, and crown? If yes, then was he wholly in the wrong; if no, he was partly—for once at least—in the right. Vices, other than duplicity, he had none, as we use the word. He was vague, vacillating, obstinate; unable to lead or be led; superstitious, heedful of omens; unsympathetic and reserved where he did not love; intolerant of opposition to his will. But he was a good husband, a good father, a good churchman—no man so good was ever so bad a king; no man so fallible believed so honestly in his infallibility. For Charles was honest to his own convictions. His very duplicity was due sometimes to schooling in 'kingscraft,' but oftener to inability to see two sides of a question. Now he saw one, and now the other, but never both sides at once; and, just as he saw, so he spoke. He was not a liar because he loved a lie. Milton's charges against him of 'all manner of lewdness' rank with Milton's charge that he poisoned his father; and Bishop Heber's rash statement that Jeremy Taylor's second wife was 'generally believed to be a natural daughter of Charles, when Prince of Wales,' is backed by no tittle of evidence. Indeed, as a pattern of culture and purity, one prince alone is worthy to be named beside him—the late Prince Consort; and had Charles's lot fallen, like his, on peaceful days of settled monarchy, admiration, not pity, might now be our feeling towards him. But Charles was predestined to sorrow. 'A tragic face!' said the sculptor Bernini, as he looked on the triple portrait by Vandyke; already, the shadow of a violent death overclouded those fine, weak features.

R. Gardiner's *Puritan Revolution* (1876), *History of England, 1603–42* (10 vols. 1863–82; new ed. 1883–84), and *History of the Great Civil War* (vol. i.–ii. 1642–47, 1886–89).

Charles II., born at St James's on 29th May 1630, was present at Edgehill (1642), and in 1646, after a twelvemonth in the western counties, escaped to France by way of Scilly and Jersey. He got little good from two years spent in Paris; then he passed on to Holland, where he met with a better reception, and whence in 1648, with nineteen

English royalist war-ships, he made an expedition to the Thames. His father beheaded—Charles did his utmost to save him, even sending a *carte blanche* to the English parliament—and his hopes disappointed from Ireland and Montrose, in 1650 he accepted the terms of the Scottish commissioners, and landed on 23d June at the mouth of the Spey. That was a dreary time of prayers, fastings, and sermons (six sermons a day) for the gay young prince. Less a king than state-prisoner, he must sign and re-sign the two Covenants, must put away his old friends, must acknowledge the sins of his house, his father's blood-guiltiness and mother's idolatry. But the defeat at Dunbar and his 'start' for the Highlands gained Charles somewhat more liberty; and, having on 1st January 1651 been crowned at Scone, in the following August he suddenly marched, with 10,000 men, into England. Few joined the Scots, and, catching them up at Worcester, Cromwell utterly routed them on 3d September. For six weeks Charles wandered a fugitive, a thousand pounds set on his head, through the western and southern counties, now hiding in the oak at Boscombe, now riding disguised as a serving-man, anon lurking at Stonehenge. More than forty persons were privy to his secret, yet on 15th October he embarked at Shoreham for Normandy. Then followed nearly three years of exile in France, nearly two at Cologne, then three in the Low Countries, needy everywhere, everywhere profligate; but at last, on 26th May 1660, Charles landed at Dover, recalled to the throne by the fall of the Protectorate, and the nation's dread of military despotism. 'It must be my own fault,' he jested, 'that I did not come sooner back, for I find no one but tells me he has always longed for my home-coming.'

Of the four parliaments that succeeded the Convention, the first or 'Cavalier' parliament lasted through nearly two-thirds of the entire reign, from May 1661 to January 1679; from March 1681 Charles ruled without one. The first seven years (1660-67) were the period of Clarendon's ascendancy, of constitutional loyalty to church and state, as anti-Catholic as it was anti-Puritan. Next came the Catholic-Presbyterian Cabal, broken up by the Test Act of 1673; and then the fierce struggle between the Court and Country factions, in which Shaftesbury played the chief part, and from which, in the end, Charles issued victorious.

As early as 1661 he accepted a secret subsidy from France, and no act of his reign was more unpopular than the sale next year of Dunkirk. In 1665 a naval Dutch war, due to commercial jealousy, was forced on by Clarendon's enemies, who saw in it a chance of ousting him. In spite of two English victories, with an indecisive engagement between (Lowestoft, Downs, and North Foreland), in June 1667 De Ruyter sailed up the Thames, and burned several war-ships lying at Chatham—that night Charles was very merry in his harem. The peace of Breda (21st July), which in August was followed by Clarendon's downfall, left both nations exhausted, and France the sole gainer. Temple's Triple Alliance (23d January 1668), between England, Holland, and Sweden, was on Charles's part a mere bid for popularity, a means too of raising his price with Louis XIV.; and by the secret Treaty of Dover (20th May 1670) he entered on an offensive alliance with France, became its pensioner, and undertook to effect the conversion of England. A sea-fight with the Dutch in Southwold Bay (1672) was bloody but indecisive; and the strong anti-French feeling forced Charles to conclude a peace (1674), and to consent to the marriage of his niece Mary with his nephew William of Orange (1677). Still, by two other secret treaties (1676-78), and by also intriguing with the opposition, Louis secured

his end, to cut England off from continental politics.

At home, the abortive Savoy Conference was followed by the ejection of nearly 2000 Nonconformist ministers (24th August 1662); the Great Plague (May to December 1665) carried off nearly seventy thousand Londoners; and the Great Fire (2d to 6th September 1666) consumed 13,200 houses, St Paul's, and 86 churches. Sir John Coventry, for plain speaking, got his nose slit by Charles's bullies (1670); the 'stop of the Exchequer' (1672) plunged the chief city bankers in bankruptcy; and Charles's two Declarations of Indulgence (1662-72) were met by the Conventicle and Test Acts, the Dissenters themselves declining to share toleration with the Catholics, for whom such toleration was designed. Clarendon's foes had cause to dread Clarendon's son-in-law, the king's brother, James, Duke of York; and his open profession of Catholicism (1672) gave a pretext for Shaftesbury's Exclusion Bill, and colour to Oates's trumped-up 'Popish Plot' (August 1678 to December 1680), which Shaftesbury fostered, and which cost the lives of fifteen Catholic victims. Himself, if anything, at heart a Catholic, Charles sacrificed them basely to his fears; still, honour, brotherly affection, or French gold, would not let him acknowledge Monmouth for his heir. But the tide had already turned. Men's shame at that shameful panic, and disgust at the thought of a bastard on the throne, caused a Tory reaction; and the Tory reaction drove the Whigs on to open resistance—the Rye-house Plot (1683). Shaftesbury died beyond seas, Lord Essex by his own hand in the Tower, and Russell and Sidney by the headsman's axe.

What English king so absolute as Charles, that Sunday evening, when Evelyn saw him 'toying with his concubines in the glorious gallery' of Whitehall? But on the morrow he was struck with apoplexy, and for three days lay in a stupor. When he came to himself on the Thursday, he would not receive the communion from Bishop Ken; but, thanks to the Duchess of Portsmouth, a priest who had aided him in his escape from Worcester was brought to his bed-side, and by him he was reconciled to the Catholic Church. Then he blessed his children; blessed, too, the Protestant bishops; and at last passed away on Friday the 6th of February 1685. On the night of the 14th he was buried in Westminster Abbey.

So ended the worst reign in English history, whose sole great measure was the Habeas Corpus Act (1679), and whose tortuous politics are generally referable to one or other of the following motives: Charles's fear of again being sent on his travels, the nation's fear of a second great civil war, its hatred of Popery and hatred of the French, the littleness of men's aims and greatness of their greed, and 'backstairs' influence, omnipresent, omnipotent. Such as the reign was, such was Charles himself. With a taste for the arts and for science, he was able, shrewd, affable, easy-going, active of habit, physically brave. His talents serve but to enhance his vices of utter selfishness and abject sensualism. And yet with his subjects he was always popular; the nicknames 'Old Rowley' and 'The Merry Monarch' attest even now the liking that they bore him.

On 22d May 1662 Charles had married poor plain Catharine of Braganza (1638-1705). The marriage was childless, and her influence on English politics was slight as compared with that of his numberless mistresses. Of these, before the Restoration, two only call for notice—'brown, beautiful, bold, but insipid' Lucy Walters (1630-83), the mother of James, Duke of Monmouth and Buccleuch (1649-85); and Catherine Peg, the

mother of Charles Fitzcharles, Earl of Plymouth (1657-80). Then came the splendid termagant, Barbara Villiers or Palmer (1640-1709), whom Charles made Countess of Castlemaine in 1661, Duchess of Cleveland in 1670, and who was mother of the three Fitzroy Dukes of Southampton and Cleveland (1662-1730), Grafton (1663-90), and Northumberland (1665-1716). By 'pretty, witty' Nell Gwynn (1650-87) Charles was father of Charles Beaulieu, Duke of St Albans (1670-1726); almost his last words were 'Let not poor Nelly starve.' There were, besides, 'la belle Stewart' (Duchess of Richmond), the Duchess of Mazarin, and many more, with, last but not least, the hated 'Madam Carwell,' i.e. Louise de Keroualle (1649-1734), the subtle, 'baby-faced' Breton. She was made Duchess of Portsmouth in 1672, French Duchesse d'Aubigny in 1684; and she was the mother of Charles Lennox, Duke of Richmond (1672-1723).

Charles VII., king of France (1422-61), the third son and successor of Charles VI., was born 22d February 1403. On his father's death he was at the head of an army, with which he held possession of the southern provinces of the kingdom; Paris and the north being in the hands of the English, who proclaimed Henry VI. of England king of France, and appointed the Duke of Bedford regent. For some time the events of war were unfavourable to Charles, who was compelled to evacuate in succession Champagne and Maine. In 1426 the Count Dunois gained the first victory over the English at Montargis; but in the year following the latter laid siege to Orleans, a place of great importance to the French, as securing a connection with the north. At this time also, Joan of Arc, the famous Maid of Orleans, by her wonderful courage and confidence of a heavenly mission, roused the fervour both of nobles and people. The siege of Orleans was raised in May 1429; the English retired disheartened, and gradually lost all they had gained in France, while their cause finally became hopeless after the treaty concluded at Arras (1435), between the French king and the Duke of Burgundy. Bayonne, the last stronghold in the south, fell in 1451, and with the death of Talbot under the walls of Castillon in 1453, the whole south finally passed to France, and the Hundred Years' War came to an end. Nothing now remained to the English across the channel but Calais, with Havre and Guines Castle. In 1436 Charles entered Paris. He next devoted himself to the reorganisation of the government, in which everything had fallen into confusion, and under his rule France recovered in some measure from the effects of the terrible calamities which it had endured. His last years were embittered by the conduct of his son, the Dauphin, afterwards Louis XI. He died at Melun on 22d July 1461. See the great work by De Beaucourt (vols. i.-iii. 1881-85).

Charles IX., king of France (1560-74), the second son of Henry II. and of Catharine de' Medici, was born at St Germain-en-Laye in 1550, and succeeded his brother, Francis II., in 1560. He was a proficient in many exercises, possessed much physical energy, and considerable literary accomplishments. But weak and wavering, with all his

cruelty and cunning, he was completely subject to the will of his mother, whose counsels drove him to authorise an act so diabolical that all Europe still shudders at the recollection. The atrocious massacre of St Bartholomew's Day, 24th August 1572, was the culmination of a series of disgraceful treacheries towards the Huguenots. Its consequences politically were the very reverse of favourable to the Catholic cause, while scarce two years later (May 30, 1574) the wretched king died miserably, with all the horrors of hell before his eyes. See BARTHOLOMEW (MASSACRE OF ST).

Charles X., king of France (1824-30), third son of the Dauphin Louis, and grandson of Louis XV., was born at Versailles, 9th October 1757. He received the title of Comte d'Artois, and in 1773 married Maria Theresa of Savoy. The taking of the Bastille on July 14, 1789, prevented the success of a *coup d'état* planned by Artois and the court party. The first emigration headed by Artois and Condé then followed, and a more disastrous policy was never conceived. The attempts of the *émigrés* to restore the old state of things in France by means of foreign intervention did more than any single event to insure the fall of the monarchy. After taking a small part in the war of 1792, Charles went to St Petersburg; thence in May 1793 to England. In spite of the failure of the expedition to Quiberon Bay in June 1795, another was attempted under Artois' leadership in October, but he had not courage to land and place himself at the head of the insurgents, whom he basely left to the vengeance of Hoche and the republicans. After this he lived in obscurity, partly at Holyrood and partly at Hartwell, until the allies entered Paris in 1814, when he appeared in France as lieutenant-general of the kingdom, and issued a proclamation announcing the end of despotism, of conscriptions, and of oppressive taxes. After the second restoration, in alliance with the priests, he headed the party of the Ultras in their struggle with the Constitutionalists. The accession of Villèle to office and the unconstitutional character of the latter part of Louis XVIII.'s reign attested the success of Artois' reactionary policy. The death of Louis, on 16th September 1824, brought him to the throne as Charles X. He took the oath of adherence to the Charte, and was at first popular with all parties; but he soon displayed his intention of restoring as much as possible the absolutism of the old French monarchy. Popular discontent rapidly increased. The victory of the opposition at the elections of 1827 was followed by the resignation of Villèle. A ministry of compromise, headed by Martignac, a moderate politician, succeeded in January 1828, but in August 1829 Charles called to the head of affairs the Prince Polignac, an extreme royalist. A royal speech, of a threatening character, on 2d March 1830, was followed by an address of remonstrance, signed by 221 deputies, upon which the king dissolved the chambers. The deputies who signed the address were all re-elected, but the court taking fresh courage from the success of the expedition to Algiers, the celebrated five ordinances of 25th July were signed by the king, putting an end to the freedom of the press, already largely curtailed, appointing a new mode of election, and dissolving the recently elected chamber. Paris took up arms, the guards were repulsed, the revolution was accomplished in three days, and the king found himself compelled to retire to Rambouillet. As a last resource, he abdicated the throne on 2d August 1830 in favour of his grandson, the little Comte de Chambord. But it was too late; the revolution was completed, and Louis-Philippe, Duke of Orleans, was chosen king of the French. Charles then travelled through France to Cherbourg, and embarked for England in an American ship. He

resided for some time at Holyrood again, and afterwards at Prague, taking no part in the political intrigues and attempts of the Duchess de Berri. He died of cholera at Görz on 6th November 1836.

• **Charles V.**, emperor of Germany, by the extent of his dominions and by virtue of his own genius the greatest European potentate of the 16th century, was born at Ghent in 1500. From his father Philip, the son of the Emperor Maximilian and Mary of Burgundy, he inherited the dominion of the Low Countries, the county of Burgundy, and a strong claim to the imperial crown; from his mother, Joanna, the daughter of Ferdinand and Isabella, he also inherited the kingdoms of Spain and Naples, and the Spanish acquisitions in America. Charles's education was intrusted to Adrian of Utrecht, afterwards pope under the title of Adrian VI., and William de Croy, an experienced politician, who early initiated his pupil into the arts of government, and gained an ascendancy over him which determined Charles's policy during the early years of his rule. To Adrian Charles owed little, and to the end his scholastic acquirements were but meagre. His grandfather, Ferdinand, died in 1516, and the next year Charles left the Netherlands for Spain, where he was acknowledged joint ruler with his mother Joanna, who was incurably insane. On the death of his grandfather, Maximilian, in 1519, he was elected to the imperial crown from a number of competitors, little, however, to the satisfaction of his Spanish subjects, who saw in this honour a blow at their own interests and importance. The following year Charles was crowned emperor at Aix-la-Chapelle, and a few months later (1521) presided at the famous Diet of Worms. The main question he had here to settle, the question of the respective claims of the Catholics and the followers of Luther, was to the end of his reign the great problem which Charles had to settle in Germany. At this his first diet, he displayed the policy which, whenever it was in his power, he ever afterwards pursued—the restoration of Germany to the papal see. The finding of this diet was an edict against Luther and his opinions, and by this edict Charles, at the outset of his reign, leagued himself with Rome against the national sentiment of Germany.

The history of Western Europe during the next quarter of the century is in large degree the history of the rivalry of Charles and Francis I. of France. According to their respective interests, Henry VIII. of England and the successive popes now favoured the one, and now the other; and the result of the conflicting interests of all these potentates was almost continuous war during the whole of that period. The Treaty of Madrid (1526), the Ladies' Peace of Cambrai (1529), and the Peace of Crespy (1544) may be regarded as marking the successive steps in the struggle. The points in dispute between Charles and Francis were these: Charles laid claim to the duchy of Burgundy, as having been unjustly appropriated by Louis XI., and also to the duchy of Milan as a fief of the empire. Francis, on his part, maintained his right to these territories, demanded homage of Charles for Flanders and Artois, and made it a ground of offence that Spain had dispossessed Jean d'Albret of his kingdom of Navarre. It was in Italy that the war between the two monarchs was carried on most vigorously; and during the first period the result was altogether in Charles's favour. Mainly at the instance of Wolsey, Henry VIII. actively aided the emperor, who was still further strengthened by Francis' quarrel with his greatest subject, the Constable Bourbon, who formed a league with Charles and Henry VIII. for the complete subjugation

of France. In 1524 the troops of Charles drove the French out of Italy, invaded Provence, and unsuccessfully besieged Marseilles. Next year Francis, in the endeavour to recover the duchy of Milan, was defeated and taken prisoner at Pavin, and afterwards conveyed to Madrid. In 1526 he was released after signing a treaty in which he yielded to Charles on all the points at dispute between them. In this year Charles married Isabella, sister of John III. of Portugal, to whom he was much devoted. Meanwhile, there was a growing alarm at the successes of Charles, and the Holy League was formed against him by Pope Clement VII., Henry VIII., Francis, and the Venetians. In 1527 a motley army of Spaniards, Italians, and Germans, led by Bourbon, who fell in the assault, sacked Rome, and imprisoned the pope, to the horror of all Christendom. Charles was denounced as the author of the sacrilege, and cartels of defiance were sent to him by Henry and Francis. He disclaimed all part in the affair; yet it was altogether in his interest that it should have happened, as the pope was then the most active of his enemies. The failure of Francis to seize the kingdom of Naples led to the Peace of Cambrai (1529), by which Charles was left master of Italy, and was relieved from his homage for Flanders and Artois.

During all these years Charles had been resident in Spain, where, on his arrival from Germany, he had found things in an extremely unsettled state owing to certain encroachments lately made on the privileges of the great cities. A general insurrection had taken place during his absence, which only after a protracted struggle had been quelled by the help of the nobles. Charles, by his tact and policy, succeeded in completely putting down the sedition; and, while largely increasing the power of the crown, contrived to render himself highly popular throughout the country. All through his reign, however, he had great difficulty in extorting from the Spanish Cortes the funds necessary to carry on his foreign schemes. In 1529 Charles proceeded to Italy; and at Bologna was crowned by the pope king of Lombardy and emperor of the Romans. As he was on his way to Germany, where the religious difficulty was still the burning question, he urged the pope, though unavailingly, to call a general council which should settle once for all the points at issue. At the Diet of Augsburg (1530) Charles confirmed the Edict of Worms, and the Protestants (now first so called), in self-defence, formed the League of Schmalkald. The threat of an invasion by the Turkish sultan, however, forced Charles to make important concessions, and with the support of the appeased Protestants he was enabled to take the field against the Turks. No battle ensued, but the sultan was forced to retire; and Charles was again at liberty to return to Spain by way of Italy, where once more he earnestly urged on the pope the necessity of a general council. In 1535 Charles achieved in person the most brilliant of all his exploits—the destruction of the power of the great corsair Barbarossa, and the capture of Tunis. Meanwhile, Francis was still in active hostility against him; and in 1536 Charles himself once more proceeded to Italy and invaded Provence with a large army. By making the country a desert, Francis forced his enemy to retire without effecting any actual conquest. As another expedition into Picardy had also miscarried at the same time, this was the most disastrous year that Charles had yet experienced. War, however, still proceeded; and Francis, in desperation, and to the disgust of Christian Europe, called in the aid of the Turk. In 1538, both parties being now exhausted, the pope (Paul III.), Francis, and Charles

met at Nice, and agreed to a ten years' truce on the condition that they should retain the possessions then in their hands.

The year 1539 was for Spain one of the most important during Charles's rule. To meet his extraordinary expenditure, Charles held in that year a meeting of Cortes with the view of gaining its consent to the imposition of new taxes. As at this meeting the nobles were especially refractory, they were therefore excluded from the Cortes; and from this time dates the decline of their power in the state. In the same year, by the romantic courtesy of Francis, Charles travelled through France to the Low Countries, where the insurrection of Ghent, on account of a certain illegal tax, called for his presence. After having quelled this insurrection with the utmost severity, and stripped the town of all its ancient privileges, Charles proceeded to Germany, where another diet held to settle the religious differences was as unsuccessful as its predecessors. During this journey also Charles engaged in the most disastrous of all his enterprises. In the autumn of 1541, against the advice of his most experienced seamen, he conducted from Italy a fleet against Algiers, whose piracies had been the terror of the south of Europe. A succession of storms completely destroyed the fleet, and Charles himself with difficulty reached the coast of Spain. A new quarrel having arisen between Charles and Francis regarding the duchy of Milan, the ten years' truce fell through, and war again went on for the next three years. The most notable event of the war was the wintering of the Turkish fleet at Toulon, by arrangement with the French king, at which Henry VIII. was so indignant that he concerted with Charles an invasion of France, when the emperor actually came within two days' march of Paris. By this double invasion Francis was again forced to make an unfavourable peace—that of Crespy (1544), by which he once more renounced all claims to Italian territory, and agreed in conjunction with Charles to make war on the Turks.

Having thus triumphed over Francis, whose death in 1547 left his hands freer than they had ever been since the beginning of his reign, Charles now sought to carry out the policy he had always had at heart with regard to Germany. In this policy he had two objects—the suppression of Protestantism and the succession of his son Philip to the imperial crown. The news that Charles had made a league with the pope for the extinction of heresy drove the Protestants to arms, but two campaigns saw their power broken, and two of their most important leaders, the Landgrave of Hesse and the Elector of Saxony, taken prisoners. The Augsburg Interim (1548) followed as a temporary arrangement till a general religious council should settle all difficulties. This arrangement did not satisfy the Catholics, but it was especially objectionable to the Protestants, upon whom it was forced with great violence. Charles's severe enforcement of the Interim, his cruel treatment of the Landgrave of Hesse and the Elector of Saxony, and his evident design to make himself absolute master of Germany, led to the overthrow of all his plans. Maurice of Saxony, a young man of extraordinary talents and great ambition, who, although a Protestant, had hitherto seemed to support Charles in all his schemes, saw that the emperor's power rested in reality on a most insecure foundation. By a subtle line of policy Maurice contrived to gather round him a large army, while Charles, still trusting in his fidelity, had dismissed the troops by whose aid he had lately had Germany at his feet. The emperor all but fell into the hands of Maurice, who was now in a position to command the most favourable con-

ditions for the Protestants. Accordingly, by the Treaty of Passau (1552), and, after the death of Maurice, by the Peace of Augsburg (1555), Protestantism received legal recognition, and Charles saw his life's schemes finally baffled. In his other object he was equally unsuccessful. He had tried in vain to persuade his brother Ferdinand to waive his claims to the empire in favour of Philip, and the princes of Germany, Catholic as well as Protestant, refused to entertain Charles's suggestion. Thus disappointed in his dearest hopes, and broken in health by repeated attacks of the gout, to which he had been subject since his 29th year, Charles publicly resigned in favour of his son (1555), whom he had married the previous year to Mary of England. Retiring to the monastery of Yuste, in a beautiful valley of Estremadura, he spent the rest of his life in complete seclusion. Much of his time was given up to religious exercises, but he never ceased, almost till his death on 21st September 1558, to take the keenest interest in affairs of state, and his advice, still given in emergencies, was received by his son with the greatest respect.

Charles V. and Luther, the two most prominent figures of the 16th century, are also the best representatives of its great conflicting principles. The religious revolution, and the spirit of nationality which that revolution evoked wherever it was realised, are the ideas associated with the name of Luther. The aim of Charles was a great empire in Western Europe, of which the pope should be the spiritual, the House of Austria the temporal, head. In opposing this aim, and thus preserving the balance of power as well as the individuality of the Western nations, Francis, according to Ranke, was justified in calling in the Turks. Charles had a mind and heart equal to great undertakings; yet he not only failed to achieve his purpose during his life, but bequeathed to his son a policy attended by the most disastrous results. It was in carrying out this policy that Philip lost the Netherlands to Spain, and that he arrested Spain itself in its national development. The position also in which Charles left the religious question by the Peace of Augsburg inevitably led to the Thirty Years' War, with all its frightful consequences to Germany. Charles's personal qualities were such as to win him the affection of his immediate dependents, and to render him popular with all classes of his subjects among all the peoples under his sway. He was sincerely devoted to the church, and religious motives greatly influenced him in all his counsels. His private morals bear a favourable comparison with those of contemporary princes. In person he was slight and graceful, and his manners were marked by singular refinement and dignity; but throughout all his life he was haunted by the dread of his mother's mental affliction. Don John (q.v.) of Austria was an illegitimate son of Charles V.

See Robertson's *Life of Charles V.*, and Prescott's continuation; Ranke's *History of the Reformation in Germany*; Sir W. Stirling-Maxwell's *Cloister Life of Charles V.*; and Mignet's *Charles-Quint*.

Charles X., or CHARLES-GUSTAVUS, king of Sweden (1654-60), the son of John Casimir, Count Palatine, and Catherine, sister of Gustavus-Adolphus, was born at Nyköping, 8th November 1622. After his studies at Upsala, he took part in the Thirty Years' War under Torstensohn. On the abdication of his eccentric cousin, Queen Christina, whom he had wooed in vain, Charles succeeded as next heir to the throne of a kingdom which the folly and extravagance of the queen had reduced to an almost bankrupt condition. Charles was the second of the three great warrior-monarchs of Sweden, but unlike his uncle, who could plead religious grounds, and his grandson, who was at

first forced to fight for self-preservation, Charles seemed to make war principally for war's sake. He was now free to gratify his passion for war. First he attacked Poland in July 1655, because the Polish king had not resigned his claim to the Swedish throne, and in a few weeks overran the whole country. Next he forced the Great Elector of Brandenburg to acknowledge his lordship over the duchy of Prussia, then crushed the forces of the Polish king anew in a terrible three-days' battle at Warsaw (July 28-30, 1656). He next assailed the Danes, who had declared war against him, crossed the Great and Little Belt on the ice, and speedily made himself master of all the continental possessions of Denmark. Marching from isle to isle over the frozen sea, he extorted the Treaty of Roeskild (7th March 1658), which gave to Sweden Halland, Scania, Blekingen, Bornholm, and the other Danish possessions beyond the Sound, and emancipated Sweden from the Sound Dues. His offers to the Dutch and English to share in the partition of Denmark being declined, he invaded Zealand alone in 1659, and attacked Copenhagen, but was beaten off by the Danes, aided by the Prussians and Dutch. Soon after he died suddenly at Gothenburg, February 23, 1660. He was succeeded by his son, Charles XI. (1660-97), then only four years old. See SWEDEN.

Charles XII., king of Sweden (1697-1718), was the son of Charles XI., and was born at Stockholm, 27th June 1682. On the death of his father in 1697 he ascended the throne, and notwithstanding his youth the States declared him of age to assume the reins of government. The neighbouring powers thought this a favourable time to humble Sweden, then the great power of the north; and Frederick IV. of Denmark, Augustus II. of Poland, and the Czar Peter the Great concluded a league for this object. The Danes began by invading the territory of the Duke of Holstein Gottorp, husband of the eldest sister of Charles. The young king at once flung an army into Zealand, and in concert with Sir George Rooke's Anglo-Dutch squadron so threatened Copenhagen both by land and sea that the king was fain to sue for peace. Charles now hastened to meet the Russians, who lay under the walls of Narva, 50,000 strong, stormed their camp with but 8000 Swedes, and routed them with great slaughter, 30th November 1700. He next dethroned Augustus II., and procured the election of Stanislaus Leszczyński as king of Poland. Augustus supposed himself safe at least in Saxony, his hereditary dominion, but was followed thither, and humbling terms of peace were dictated at Altranstädt in 1706. Patkul, born a Livonian, but now the Czar's ambassador at Dresden, Charles caused to be broken on the wheel for treason, after a form of trial. In the autumn of 1708 he had collected an army of 43,000 men in Saxony, and in the January of the following year suddenly burst into Russia, and almost captured the Czar at Grodno. He next drove the Russians before him, and had already forced the Beresina and won a battle at Smolensk, which opened up to him the road to Moscow, when he suddenly turned southwards to the Ukraine, trusting to the promises of the Cossack *hetman* Mazeppa. But Mazeppa failed to bring forward his 30,000 Cossacks, and the king's reinforcements from Sweden were cut off by the watchful Czar, so that the Swedes had no alternative but to endure the hard winter of 1708-9 in the midst of an impoverished and hostile country. In spring Charles, with a force reduced to 23,000 men, laid siege to Pultowa, but the Czar hastened to oppose him, and defeated him after a desperate struggle, on the 8th July. Charles fled with a handful

of attendants across the Turkish frontier to Bender.

Augustus now revoked the treaty of Altranstädt, and the Czar and the king of Denmark in concert assailed the Swedish territories. But the regency in Stockholm adopted measures of effective resistance, and Charles prevailed upon the Porte to commence a war against Russia, in which Peter seemed at first likely to suffer a severe defeat. But Russian agents succeeded in inspiring the Turks with suspicions concerning the ultimate designs of their impracticable guest, and accordingly Charles was seized, resisting desperately sword in hand, and conveyed to Demotica. At last he contrived to escape, and made his way through Hungary and Germany in sixteen days, till he reached Stralsund on the 21st of November 1714. A month later the town was forced to capitulate to an allied army of Danes, Saxons, Prussians, and Russians, on which the king crossed to Lund. His passion for war led him to attack Norway early in 1716; and soon after, under the advice of the Baron von Görtz, he formed a scheme which commended itself to his love of fighting and his vast ambition. He was to make terms with the Czar by surrendering the Baltic provinces of Sweden, then conquer Norway, next land in Scotland and replace the House of Stuart on the English throne, with the help of the Jacobite party within and that of Cardinal Alberoni without. No sooner had he purchased his peace with the Czar than he burst into Norway. Early in 1718 he commenced the siege of Fredrikshall, and while hastening on the works in the dead of winter with all his characteristic impetuosity of impatience, was killed by a musket-shot from the fortress. Some writers have maintained that his death was due to treachery, and a somewhat unscientific examination of his skull in 1746 seemed to give some colour to the belief; but a new examination by command of Charles XV. in 1859 proved conclusively that the fatal shot must have been fired from a height downwards, and that therefore the king's death was due to his own reckless exposure of his person to the fire of the enemy.

The character of Charles was full of strange contradictions. He was brave to the pitch of reckless folly, determined to the point of foolish obstinacy. Pleasure had no attractions for him: he shared the coarsest food and severest labour of the common soldier with an easy cheerfulness that won him the passionate devotion of his men. All external marks of rank he despised: his dress was simple, and Swedish in form and colour—a loose blue coat, with turned-down collar, and large plain brass buttons; buff-coloured waistcoat; a black kerchief, doubly folded round his neck; coarse felt hat, and high broad-toed riding boots with massive steel spurs. His hardy frame defied alike fatigue and the extremes of heat and cold. He was able and sagacious in counsel, and had a mind capable of the vastest designs. But his ambition was fatal to his country, and after his death, Sweden, exhausted by his wars, ceased to be numbered among the great powers. The strange vicissitudes of his career are reviewed in thirty of the finest lines of Johnson's noble poem, *The Vanity of Human Wishes*—the concluding passage is as well known as anything in English literature:

His fall was destin'd to a barren strand,
A petty fortress, and a dubious hand.
He left the name at which the world grew pale,
To point a moral, or adorn a tale.

Voltaire's well-written *Histoire de Charles XII.* will continue to be the chief life, spite of its errors. An eloquent sketch of his career, read by King Oscar II., then Duke of Östergötland, at the

inauguration of a statue to Charles XII. in Stockholm on the 150th anniversary of his death, and afterwards published, was translated into English by G. P. Apgeorge (1879).

Charles XIV., king of Sweden and Norway (1818-44), originally JEAN BAPTISTE JULES BERNADOTTE, was born at Pau, in the south of France, January 26, 1764, and was the son of a lawyer. He entered the French army in 1780 as a common soldier; became an ardent partisan of the Revolution, and fought his way up to the command of a division in 1794, and a marshal's baton in 1804. He distinguished himself greatly in the German campaigns in 1796, and the year after under the eye of his great chief himself in Italy. In 1799 he was minister of war, and for his conduct at Austerlitz was named in 1805 Prince of Pontecorvo. In the campaigns of 1806 he commanded the first army corps. After Jena he pursued the Prussians to Halle, cut off the reserve under the Prince of Würtemberg, next pursued the redoubtable Blücher to Lübeck, and compelled him to surrender (November 7). He received the command of the French troops in North Germany and Denmark, and led the Saxon troops at Wagram in the war against Austria. But he had never been liked or trusted by Napoleon, whose jealousy and dislike now became so apparent that Bernadotte left the army in disgust, and returned to Paris. He was afterwards sent by the ministerial council to oppose the British, who had landed at Walcheren, but meantime the breach between the emperor and him grew wider. In 1810 he was elected crown prince and heir to the throne of Sweden. Almost the only condition imposed on him was that of joining the Protestant Church. He changed his name to Charles John; and the health of the Swedish king, Charles XIII., failing in the following year, the reins of government came almost entirely into his hands. He refused to comply with the demands of Napoleon, which were opposed to the interests of Sweden, particularly as to trade with Britain, and was soon involved in war with him. He took part in the great and final struggle of the allies with Napoleon at Leipzig, but showed much reluctance to join in the invasion of France, and was tardy in his progress southward. There seems good reason to believe that the French throne was within his own ambition, and that his disinclination to act against his native country was due as much to policy as to patriotism. He became king of Sweden on the death of Charles XIII. in 1818, and won for himself the character of a wise and good king. Education, agriculture, manufactures, commerce, and great public works, as well as the military strength of the kingdom, were promoted by his care. He died March 8, 1844, and was succeeded by his son Oscar.

Charles d'Orléans, son of Louis d'Orléans, a duke who was murdered by the Burgundians, and of Valentina of Milan, was born in May 1391. He was the grandson of Charles V. of France, and the father of Louis XII. He was taken prisoner at Agincourt, and kept in captivity in England from 1415 to 1440, when he was ransomed. He wrote a number of lyrics while in prison and after his return to France. At Blois, where he held his court, he gathered together the chief French writers of his time, and took part with them in poetical tournaments, in one of which François Villon competed successfully. He died in 1465. He has been termed the father of French lyric poetry, but he has no claim to the title. His light and graceful lyrics are the last flowering of the courtly poetry of the middle ages; they show no trace of the modern spirit which appears so strongly in the works of his con-

temporary Villon (q.v.). His favourite themes are love and the spring-time; his favourite form is the *rondel*, with two rhymes, of which he is considered the chief master, as Villon is of the *ballade*, and Voiture of the *rondeau*. An edition of his works (ed. J. M. Guichard) appeared in 1842, and another (ed. Héricault) in 1874.

Charles the Bold, Duke of Burgundy (1467-77), son of Philip the Good of Burgundy and of Isabella of Portugal, was born at Dijon on 10th November 1433, and bore, during his father's life, the title of Count of Charolais. From his youth he was a declared enemy of Louis XI. of France, the nominal feudal superior of Burgundy, and he early formed an alliance with the Duke of Brittany and some of the great nobles of France for the maintenance of feudal rights against the crown. Their united forces ravaged Picardy and Isle-de-France, threatened Paris, defeated the king at Montherly, and extorted from him favourable terms. In 1467 Charles succeeded his father as Duke of Burgundy. Richer and more powerful than any prince of his time, he conceived the design of restoring the old kingdom of Burgundy, and for this purpose of conquering Lorraine, Provence, Dauphiné, and Switzerland. Whilst he was making preparations for war, Louis invited him to a conference, and while his rival hesitated, by his agents stirred up the citizens of Liège to revolt. Charles next consented to the conference, and the news coming of what had taken place at Liège, he seized the king, and had not he been withheld by his councillor Comines, would have put him to death. He compelled Louis, however, to accompany him to Liège, and sanction by his presence the cruelties which he inflicted on the citizens. War raged between them afterwards with little intermission till 1475. In September of that year Charles turned anew to his favourite scheme of conquest, and soon made himself master of Lorraine. Next year he invaded Switzerland, stormed Granson, and hanged and drowned the garrison; but was soon after terribly defeated by the Swiss near that place, and lost his baggage and much treasure. Three months later he appeared again in Switzerland with a new army, and laid siege to Morat, where he sustained another and more terrible defeat (June 22, 1476). The news that the young Duke René of Lorraine was attempting to recover his territories roused him from despair. He laid siege to Nancy; but his army was small, and his Italian mercenaries went over to the enemy. Charles fought in vain with all his wonted recklessness and courage, and perished in the battle, January 5, 1477. His daughter and heiress, Mary, married the Emperor Maximilian I. Charles's great size and strength, his immense ambition, and reckless audacity, combined to make him the most striking figure of his time. With his life ended the long successful resistance of the great French vassals to the central power of the monarchy. See Comines, *Mémoires*; De Barante's *Histoire des Ducs de Bourgogne*; and special books by Kirk (3 vols. Lond. 1863) and Hoch (Basel, 1876).

Charles Edward. See STEWART.

Charles (KARL LUDWIG JOHANN), Archduke of Austria and Duke of Teschen, third son of the Emperor Leopold II., was born at Florence, 5th September 1771. Already, spite of his youth, a distinguished soldier, he was intrusted in 1796 with the chief command of the Austrian army on the Rhine. He fought with great success against Moreau at Rastadt, defeated Jourdan in several battles, drove the French over the Rhine, and concluded his victories by taking Kehl in the winter. In 1799 he was again at the head of the army on the Rhine, was several times victorious over

Jourdan, and even successfully opposed Massena. Next year bad health compelled him to retire from active service; but he accepted the governor-generalship of Bohemia, where he soon formed a new army. After the battle of Hohenlinden he was again called to the chief command, and succeeded in staying the rapid progress of Moreau until the armistice which preceded the peace of Lunéville. In 1805 he commanded the army opposed to Massena in Italy, and fought the hard battle of Caldiero; but upon bad tidings from Germany, made a masterly retreat from the left bank of the Adige to Croatia. In 1809 he won the great battle of Aspern, which first showed to Europe that Napoleon was not invincible; but Napoleon soon retrieved his fortunes at Wagram, and the archduke was now compelled to give way before the enemy, till he reached Znaim, where an armistice was concluded on 12th July. In the campaigns of 1813 and 1814 he had no part; and he lived in retirement till his death, 30th April 1847.

Charles Albert, king of Sardinia (1831-49), born 29th October 1798, was the son of the Prince Charles Emmanuel of Savoy-Carignan, and in 1800 succeeded to his father's title and estates in France and Piedmont. In 1817 he married Maria Theresa, daughter of the Archduke Ferdinand of Tuscany. When the revolutionary movement took place in Piedmont in 1821, he was made regent, upon the abdication of Victor Emmanuel, until Charles Felix, the brother of the late king, should arrive to assume the sovereignty. In 1829 he was appointed viceroy of Sardinia, and on the death of Charles Felix in 1831 he ascended the throne. His prudent moderation brought upon him the impatient denunciations of Mazzini, but earned him the applause of all moderate and far-sighted men throughout the peninsula, who began to see that the salvation of Italy could be worked out through the house of Savoy alone. The king's zeal for the cause of a united Italy was no mere selfish eagerness for the aggrandisement of his house, but a feeling as enlightened and patriotic as the sagacious calculation of Cavour, the fiery and reckless valour of Garibaldi, or the prophetic ardour of Mazzini. In the March of 1848 he declared war against Austria; but gradually lost ground in the struggle, until, after the fatal battle of Novara, 24th March 1849, to save his kingdom he had to resign the crown in favour of his son, Victor Emmanuel. He next retired to Portugal, where he died, broken-hearted and misunderstood, at Oporto on 28th July of the same year. See *Life by Cibrario* (Turin, 1861).

Charles's Wain (i.e. 'charl's wagon'), the constellation of Ursa Major (q.v.).

Charleston, a port of entry, capital of a county of its own name, and the largest city of South Carolina, is situated on a tongue of land between the rivers Ashley and Cooper, which unite immediately below the town and form a beautiful and spacious harbour, communicating with the ocean at Sullivan's Island, a popular sea-bathing resort, 7 miles below. It is 118 miles NE. of Savannah, 580 miles SW. of Baltimore, and 540 miles SSW. of Washington. The ground on which the city is built is elevated 8 or 9 feet above the level of the harbour at high tide, which rises about 6 feet, flowing by the city with a strong current, thus contributing to its salubrity. It has a water front of 9 miles. A shifting sandbar extends across the mouth of the harbour, affording, however, two entrances, of which the deepest, near Sullivan's Island, has 16 feet of water at low tide. Jetties, which are expected to give a depth of 25 feet of water on the bar, have since 1878 been under con-

struction by the national government. The harbour is defended by Castle Pinckney and Fort Sumter, each on an island, the former 2 and the latter 6 miles below the city, and also by Fort Moultrie, on Sullivan's Island. Forts Ripley and Johnson, now abandoned, have only an historic interest. At the entrance of the harbour is a lighthouse, with a flashing light, 125 feet high.

Charleston is regularly built, and extends about 3 miles in length and nearly $\frac{1}{2}$ miles in breadth. It has a copious water-supply from a large artesian well (1970 feet in depth). The streets, many of which are broad and bordered with shade-trees, pass, for the most part, parallel to one another, from the Cooper to the Ashley River, and are intersected by others nearly at right angles. Many of the houses are of brick, some of them of superior elegance; others are of wood, neatly painted, and embowered during the summer season amid a profusion of foliage. Among the public buildings are the custom-house, the city hall, the court-house, the citadel, the academy of music, the theatre, the orphan asylum, and the police barracks. The custom-house is a handsome edifice, built of granite and white marble. At the southern extremity of the city is a small park called the Battery or White Point Garden, with a fine promenade on the sea-wall. The most important educational and literary institutions are the Charleston College (non-sectarian), which was founded in 1785 and reorganised in 1837; the Medical College of South Carolina (1833); the State Military Academy, also called the Citadel; the high school; the female seminary; a normal school for girls; and the Charleston Library (1748). The Charleston College has an excellent museum of natural history. There are good public, private, and parochial schools for white and coloured children. Charleston is the seat of an Episcopal and a Roman Catholic bishop, and contains forty churches. St Michael's Church (Episcopal) is a brick structure, with a steeple 180 feet high, and a chime of bells imported from England in 1764. Among the benevolent institutions are the city hospital, the Confederate Home for Widows, the almshouse, the asylum for the aged and infirm, and the orphan asylum, which is liberally endowed, and can accommodate three hundred children. There are also Catholic orphan asylums and a convent.

Charleston is the chief commercial city of South Carolina, and has an advantageous position for trade. Steamships ply regularly between this port and New York, Philadelphia, Baltimore, and Florida; and three railroads meet here, with a large wharf frontage, elevators, and every facility for through shipments and the quick despatch of freight. The coastwise trade far exceeds the foreign in extent and importance. The chief articles of export are cotton, rice, naval stores (rosin, oil of turpentine, tar, &c.), cotton goods, timber, market-garden produce, phosphate rock, and crude and manufactured fertilisers; the value of the principal exports in 1887 was £6,111,672. The imports, chiefly salt, iron, ties, ale, brimstone, kainite, and fruits from the West Indies, were returned at £111,771. There is a large wholesale distributing trade in dry-goods, clothing, drugs, &c.; and the city has large machine-shops, cotton-presses, grist-mills, cotton-mills, rice-mills, a bagging-factory, ship-yards, a good dry-dock for large ships, and extensive manufactures of phosphate of lime, which abounds in the vicinity. Whereas only 6 tons of phosphate were mined in 1867, 285,000 tons were raised in 1887.

The city was founded in 1680; a few years later a company of French Huguenots, exiled for their religion, settled at this place. On the

28th June 1776 a British squadron attacked the garrison on Sullivan's Island, consisting of 400 men under Colonel Moultrie, who defended the place with success. Charleston was afterwards besieged by Sir Henry Clinton from April 1, 1780, to May 12, when it was surrendered by General Lincoln. On the 12th of April 1861, the Confederates initiated the civil war by the bombardment of Fort Sumter, which they took the next day. In 1861 about half the city was destroyed by fire, and a considerable part was not rebuilt until after 1865. In April 1863 a Federal fleet of nine ironclad vessels, commanded by Admiral Dupont, attacked the fortifications of Charleston without success. After a long siege the place was evacuated by the Confederates, February 17, 1865. On 31st August 1886 the city was visited by a severe earthquake; nearly 7000 buildings were either destroyed or seriously injured, and several lives were lost. The earthquake was followed by a very general reconstruction of the business part of the city. Pop. (1800) 18,711; (1820) 24,780; (1840) 29,261; (1860) 40,522; (1870) 48,956, of whom 22,749 were white and 26,207 were coloured; (1880) 49,984; (1887) 62,357 (27,543 white, 34,814 coloured).

Charleston, or KANAWHA, capital of West Virginia and of Kanawha county, is situated on the Great Kanawha River, at the mouth of the Elk, 369 miles WNW. of Richmond by rail. Large quantities of bituminous coal and salt are procured near by. Charleston was made state-capital in 1885, having been so previously from 1870 to 1875. Pop. (1880) 4192; (estimated 1887) 9000.

Charlestown (Massachusetts). See BOSTON and BUNKER HILL.

Charlet, NICOLAS TOUSSAINT, a French painter and engraver, born at Paris in 1792, held a clerkship under the Empire, but lost it at the Restoration (1815), and in consequence betook himself to art. After studying awhile under Gros, he gradually formed for himself a style in which he had no rival. The Béranger of caricature, he was especially successful in his sketches of children and military incident. His drawings numbered about 2000. Charlet died October 29, 1845. See his *Life* by Lacombe (1856).

Charleville, a town in the French department of Ardennes, on the Meuse, opposite Mézières, with which it communicates by a suspension bridge. It has manufactures of hardware, leather, and beer; and the Meuse affords facilities for trade in coal, iron, slate, wine, and nails. Pop. (1872) 12,059; (1886) 16,856.

Charlevoix, PIERRE FRANÇOIS XAVIER DE, a French Jesuit traveller, was born in St Quentin in 1682, twice visited Canada, and voyaged down the Mississippi to New Orleans. He published his journal, histories of San Domingo, Japan, and Paraguay, and a *Histoire de la Nouvelle France* (1744; Eng. trans. New York, 6 vols. 1865-72). He died at La Flèche in 1761.

Charlock. See MUSTARD.

Charlotte, capital of Mecklenburg county, North Carolina, 265 miles ENE. of Atlanta, is the terminus of several railways, has manufactures of carriages, cotton goods, tobacco, &c., and is the seat of a Presbyterian university (1867). Pop. (1880) 7094.

Charlotte, PRINCESS, born at Carlton House, London, 7th January 1796, was the only child of the future George IV. and Caroline of Brunswick, who parted immediately after her birth. A bright, lively, warm-tempered girl, she was brought up in strict seclusion, under various governesses and sub-governesses, seeing her father rarely, and her mother only for two hours a week. Her six

months' engagement to Prince William of Orange she herself broke off in June 1814, greatly to George's fury; had the match come off it might have been as momentous in its consequences as that of the Princess Mary to another Prince William of Orange. On 2d May 1816 she married Prince Leopold of Saxe-Coburg; but the marriage, a happy one, was cut short on 5th November 1817 by her death, after giving birth to a still-born boy. See the *Memoir* by Lady Rose Weigall (1874), and the monograph by Mrs Herbert Jones (1888).

Charlotte Amalie, the capital of the West Indian island of St Thomas (q.v.).

Charlottenburg, a town of Prussia, on the Spree, 3 miles W. of Berlin, with which it is connected by a road leading through the *Thiergarten*. It contains a royal palace, which was founded in 1696 for Sophie Charlotte, the second wife of Frederick I., and which has a fine park, with a large orange-grove, a theatre, and a mausoleum; here are the remains of Frederick William III. and his queen, with their statues by Rauch, and here their son, the Emperor William I., was interred in 1888. In the town are a royal institute of glass-painting, an artillery and engineering school; the manufactures include iron-ware, machinery, porcelain, glass, paper, leather, chemicals, and beer. Pop. (1871) 19,518; (1880) 30,483; (1885) 42,371.

Charlottetown, the capital of Prince Edward Island, on the south coast, stands on the Hillsborough estuary, which forms a secure and commodious harbour for the largest vessels. The town has two colleges, an iron-foundry, a woollen-factory, and shipbuilding yards. Pop. (1881) 11,485; (official estimate, 1888) 13,000.

Charm (through Fr. from Lat. *carmen*, 'a song'), properly a form of words, generally in verse, supposed to possess some occult power of a hurtful, a healing, or a protective kind; hence applied to anything which exercises an irresistible power to please and attract. Charms exert their influence either by being recited, or by being written and worn on the person; and, in this latter case, they may be classed with Amulets (q.v.). The nature of this superstition will be considered under INCANTATION; see also MAGIC.

Charnel-house, a chamber situated in a churchyard or other burying-place, in which the bones of the dead which were thrown up by the grave-diggers were reverently deposited. It was generally vaulted in the roof, and was often a building complete in itself, having a chapel or chantry attached to it. In such cases, the charnel-vault was commonly a crypt under the chapel; and even in churches it was not uncommon for the vault or crypt to be employed as a charnel-house.

Charnwood Forest. See LEICESTERSHIRE.

Charolais is a district in the French department of Saône-et-Loire, noted for its fine cattle.

Charon, in classical mythology, the son of Erebus and Nox, is first mentioned by the later writers of Greece. His duty was to ferry the shades of the buried dead across the rivers of the under-world. For this service he exacted an *obolus* from each, and consequently this coin was placed in the mouth of the dead. If this rite was neglected, Charon refused to convey the unhappy shade across, and it was doomed to wander restlessly along the shores of Acheron. He is generally represented as a gloomy old man, with a rough beard and wretched clothes. In the Etruscan monuments he holds a hammer. In the folklore of modern Greece Charon still survives as a kind of shadowy representative of death and a mysterious under-world. (The Greek is *chárōn*; the English pronunciation, *kārōn*.)

Charpie. See LINT.

Charquil. See JERKED BEEF.

Charr, or **CHAR,** a name applied to a number of fresh-water fishes in the salmon and trout genus *Salmo*. They are found almost exclusively in mountainous lakes—e.g. in Switzerland, Scandinavia, and in the English Lake district. The presence of charr has also been recorded in Scotland (especially in Loch Earn), Ireland, and Wales; but their British headquarters are in Windermere and the adjacent Cumberland and Westmoreland lakes. The charr differs from the true salmon only in a few small points, such as the restriction of the vomer teeth to the head of that bone; and the distinctions between the numerous recorded species of charr seem rather local variations than of specific importance. The title *S. salvelinus* is one of the commonest; *S. alpinus* is also applied to both Swiss and English charrs; *S. umbla* is sometimes restricted as the title of the *ombre chevalier* of the lakes of Constance, Neufchâtel, and Geneva; and many other names indicate slight differences in size, form, colour, &c. The common English and Swiss charr is distinguished by the bright red and orange colour of the abdomen during the breeding season, but at all seasons the variable colours are bright and pleasing. They thrive only in clear water, frequent the deeper parts of the lake, and feed on insects and small crustaceans. At the end of autumn and beginning of winter they leave the lake to find in the inflowing streams the stony bottom necessary for the deposition of the ova. The charr is as palatable as it is beautiful, and is much valued as a dainty, both when fresh and potted. It is to be regretted that the habit of catching them by wholesale netting at the mouths of streams at the beginning of the spawning season has led to a great reduction of their numbers in the English lakes. The American charr (*S. fontinalis*) is bred by the Fish Commission, and has been introduced into Britain.

Charron, PIERRE, a French moralist and theologian, born at Paris in 1541. He studied for the law, but after being called to the Paris bar, entered the church, and became a conspicuous member of the *politiques*, or party of moderate Catholics. He assailed the League in his *Discours Chrétiens* (1589), vindicated Catholicism against Protestantism in his treatise *Les Trois Vérités* (1594), and in his chief work, the treatise *De la Sagesse* (1601), took a sceptical attitude towards all forms of religion. He died in 1603. He was a friend and disciple of Montaigne, to whom he was, as a writer, immeasurably inferior, and from whose essays he borrowed freely. An edition of his principal work was published at Paris in 1789.

Chart, a marine or hydrographical map, exhibiting a portion of a sea or other water, with the islands, coasts of contiguous land, soundings, currents, &c. (see MAP). Chart-making has been traced back to about the beginning of the 13th century; now most civilised countries have their system of charts. In the English service, when coasts have been surveyed by the Admiralty, charts are engraved, and are sold at various prices, from 3s. down to 6d. each. This price is below their cost, the object being to encourage their general use as much as possible. The navigating charts, showing the dangers of coasts with sufficient clearness to enable mariners to avoid them, are generally on the scale of half an inch to a mile; those of larger size show all the intricacies of the coast. The merchant-service is supplied with charts by agents, who receive a stock from the Admiralty, and keep them on sale. The preparation of charts is part of the duty of the Hydrographical Department at the Admiralty. In the financial year

1887-88 a sum of no less than £13,600 was provided for this branch, irrespective of the surveying that preceded the engraving of the charts, which always costs a much larger sum. In the five years ending with 1886 the Admiralty sold 691,782 charts (besides supplying the navy gratis); the amount received was £40,151. Eight of Her Majesty's ships, a Queensland gunboat, and two hired steam-vessels were engaged in examining and charting seas and coasts in 1887. The number of charts printed in 1887 was 228,817.

The United States coast survey, a vast undertaking, was begun in 1807, carried on intermittently till 1845, and since then more systematically, save during the civil war, under Professor Bache and his successor, Professor Pierce. In the American service, the coasts of the United States are surveyed and the charts produced by the coast and geodetic survey attached to the Treasury Department, and the unsurveyed foreign coasts are surveyed by the Bureau of Navigation, the charts being produced by the Hydrographic Office, Navy Department. The coast and geodetic charts are sold at from 10 cents to \$1 each, being the cost of printing and paper. Naval vessels are supplied free. The charts are obtainable at coast and geodetic survey agencies at all seaports of the United States. They exhibit accurate and minute topography as far inland as will supply landmarks for the navigator, or serve for purposes of defence; the shore line at high-water and sanding to mean low-water; soundings, contours, and material of bottom at different depths; bars, channels, sailing ranges and directions; true meridian and compass variation, rocks, reefs, buoys, beacons, lights; tide establishment, detailed explanation of lighthouses and signal stations. They are carefully corrected for every substantial change in any of those features. They range in scale from $\frac{1}{100,000}$ (30·401 inches to the nautical mile) to $\frac{1}{1,000,000}$ ($\frac{1}{100}$ of an inch to the nautical mile), and comprise sailing charts exhibiting vast areas, general charts and coast charts for all coastwise navigation, and harbour charts on large scales. During the year ending June 30, 1888, there were distributed of coast and geodetic survey charts 41,327. Of Hydrographic Office charts there were in the same time distributed 23,814.

Charta, MAGNA. See MAGNA CHARTA.

Charte, a charter or system of constitutional law, embodied in a single document. The first such charter in France is known as the *Grande Charte*, or the Charter of King John (in 1355). But the constitution to which the term *Charte* is most frequently applied is that in which Louis XVIII. solemnly acknowledged the rights of the nation on his restoration in 1814. This *Charte* has ever since been considered the fundamental law of constitutional monarchy when that form of government has existed in France. A modification of it was sworn to, 29th August 1830, by Louis-Philippe, in which the sovereignty of the people is explicitly recognised. This *Charte* in its turn became a nullity by the revolution of February 1848.

Charter (Lat. *charta*; Gr. *chartē*, 'paper,' or 'anything written upon,' from *charasso*, 'I scratch' or 'write'). In its most general signification, charter is nearly synonymous with *deed* and *instrument* (see DEED), and is applied to almost any formal writing, in evidence of a grant, contract, or other transaction between man and man. In private law, its most important use is in the alienation of real estates, the writing given to the new proprietor by the old, in proof of the transference title, being usually called a charter. In public law, the name is given to those formal deeds by which sovereigns guarantee the rights and privileges of their subjects, or by which a sovereign state guarantees those of a

colony or other dependency (see CHARTE, MAGNA CHARTA). There is another sense of the term in which it is in a measure intermediate between the two we have mentioned—viz. where we speak of the charter of a bank or other company or association. In this sense it signifies an instrument by which powers and privileges are conferred by the state on a select body of persons for a special object (see BANK, CORPORATION, JOINT-STOCK COMPANY, &c.).

This is the general use of the term in the United States. It is a grant of authority from the state or the United States, creating a corporation, defining its powers, privileges, rights, and franchises. A charter of a private corporation, on the faith of which property has been given, is a contract within the meaning of the United States Constitution, Article I., sect. 10, which declares that no state shall make a law impairing the obligation of contracts. And while the state legislatures have no power to set aside or essentially modify charters that come within this prohibition, without the consent of the corporators, it is confined to transactions involving property and rights which may be asserted in a court of justice. This prohibition does not debar the state from exercising the right of eminent domain, nor prevent the exercise of its general police power. Charters of municipal and public corporations are not beyond legislative control; and the power to change and adapt them to the purposes for which they were created is implied in every enactment creating them. But most of the charters in the United States have in them a clause reserving to the state the power to alter, amend, or repeal them at pleasure. In some states the courts have power to grant charters to social, charitable, and religious organisations, while the state officers are authorised by law to grant charters for manufacturing, mining, railroad, and other corporations for purposes of trade.

Royal Charters, generally written in Latin, are of two kinds: I. Grants of lands, houses, honours, or liberties to persons who did not previously possess them; II. Charters confirming grants previously made, and therefore called 'Charters of Confirmation.' Confirmation charters are of three kinds: (1) Charters confirming previous grants, without reciting them; (2) Charters of simple confirmation, without addition of anything new; (3) Charters reciting previous charters and confirming them, with addition of something new. These last two classes of charters are called charters of 'Inspeximus,' or 'Vidimus,' from the word used by the granter in saying that he has seen the charter which he confirms. Royal charters generally contain seven clauses: (1) The 'Premises'—i.e. the name and style of the granter, the persons to whom the charter is addressed, the name and style of the grantee, the reason why the grant is made, and the description of the thing granted; (2) the 'Tenendum and Habendum'—i.e. the way in which the thing granted is to be held and had; (3) the 'Reddendo,' the return of rent or service which is to be made to the granter by the grantee; (4) the 'Quare Volumus,' or order that the grantee should have the thing granted, under certain penalties; (5) the 'Sealing' or 'Signature' clause, setting forth the seal, signature, or subscription by which the charter is authenticated; (6) the 'His Testibus,' or testing-clause, enumerating the persons present as witnesses to the granting of the charter; (7) the 'Date,' setting forth the time when, and the place where, the charter was granted.

A Charter in the law of Scotland is the written evidence of a grant of heritable property under the conditions imposed by the feudal law—viz. that the grantee, or person obtaining, shall pay at

stated periods a sum of money, or perform certain services to the granter, or person conferring the property. The granter of a charter, in virtue of the power which he thus retains over the property and its proprietor, is called the superior; and the grantee, in consequence of the services which he undertakes to render, the vassal; whilst the stipulated sum to be paid, or service to be rendered, is called the duty.

Charters are either *blench* or *feu*, from the nature of the service stipulated—*a me* or *de me*, from the kind of holding or relation between the granter and grantee; and original or by progress, from being first or renewed grants of the subjects in question.

Blench and Feu Charters.—The duty which the superior required of his vassal in former times was almost always military service, and the vassal was then technically said 'to hold ward'—to hold on condition of warding or defending his superior. But subsequent to the rebellion of 1745, in which the dangerous tendencies of the feudal relation were experienced, this holding was abolished (20 Geo. III. chap. 50), and the only duties which it has since been lawful to insert in charters are *blench* and *feu* duties. The former is a merely nominal payment—a penny Scots, a red rose, or the like, *si petatur tantum* (should it be asked); the latter is a consideration of some real value. Original *blench* charters having lost all object, and having no other effect but that of subjecting superiors to considerable expense in keeping up their titles, have become rare in modern practice. The forms of charters varying according to the circumstances in which they are granted, and the relations established between the granter and grantee, are of a highly technical nature.

The *Charter of Resignation* proceeds upon the formal surrender of the lands or other rights into the hands of the superior for the purpose of obtaining a new grant in favour of the resigner, with some change of the destination, or in favour of a purchaser or other disponent. This is termed a resignation *in favorem*. But when the property is surrendered in order to remain with the superior, the resignation is then said to be *ad remanentium*. In former times resignations were transacted with solemn formality by delivery of a staff or baton, as the symbol of surrender, into the hands of the superior, who, if the purpose was *in favorem*, returned the symbolic staff to the person to be invested with the lands, or to his attorney, the whole transaction being recorded in the form of a notarial instrument.

Crown charters of resignation or confirmation proceed upon the warrant of the Barons of Exchequer, as the royal commissioners in Scotland since the union of the crowns, for receiving resignations and granting new infeftments to crown vassals. The charter is preceded by the *signature* or order under the royal superscription, with consent of the barons, setting forth the terms in which the charter is to be expressed. After several other proceedings, the charter is finally completed by sealing. Previous to 1707 the Great Seal of Scotland was appended to crown charters, but by the treaty of union another seal was substituted. The royal charters of Scotland are recorded in the Register of the Great Seal, which is extant from about 1300 A.D., and continued to the present time. There are, however, numerous charters by the early Scottish kings not recorded in the Register, but extant in private collections and in the chartularies of religious houses. Ancient charters are usually remarkable for the excellence of their writing and the brevity and conciseness of their style. See Innes' *Lectures on Legal Antiquities*; Chassat's *Traité des Statuts*, &c.

(Paris, 1845); Bell's Law Dictionary; Menzies on Conveyancing.

Charterhouse (a corruption of *Chartreuse*, 'Carthusian') is the name of a famous hospital and school which occupied a joint-building in Charterhouse Square, London, till 1872, when the school was transferred to Godalming in Surrey. The Charterhouse was instituted in 1611 by Thomas Sutton, of Castle Camps, Cambridgeshire. The site had been occupied by a Carthusian monastery (founded in 1371), but on the dissolution of the monasteries by Henry VIII. it was made a place of deposit for his nets and pavilions. After undergoing many alterations, and passing into the possession of various distinguished persons, it was finally purchased from Lord Suffolk for £13,000 by Thomas Sutton, who endowed it with the revenues of upwards of twenty manors, lordships, and other estates in various parts of England. This 'masterpiece of Protestant English charity,' as old Fuller calls it, serves three uses—it is an asylum for poor brethren, an educational and a religious institution; hence Bacon terms it a 'triple good.' The *poor brethren* are eighty in number. None are admitted under fifty years of age, and only those who have been householders are eligible. Each brother has a separate apartment, a share of attendance from domestics, an ample though plain diet, and an allowance of about £36 a year for clothes and other matters, and four weeks' holiday every autumn. The brethren must be bachelors and members of the Church of England. Among the poor brethren in bygone years were Dryden's antagonist, Elkanah Settle; John Bagford, antiquary; Isaac de Groot, a descendant of Grotius; Alexander Macbean, who assisted Johnson in his Dictionary; John Grey, electrician; and—one could not omit him—Colonel Newcome.

There are thirty junior scholarships, worth £75 a year, open to all boys between twelve and fourteen years of age by public competition on conditions settled in accordance with the direction of the Public Schools Act (1868), the old system of direct nomination by the governors having been wholly abolished. There are also thirty senior scholarships, of £95 value, for boys of between fourteen and fifteen who have been at least a twelvemonth in the school; and five annual exhibitions of £80 for four years for boys leaving school. In addition to the scholars a large number of boys are sent to the Charterhouse because of its reputation. These either board with the masters or attend simply during the day. The number of extra boarders is now about 460. The institution is under the direction of the Queen, fifteen governors, and the master himself, whose salary from the foundation is £800 per annum. The hospital has now a separate governing body. Among the eminent persons educated in this establishment have been Isaac Barrow, Sir William (Judge) Blackstone, Addison, Steele, John Wesley, Bishop Thirlwall, George Grote, Thackeray, John Leech, and Sir Charles Eastlake. The new school at Godalming, designed by Hardwick, forms a large quadrangle, with a gatehouse tower 130 feet high, and a chapel rich in stained glass. The old school premises were sold to the Merchant Taylors' School, which is now installed here in handsome new school buildings erected in 1870-72. The quaint Charterhouse hospital and chapel still remain on the old site. The chapel contains Sutton's tomb. See Dr Haig Brown's *Charterhouse, Past and Present* (1879).

Charter-party (*charta partita*, there having been a custom in England and Aquitaine to write the instrument in duplicate on one piece of parchment, which was then divided by a straight line, so

that the parts should tally) is the common written form in which the contract of affreightment is expressed—viz. the hiring of the whole or part of a ship for the conveyance of goods. The case of carriage of passengers at sea is under different regulations. The carriage of goods is often left to rest on bills of lading, or even mere oral arrangement, but a charter-party with a sixpenny stamp is the proper and safe arrangement. It is executed by the owner or his accredited agent; abroad, the master has authority to sign. It identifies the ship by name, by tonnage measurement, and by place. The obligations of parties are generally expressed with fullness. The chief of these are that the ship is seaworthy, and is furnished with necessary tackle, and with a fit master and crew. Unseaworthiness may be caused by the manner of stowage. The master's knowledge of the particular ports and perils on the voyage is included in his fitness. The ship is also bound to have the proper papers and clearances. The ship must be ready to receive cargo at the time specified; and in general, delay on the part of the ship would entitle the charterer to cancel the contract. The voyage must be performed according to the rules of good seamanship, necessity being required to justify any deviation from the route. The matter of compulsory pilotage depends upon the Merchant Shipping Acts. Due care is to be shown in loading and unloading, and the goods must be safely delivered at the port of discharge. On the other hand the freighter must have a lawful cargo ready at the time agreed upon; in this case also delay would generally entitle the shipowner to cancel the contract, or at least to claim damages for detention. The freight is sometimes a lump sum for the voyage: sometimes so much per ton or per week.

The execution of a charter-party does not supersede the granting of Bills of Lading (q.v.) or receipts for the cargo, which are not only useful in fixing the condition and quantity of the goods, but are the documents of title by which the ownership of cargo may be transferred during voyage. In the case of general ships, which are advertised for a certain voyage, the shipowner becomes a common carrier, bound to carry goods tendered subject to the conditions of the advertisement, but in this case no charter-party is executed. In coasting voyages mere receipts, not formal bills of lading, are often used. In settling freight at the port of discharge, the weight or measurement of cargo there is *prima facie* the criterion, but it may be shown that the weight, &c. has altered during voyage. Where an advance against or prepayment of freight is made, the law of Scotland is that this may be recovered, even though the voyage fail; in England, on the other hand, both shipper and consignee are liable for freight, and the master has a lien on cargo for freight. But it is common under a *cesser* clause for the charterer to stipulate that his personal liability for freight and demurrage shall cease when the loading is completed, so that in most cases the master looks to his lien for security. When the goods arrive damaged, the consignee is bound to take them, and settle the freight subject to a claim for damages; he cannot abandon the goods for the freight. If the freighter take the goods at an intermediate port, the ship being unable to proceed further, a proportion of freight is due; and this is also the case where some of the goods are lost, if enough was not lost to justify abandonment. Except on a time charter, the duration of a voyage, which may depend on closing of navigation by ice, &c., is entirely at the risk of the shipowner. Dead freight is paid for unoccupied space in the ship where a full cargo has been promised. Apart from stipulation, the shipowner is liable for the goods shipped in their

original condition, except where that condition is altered by perils of the sea, hostile force, and inevitable accident. It is now common, however, by indemnity clauses in charter-parties to protect the owner from liability for every damage that can be covered by insurance. By statute, owners are not liable for fire, or for the fault of a compulsory pilot; and in no case are they liable beyond a sum representing £15 per ton of the ship's measurement. It is always an important question whether the arrangements made about the ship place the charterer in the position of an owner, or whether the owner retains such a possession and control of the ship as to be able to exercise a lien for freight, and on the other hand to incur liability for repairs and supplies, and for damages caused by negligence of the master or crew.

In the United States, the law relating to charter-parties is the same as that which has just been explained. When the charterer has complete control over the voyage, he is generally considered the owner for the voyage. But if the charter-party lets only the use of the vessel, the owner retaining possession and control over its navigation, the charterer is regarded as merely a contractor for a particular service, and the rights and duties of the owner are unchanged. The usual printed parts of a charter-party are construed like covenants in a deed, but charter-parties are often informal instruments, and are therefore construed as liberally as other mercantile contracts, preserving the intention of the parties. The courts incline to construe a charter-party as a contract for affreightment, charging the shipowners as carriers.

Charters Towers, a mining township of North-east Queensland, situated on the northern spurs of the Towers Mountain, 820 miles NW. of Brisbane. It dates from the gold discovery here of 1871-72, and was incorporated in 1877. It has railway connection with Townsville on the coast. Up till 1885 the gold-fields had yielded 1,316,221 ounces. Pop. of town, 3313; with district, 7310.

Chartier, ALAIN, one of the most noteworthy of early French writers, was born in 1390, and died in 1458. He lived at the court of Charles VI., to whom he acted as secretary. According to a famous story, Margaret, daughter of James I. of Scotland, Dauphine of France and herself a poetess, once stooped to kiss him as he lay asleep, in token of her admiration of his verses. His chief poetical piece is the *Livre des Quatre Dames*, which was written shortly after Agincourt, and in which four ladies alternately bewail the deaths of their lovers who fell in the battle. The sentiment of the poem is sincere, and the expression is often graceful and dignified. Chartier showed considerable skill in handling the *ballade* and other lyrical forms, but he is more interesting as a prose-writer than as a poet. In his own day he was known as the 'father of eloquence.' His chief prose works are *Le Curial*, an exposure of the vices of the court; *L'Espérance*, an attack on the corruption of the clergy; and the *Quadriloge Invecitif*, a noble appeal to Frenchmen to unite for the deliverance of their land from the foreigner. Chartier was a sincere patriot, and his writing often rises into grave and moving eloquence. He bravely espoused the cause of the oppressed labouring class, and he did much to re-animate his countrymen in their struggle with England. 'It is the eternal glory of Alain Chartier,' says M. Gêruzez, 'to have announced the mission of Jeanne d'Arc.' His writings summoned his countrymen to the task which they performed under the Maid of Orleans. He has not received the attention which he deserves. There is no better edition of his works than Duchesne's (1617). See mono-

graphs by Delaunay (1876) and Joret-Desclosières (1877).

Chartism, a movement in Great Britain for the extension of political power to the working-classes, rising out of widespread national distress and popular disappointment with the results of the Reform Bill of 1832. Before that period the middle classes had sought popular aid towards obtaining their own enfranchisement. The assistance was given, the people expecting to receive help in their turn. After the passing of the Reform Bill, agitation ceased for a time, and the members returned to parliament were indifferent, or opposed, to any further change in the political arrangements of the country. The middle classes were satisfied with their own success, and generally looked with small favour on projects for the further extension of political influence among the masses. Lord John Russell especially deprecated further change as a breach of faith with those who had carried the Reform Bill of 1832. This political discontent on the part of the workmen was greatly increased by the misery due to failing harvests and to a season of commercial depression which set in about 1837. Food became dear, wages fell, factories were closed, and work was scarce. The people associated their sufferings with their want of direct influence upon the government, and agitation for an extended franchise began.

In 1838 the representatives of the working-men drew up a programme embodying their views on political reform, and called the 'People's Charter.' Its six 'points' were: (1) Manhood suffrage; (2) equal electoral districts; (3) vote by ballot; (4) annual parliaments; (5) abolition of property qualification for members of the House of Commons; and (6) payment of members of parliament for their services. The programme thus drawn up was received with enthusiasm. Immense meetings, attended by enormous crowds of people, were held all over the country. The most prominent leader of the Chartist agitation was Feargus O'Connor, an Irishman, whose paper the *Northern Star* had a circulation of 50,000. Others were Attwood, Lovett, Stephens, Vincent, Ernest Jones, and Thomas Cooper. The mass of the working-men in the industrial centres supported the movement; and while many of them exclusively advocated an appeal to moral force, a great number insisted on violent methods. A body calling itself the National Convention, elected by the Chartists throughout the kingdom, met in London and afterwards in Birmingham in 1839. It proposed to the people various means of coercing the legislature into submission, recommending, among other things, a run on the savings-banks for gold, abstinence from excisable articles, exclusive dealing, and in the last resort, universal cessation from labour. During its sittings a collision took place with the military in Birmingham. Public meetings were forbidden, and alarming excesses were committed by the irritated mob. In June 1839 a petition in favour of the Charter was presented to the House of Commons signed by 1,280,000 persons. The House refused to name a day for its consideration, by a majority of 237 to 148, and the National Convention retaliated by advising the people to cease from work throughout the country. Fortunately, this advice was not followed; but the disturbances increased, and in November an outbreak at Newport, in Monmouthshire, took place, which resulted in the death of ten persons and the wounding of great numbers. For taking part in this wild insurrection, three of its leaders were sentenced to death, but their punishment was afterwards commuted to transportation. In 1842 great riots took place in the northern and midland districts, not directly originated by the Chartists, but encouraged

and aided by them after the disturbances began. It is a strong proof of the revolutionary spirit which animated the Chartists, that they opposed the agitation for the Repeal of the Corn Laws as a measure likely to make food cheap, to keep wages down, and thereby to benefit only the middle classes. In 1848 the Chartist movement came to a head through the agitation consequent on the revolution in France. Great uneasiness prevailed, especially at many of the industrial centres, and risings were feared. But the greatest demonstration of the movement took place in London, where a gigantic meeting on Kennington Common was announced for the 10th of April. It was to be attended by half a million of men, who were to carry to parliament a petition for reform signed by six million names. Such rumours excited great alarm. The procession was forbidden. Military measures were taken by the Duke of Wellington to prevent violence, and about 200,000 special constables were enrolled (amongst whom was Louis Napoleon, afterwards emperor). After all this preparation the demonstration proved a failure. Only 50,000 gathered on Kennington Common, and their leaders shrank from a conflict with the authorities. On examining the monster petition it was found that the signatures were fictitious to an unheard-of extent, yet the genuine ones amounted to nearly two millions.

Since 1848 Chartism has gradually died out. Its political principles were not new. The Duke of Richmond in 1780 introduced a bill into the House of Lords to give universal suffrage and annual parliaments, and earlier than this John Cartwright (q.v.) had advocated earnestly not only these but also vote by ballot. In 1780 Charles James Fox declared himself in favour of the identical six points which were afterwards included in the Charter. And in 1792 Grey, Erskine, Mackintosh, and many others, formed a 'Society of Friends of the People,' which aimed at obtaining a very large extension of the franchise.

But while the political side of Chartism was the most prominent, it should be recognised that the essence of it was economic and social. As one of its leaders said, it was a 'knife and fork question.' The movement was primarily due to economic suffering, and many of the remedies proposed were strongly socialistic in tendency. The reviving and increasing prosperity of the country after the collapse of Chartism in 1848 effectually prevented a return of the same spirit of discontent. This prosperity was due not only to the Repeal of the Corn Laws, but to the great industrial and colonial expansion of Britain which took a fresh start about the same time. Through the Reform Bills of 1867 and 1885, and the Ballot Act of 1872, the most important demands of the Charter have been substantially conceded. Industrial prosperity and political reform, with the development of trades-unions and of the co-operative system, have worked a decided change in the position of the working-classes as contrasted with their wretched lot in the period about 1840. See the articles on COOPER and O'CONNOR; Cooper's *Life, written by Himself*; Carlyle's *Chartism*; Kingsley's *Alton Locke*; Walpole's *History of England*; and McCarthy's *History of our Own Times*.

Chartres, the capital of the French department of Eure-et-Loir, 55 miles SW. of Paris, is built partly at the base and partly on the declivity of a hill overlooking the river Eure, which is here divided into two channels, one flowing within, and the other without the former ramparts, which are converted into agreeable promenades. It consists of an upper and lower town, connected by very steep streets; and the highest point is crowned by the glorious cathedral of Notre Dame—in Street's

opinion, the finest in France. Built chiefly between 1194 and 1260, it has two spires, of which the south-western is 342½ feet high, and the north-western, 371; the latter, built in 1607-14, being, 'on the whole, the most beautiful spire on the Continent.' Other features are the three rose-windows, the splendid portals, and the 13th-century stained-glass that fills no fewer than 130 windows. The church of St Pierre (12th century), the Porte Guillaume (14th century), and the obelisk to the memory of General Marceau, are also noteworthy. The weekly corn-market is one of the largest in France, and is remarkable as being under a corporation of women. It has manufactures of woollen, hosiery, and leather. Chartres usually gave the title of Duke to the eldest son of the Orleans branch of the Bourbons (see BOURBON). Pop. (1872) 19,322; (1886) 21,523.—The *Autricum* of the Carnutes (hence the present name), Chartres in 1594 was the scene of the coronation of Henry IV.

Chartreuse, LA GRANDE, the original Carthusian monastery, founded by St Bruno in 1084, is situated in the French department of Isère, 14 miles NNE. of Grenoble, in a wild and romantic valley, at an altitude of 4268 feet above the sea. The convent is a huge ungainly structure, dating mostly from the 17th century, earlier buildings having been several times destroyed by fire. The monks, who long manufactured a famous green, yellow, or white liqueur from various herbs, had at one time considerable property, but they were despoiled at the Revolution, being exiled from 1793 till 1816; and in November 1880 they declined to accept indulgence from the decrees for the expulsion of the religious orders. A remnant of monks still left received Queen Victoria and the Princess Beatrice on the occasion of their visit in 1887. Ruskin in part iv. of his *Præterita* (1888) describes his disappointment in both the monastery and its occupants. *Certosa* and *Charterhouse* are Italian and English forms of the French name. See CARTHUSIANS.

Chartulary means a collection of charters. So soon as any body, ecclesiastical or secular, came to be possessed of a considerable number of charters, obvious considerations of convenience and safety would suggest the advantage of having them classified and copied into a book or roll. Such book or roll has generally received the name of a Chartulary. Mabillon traces chartularies in France as far back as the 10th century, and some antiquaries think that chartularies were compiled even still earlier. But it was not until the 12th and 13th centuries that chartularies became common. They were kept not only by all kinds of religious and civil corporations, but also by private families. Many of them have been printed, and their contents generally are of the greatest value in historical, archaeological, and genealogical inquiries. The name is in Scotland applied to the record of feu-charters kept by the superior's law-agent.

Charybdis. See SCYLLA.

Chase, SALMON PORTLAND, American statesman, born at Cornish, New Hampshire, 13th January 1808, in 1830 settled as a lawyer in Cincinnati, where he acted as counsel for the defence of numerous fugitive slaves. An uncompromising opponent of slavery, his political course was for many years guided by the attitude of the two great parties towards this question. In 1841, foreseeing as little assistance from the Whigs as from the Democrats, he was largely instrumental in founding the Liberty party, which in 1844 brought about Clay's defeat. Chase was returned to the United States senate in 1849 by the Ohio Republicans, but separated from the party in 1852 when it

committed itself to slavery. He was twice elected governor of Ohio by the Republicans (1855-59), and in 1861-64 was secretary of the treasury. His management of the country's finances during these trying years has met with nothing but praise: taking office at a time when public credit was low, and the revenue barely adequate for the needs of the government in time of peace, he secured loans on reasonable terms, issued treasury notes ('greenbacks') bearing no interest, and obtained the establishment of national banks. In 1864 he was appointed by Lincoln chief-justice of the United States, in which capacity he presided at the trial of President Johnson (1868). Unsuccessful efforts were made to secure for Chase the Republican presidential nomination in 1860 and 1864, and the Democratic nomination in 1868. He died at New York, 7th May 1873. See his *Life* by J. W. Schuckers (1874).

Chasid'im (Heb., 'pious'), the name by which the Jewish party afterwards known as the Pharisees was first distinguished. The Chasidim first took definite form as a party in the course of the struggle between Judaism and Hellenism during and immediately before the Maccabean period. When in 167 B.C. the great majority of the Jewish people rose against their heathen masters, the Chasidim joined in the conflict, though separated from the other adherents of Judas Maccabeus as a closer community of those who were distinguished by especial 'piety'—i.e. especial strictness in the observance of the law. They took part in the struggle only so long as the freedom of religion was the question really involved; at a later time, when this was no longer the case, they seem to have withdrawn from it, for under Judas's brothers Jonathan and Simon (160-135 B.C.) they are not mentioned. Under Simon's successor, John Hyrcanus (135-105 B.C.), they appear for the first time in history under the name of Pharisees, and here we already find them in opposition to the family of the Maccabees or Hasmonaeans, with whom they had originally pursued a common interest. See PHARISEES.—The modern Chasidim are not, like those in the times of the Maccabees, marked by any peculiar spiritualistic tendency in religion, but rather by a strict observance of certain traditional forms and a blind subservience to their teachers. Their doctrine was promulgated in the middle of the 18th century by Israel of Podolia, called *Baal-Shem* ('Lord of the Name,' so called because he professed to perform miracles by using the great cabalistic name of the Supreme Being). Though condemned by the orthodox rabbis, this new teacher had great success in Galicia, and when he died (1760) left 40,000 converts. They are now broken into several petty sects; their religion is utterly formal, and its ceremonies are coarse and noisy.

Chasing. Metal casting and other raised metal-work, whether stamped or *repoussé*—i.e. hammered or punched up—may be defective in sharpness, or detail, or finish. When such defect is remedied by hand-cutting, as with a chisel or graver, such finishing is called chasing, but this term is not properly applied to the raising of the figures themselves. The backs of watches are sometimes elaborately chased in floral or other designs. When similar work is applied to flat surfaces, such as salvers for example, it is called either chasing or engraving. It was called *calatura* by the Romans; in modern Italian, *ceselatura*; in French, *ciselure*; in German, *ciselirung*—i.e. 'chiselling' in each case.

Charles, MICHEL, was born near Chartres on 15th November 1793. He entered the École Poly-

technique in 1812, and on leaving was classed among the engineers; but with rare generosity he renounced his place as an officer in order to assure a career to one of his unsuccessful comrades. In December 1829 he addressed to the Brussels Academy a memoir on two general principles of geometry, duality and homography. The introduction to this memoir expanded into the well-known *Aperçu historique sur l'Origine et le Développement des Méthodes en Géométrie*, the first edition of which was published in 1837. In 1841 he was appointed to the chair of Machines and Geodesy at the École Polytechnique, and in 1846 to that of Higher Geometry, which had just been instituted at the Sorbonne. In 1852 appeared his *Traité de Géométrie supérieure*; in 1860, *Les Trois Livres de Porismes d'Euclide rétablis pour la Première Foix*; in 1865, the *Traité des Sections Coniques*; in 1870, the *Rapport sur les Progrès de la Géométrie*. These, his principal works, are geometrical and historical. His contributions to the *Comptes rendus* of the Academy of Sciences and to other scientific publications are extremely numerous, and though in the main geometrical, are not exclusively so. In particular he treated in several memoirs the question of attraction, and gave the first synthetic demonstration of a celebrated theorem of Maclaurin on the attraction of ellipsoids. Two of his memoirs on the properties of cones of the second degree, and on the spherical conics, were translated into English, and published, with additions, by Charles Graves in 1841. The best account of Charles's writings is that given by himself in the *Rapport* above mentioned. During his long life he was the recipient of many scientific distinctions, and he will always be cited as one of the great geometers of the present century. He died at Paris on 18th December 1880. An unfortunate episode in his life was that of the autographs. In 1867 he reported to the Academy that he had come into possession of autographs of Pascal's which proved that Pascal had anticipated Newton's greatest discoveries. Ultimately, however, he had to admit that these and about 27,000 other autographs (including letters from Julius Cæsar, Dante, and Shakespeare) were forgeries. The forger, Irène Lucas, was convicted and punished.

Charles, PHILARÈTE, a voluminous French writer, was born at Mainvilliers, near Chartres, 8th October 1798. Early imbued with Rousseau's ideas by his father, an old Jacobin, he was apprenticed at fifteen to an ardent Jacobin bookseller, along with whom he was sent to jail after the Restoration. Released by Chateaubriand's influence, he went to England, where he found employment in a bookseller's shop, and during his seven years' residence laid the foundation of his large knowledge of English literature. After his return to France he contributed reviews of English books to the *Revue encyclopédique*. In 1824 his *Discours sur Jacques Auguste de Thou*, and in 1828 his *Tableau de la Langue et Littérature Française, 1500-1610*, were crowned by the Academy. In 1837 Charles became librarian of the Bibliothèque Mazarin, and in 1841 professor of Northern Languages at the Collège de France, which chair he filled until his death, at Venice, July 18, 1873. Besides showing indefatigable activity as a journalist, he published books on Charles I., Cromwell, the middle ages, the 16th century in France, and studies on Spain, on Germany, on the 18th century in England, 19th-century manners, Shakespeare, Mary Stuart, and Aretino. His *Mémoires* fill two volumes (1876-78).

Chassé, DAVID HENDRIK, BARON, a famous Dutch soldier, was born at Thiel, in Guelders, March 18, 1765, began his military career when but ten

years of age, became a lieutenant in 1781, and captain in 1787. After the failure of the revolutionary movement he took French service; was appointed lieutenant-colonel in 1793; and two years later found himself marching towards the Netherlands under the command of Pichegru. He afterwards fought with the French in Germany and Spain, gaining great distinction, and from Napoleon himself, from his fondness for bayonet charges, the name of 'Général Baïonette.' He was made a baron by Louis Bonaparte in 1809. As lieutenant-general of the Dutch forces in 1815 Chassé did good service at Waterloo against his old comrades, the French. As governor of Antwerp he covered himself with glory by his heroic three-weeks' defence of the citadel with 5000 men against 60,000 Belgians and French (1832). He died at Breda, May 2, 1849.

Chassepot, ANTOINE ALPHONSE, French inventor, born 4th March 1833, was an employee in the Paris arsenal of St Thomas, where he became an official in 1858, and in 1863 brought before the government the model of his rifle, adopted three years afterwards. See BRECH-LOADING, RIFLE.

Chasseurs (Fr., 'hunters') is a name used since 1741 for certain *corps d'élite* of the French army. The *Chasseurs-à-cheval* and the *Chasseurs d'Afrique* are light cavalry. The latter were raised in 1831 for service in Africa, mounted on Arab horses, and wearing a distinct uniform. There were in 1888 twenty regiments of *Chasseurs-à-cheval*, and four of *Chasseurs d'Afrique*. Uniform, sky-blue tunic with red trousers. The *Chasseurs-à-pied* are light infantry corresponding to the Rifle Corps of the British and the *Jägers* ('hunters') of the German and Austrian armies. One regiment, the *Chasseurs de Vincennes*, formed in 1838, has always been especially famous for rapidity and precision of movement, as well as accuracy of fire. There are now thirty battalions of *Chasseurs-à-pied* in the French army. Uniform, dark-blue tunic and iron-gray trousers instead of red.

Chastelard, PIERRE DE BOSCOSEL DE, a hapless French poet, born in Dauphiné about 1540, became a page in the household of the Constable Montmorency, afterwards in that of the Marshal Damville, and accompanied the latter to Scotland in his escort of Queen Mary' (1561). Here he fell madly in love with the queen, and Mary was indiscreet enough to amuse herself with his passion, receiving without displeasure the amorous verses which the poet laid before her. Misinterpreting the goodwill of the queen, Chastelard ventured to conceal himself under her bed, was discovered and forgiven, but on a repetition of his offence at Burntisland early in 1563, where the queen was resting on her journey to St Andrews, was seized and executed on the following morning. He is the subject of a tragedy, the first of the trilogy devoted by Mr Swinburne to the history of Mary.

Chaste Tree. See VITE.

Chasuble (Lat. *casula*, *casubula*, and *casibula*; also *penula*, *planeta*; Gr. *phelonion* or *phainolēs*), the uppermost garment worn by priests in the Eastern and the Roman Catholic Church when robed for the celebration of the mass; having been at first a secular garment of ceremony common to both sexes. When adopted as an ecclesiastical robe, it was for some centuries used by all grades of the clergy, even as low as that of the acolytes, and its earliest restriction to priests appears in Canon xxviii. of the Fourth Council of Toledo, in 633 A.D. It was called also 'the Vestment,' though this term more properly denotes collectively all the robes worn at mass, of which the chasuble is the principal item. Originally it cov-

ered the priest from head to foot, like a little house, whence some writers think it had its name of *casula* (Isid. Hispal., *Orig.* xix. 24).

The earliest direct evidence for it as a sacerdotal robe is in the mosaics of San Vitale at Ravenna (547 A.D.), where Archbishop Maximian is depicted wearing it. Rich materials, cloth of gold or silver, silk, and velvet, elaborately embroidered, were used for it. In the middle ages it was of an elliptical shape, like a *vestia piscis*, with a hole in the middle for the head; it had no sleeves. When put on it showed two peaks, one hanging down before; another, on which a cross was embroidered, hanging down behind, though in Italy the cross was and is usually in front. The Greek chasuble is ampler and rounder than the Latin form, having more the nature of a mantle, and the episcopal chasuble is provided with a pattern of crosses. Archbishops do not wear the chasuble, but another vestment named *Sakkos*, which is worn by bishops also in Russia. The modern Latin form is commonly a parallelogram with rounded angles, or else resembles a violin. In the Reformed Church of England the chasuble was enjoined as the celebrant's robe at Holy Communion by the Prayer-book of 1549, prohibited by that of 1552, but again legalised in 1559. It remained, however, in practical abeyance (its place in cathedrals and on solemn occasions being supplied by the cope) till recent times, when its use has been partially revived, first in 1851 at St Thomas the Martyr in Oxford. In France the press or wardrobe in which chasubles were kept was called the *chasublier*.

Chat (*Saxicola*), a genus of small birds in the Thrush family (Turdidae). The bill at the base is broader than its height, and the upper portion is not hooked. The genus includes some thirty-six species, especially at home in northern temperate regions, frequenting dry stony places, and nesting in holes. They are lively birds, flitting about rapidly and untiringly in pursuit of insects, on which they chiefly feed. The Wheatear (*S. cyanus*) is a good example, found in Europe, North Africa, and North America, and along with other chats frequent in Britain. Yellow-breasted Chat is a popular name for a bird common in the United States, and technically known as *Icteria virens*.

Chata (*Pterocles alchata*), a desert fowl of the nature of a grouse, occurring in waste places in Southern Europe, North Africa, Arabia, and Syria. It is very good to eat, and large numbers are shot.

Château, CHÂTEL, or CASTEL, from the Lat. *castellum*, 'a fort,' enters as a component part into many names of places in France. See CASTLE. A 'château en Espagne' is a castle in the air.

Chateaubriand, FRANÇOIS RENÉ, VICOMTE DE, a distinguished French writer and politician, was born at St Malo, in Brittany, on September 4, 1768. He belonged to a noble Breton family, and was the youngest of ten children. His early years were spent partly by the sea at St Malo and partly in the seclusion of the woodland château of Combourg. He was educated at Dol and Rennes, and served for a short time as an ensign in the

Chasuble.

regiment of Navarre. In 1791 he sailed to North America, and spent eight months there in the travels which are recounted in his *Voyage en Amérique*. On hearing of the arrest of Louis XVI. he returned to France and joined the army of the émigrés. During the Prussians' retreat he was left behind for dead near Namur, but contrived to make his way to that town, and thence, with no little difficulty, to England. For some years he maintained himself in London by teaching and writing translations; in 1797 he published an *Essai sur les Révolutions*, and in 1800 he was enabled to return to France. *Atala*, a love-story of savage life, the scene of which is laid in the American forests and prairies, appeared in 1801, and established Chateaubriand's literary reputation. The *Génie du Christianisme* (1802), a vindication of the Church of Rome, raised him to the foremost position among the French men of letters of the day. He was neither a sound thinker nor a skilful controversialist, and the merit of his famous treatise lies almost entirely in its brilliant passages of description. These, however, are often curiously out of place in a work of the kind. Sainte-Beuve, who spoke of the *Génie* as a *coup de théâtre et d'autel*, declared that many of them would have been more warrantably included in a *Génie du Paganisme*. But the book appeared when there was a widespread reaction against scepticism, and its eloquent pleadings were favourable to the conciliatory policy which Napoleon had adopted in regard to the pope. Its success in consequence was enormous. Its author was in 1803 appointed secretary to the embassy at Rome, where he wrote his *Lettres sur l'Italie*, and in 1804 was sent as ambassador to the little republic of Valais. But on the murder of the Duc d'Enghien, Chateaubriand refused to hold office under Napoleon. He set out to the East in 1806, visited Greece, Palestine, and Egypt, and returned to France in 1807. Two years later he issued *Les Martyrs*, a prose epic, of which the action passes in the days of Diocletian. There is much that is false, much that is extravagant in this singular book, and the borrowed epical machinery works clumsily throughout. But there is genuine passion in the episode of Velleda; and in calling up a vision of the beauty of the ancient world the writer exhibits an almost unsurpassable mastery of ornate prose. In 1814 Chateaubriand published a pamphlet, *De Bonaparte et des Bourbons*, which Louis XVIII. declared to be worth an army to the Legitimist cause. From 1814 to 1824 he gave a thorough-going support to the Restoration monarchy. He was made a peer and a minister of state, and from 1822 to 1824 held the post of ambassador extraordinary at the British court. It was his ambition to become the guiding power in French politics; he believed that it lay in him to reconcile Legitimism and liberty. He was disappointed, however, in his hope of becoming prime-minister, and from 1824 to 1830 he figured as a Liberal politician. On the downfall of Charles X. he refused to swear allegiance to Louis-Philippe, and went back to the Royalist party. His changes of front were not due to mere selfish ambition. A Breton noble, he was by his birth and associations a Royalist; his writings prove that he was deeply imbued with the anti-social sentimentalism of Rousseau (he claimed Byron as his pupil); he had almost no logical faculty, and he was by temperament imperious and rebellious. 'In natural disposition,' he wrote in 1831, 'I am still a Republican.' His politics were thus a tissue of inconsistencies, but to regard him as a mere time-server is to misunderstand his character. During the reign of Louis-Philippe he withdrew from public affairs, and occupied himself in preparing his *Mémoires*

d'outre Tombe for posthumous publication. Parts of this eloquent autobiography appeared, however, before his death, which occurred on July 4, 1848. Besides those mentioned above, his writings include the *Itinéraire de Paris à Jérusalem*; *Les Natchez*, a prose epic dealing with savage life in North America; and two works of fiction, *René* and *Le Dernier des Abencérages*.

Chateaubriand is a writer whom it is difficult to criticise justly. He was not a thinker, and he produced no book which has the unity and sustained excellence of an enduring work of art. He dealt in false sentiment and extravagant imagery; he was blind to the virtues of simplicity and restraint. Sainte-Beuve said he transferred the capital of prose from Rome to Byzantium and introduced the style of the lower empire. But when he is at his best his brilliant and glowing diction acts on the reader like an enchantment. His writings revealed new capabilities in the French language. There is no French author of earlier date whose prose can compare with Chateaubriand's in the power of conveying the beauty and mystery of nature. His style, with its magical play of colour, its cunning felicity of descriptive phrase, was a new thing in French literature. It fascinated readers accustomed to the cold and polished prose of the classical school, and marked the beginning of a new literary epoch. Chateaubriand has been justly called the father of the romantic school, and the beauty and grandeur of his finest descriptive passages have been surpassed by none of his followers. See Sainte-Beuve's *Chateaubriand et son Groupe Littéraire* (2 vols. 1877).

Châteaubriant, a town in the French department of Loyer Loire, on the Clère, 40 miles NNE. of Nantes by rail, with several old churches and a castle, iron-founding and bell-casting, and productive iron-mines close by. Pop. 5150.

Châteaudun, a pretty town in the French department of Eure-et-Loir, on the Loir, a tributary of the Loire, 83 miles SW. of Paris by rail. It was almost destroyed by fire in 1723, and on 18th October 1870 was captured by the Germans after an obstinate resistance. Dunois is buried in the chapel of the stately castle. Pop. 6709.

Château Gaillard. See ANDELYS.

Château-Gontier, a town in the French department of Mayenne, on the Mayenne, 180 miles WSW. of Paris by rail. It has linen and woollen manufactures. Pop. 7334.

Château Margaux. See MARGAUX.

Châteauroux, the capital of the French department of Indre, on the left bank of the river Indre, 88 miles S. of Orleans by rail. It has manufactures of woollens, iron, leather, and tobacco. General Bertrand was born and died here, and a statue was erected to him in 1854. Pop. (1872) 16,858; (1886) 21,995.

Château-Thierry, a town in the French department of Aisne, 59 miles E. by N. of Paris by rail, with manufactures of mathematical and musical instruments, dye-works, and quarries. It has the ruins of an old castle (720), and is the birthplace of Lafontaine; here, too, Napoleon defeated the Prussians and Russians, 12th February 1814. Pop. 6405.

Châtelaine, the wife of the châtelain or Castellan (q.v.), the commander of a feudal castle. A *chaîne châtelaine* or simply *châtelaine*, a chain such as a lady châtelaine might wear (cf. the English *housewife*), is a chain depending from the waist, to which are attached keys, scissors, &c.

Châtelard. See CHASTELARD.

Châtelet-Lomont, GABRIELLE ÉMILIE, MARQUISE DU, a very learned Frenchwoman, notorious

for her intimacy with Voltaire, was born at Paris, 17th December 1706. At an early period she displayed a great aptitude for the acquisition of knowledge. She studied Latin and Italian with her father the Baron de Breteuil, and subsequently betook herself with zeal to mathematics and the physical sciences. Distinguished alike for her beauty and talent, she soon found a host of suitors for her hand. Her choice fell on the Marquis du Châtelet-Lomont, but her marriage did not hinder her from forming, in 1733, a *tendresse* for Voltaire, who came to reside with her at Cirey, a château on the borders of Champagne and Lorraine, belonging to her husband. Here they studied, loved, quarrelled, and loved again, for several years. In 1747, however, she became 'not insensible to the brilliant qualities' of a certain M. Saint-Lambert, a captain of the Lorraine Guards; and the result was, that the philosopher had to make room for the soldier, and content himself for the future with being the 'devoted and indulgent friend' of his former mistress. She died at Lunéville, 10th September 1749, a few days after having given birth to a child. Her first writing was *Institutions de Physique* (1740), a treatise on the philosophy of Leibnitz. She also translated the *Principia* of Newton into French, accompanying it with algebraic elucidations. It did not, however, appear till 1756. See VOLTAIRE, and the Life of the Marquise by Capeligue (1868).

Châtellerault, a town in the French department of Vienne, on the river Vienne, 40 miles S. of Tours by rail. A handsome stone bridge, with a gateway built by Sully at one end, connects it with a suburb on the other side of the river. It is a smoky, dingy place, one of the chief seats of the cutlery manufacture in France, and since 1820 has had a government small-arms factory. Its river-port makes it the entrepôt for the produce of an extensive district. The title of Duke of Châtellerault was conferred by Henry II. in 1548 on James Hamilton, Earl of Arran and Regent of Scotland; and it now is claimed by both the Duke of Abercorn and the Duke of Hamilton—by the latter under an imperial decree (1864) of Napoleon III. Pop. (1872) 13,360; (1886) 14,498.

Chatham (Saxon *Ceteham* or *Cwetham*, 'village of cottages'), a parliamentary borough, river-port, fortified town, and naval arsenal, in the county of Kent, situated on the right bank of the Medway, at the upper part of its estuary, 30 miles ESE. of London. It forms almost one continuous town with Rochester (q.v.) on the west, but itself has few objects of interest, being much of it ill built and irregular, although great improvements have been effected in recent years. The High Street is 1½ mile long, parallel to the river. Chatham owes its importance to its naval and military establishments situated at Brompton, a suburb on high ground overlooking the Medway. There is also a large convict establishment. The Chatham fortified lines are the frequent scenes of field-operations, imitation battles, and reviews. Pop. (1851) 28,424; (1871) 45,792; (1888) 47,634. The borough sends one member to parliament. Traces of Roman villas have been found, with Roman bricks, tiles, coins, and weapons. The dockyard was founded by Elizabeth before the threatened invasion of the Spanish Armada. In 1662 it was removed to its present site. In 1667 the Dutch, under De Ruyter, sailed up the Medway, and, in spite of the fire from the castle, destroyed much shipping and stores.

In a military point of view, the lines of detached forts connected with Chatham constitute a fortification of great strength; and the whole is regarded as a flank defence for London in the event of an

invader seeking to march on the capital from the south coast. In 1888 an additional chain of forts was being built by convict labour over a wider area. The place is also defended by some strong forts on the Medway. In and near Chatham are Fort Pitt, a military hospital and strong fort; Melville Hospital, for marines and sailors; barracks for infantry, marines, artillery, and engineers; a park of artillery; and magazines, storehouses, and depôts on a large scale.

Chatham is one of the principal royal ship-building establishments in the kingdom, and a visit to it never fails to impress the stranger with a sense of the naval power of England. The dockyard is nearly two miles in length, containing several building-slips, and wet-docks sufficiently capacious for the largest ships; and the whole is traversed in every direction by tramways for locomotives, with a gauge of 18 inches. Three great wet-docks on reclaimed marsh land were completed in 1883 after the labour of 17 years, and at a total cost of about £3,000,000 (including cost of site; as also convict labour valued at £400,000). The reclaimed land extended to 400 acres; and the aggregate water area of the three new wet-docks is 67 acres. A duplicate of Brunel's block-making machinery is kept at Chatham to supplement that at Portsmouth. The dockyard is controlled by an admiral-superintendent. The actual workmen, artisans and labourers, vary in number according to the amount of shipbuilding and repairing going on. In the navy estimates provision is made for about 5000 artisans and labourers. A statue of Lieutenant Waghorn, a native of Chatham, and the pioneer of the 'overland route' to India, has been erected near the railway station; but Chatham's most cherished memories are of Charles Dickens.

Chatham, (1) a town of Ontario, on the Thames, 67 miles SW. of London by rail, with a number of mills and foundries, soap and candle works, and an active trade in grain, pork, and wood. Pop. 5873.—(2) A port of entry in the north of New Brunswick, on the Miramichi, 6 miles NE. of Newcastle, with a good harbour, ship-yards, foundries, a Catholic cathedral, and a college. Pop. 3000.

Chatham, WILLIAM PITT, EARL OF, sometimes styled PITT THE ELDER, one of the greatest English orators and statesmen of the 18th century, was the younger son of a country gentleman, Robert Pitt of Boconnoc, in Cornwall, and was born November 15, 1708. After an education at Eton and Oxford, he travelled on the Continent, and on his return obtained a cornetcy in the Blues. In 1735 he entered parliament for Old Sarum—that synonym for electoral corruption—a borough then belonging to his family. He espoused the side of Frederick, Prince of Wales, then at deadly feud with the king, and offered as the leader of a number of young discontented Whigs known as the 'Patriots' a determined opposition to Walpole, who was at the head of affairs. He was deprived of his commission in consequence—an insult and injury which only increased the vehemence of his denunciations of the court and the government. His influence, both in and out of the House of Commons, increased rapidly; and Walpole being driven from power in 1742, the king, notwithstanding his hatred of Pitt, found it necessary, four years later, to allow of his admission to a subordinate place in the Broad Bottom administration; subsequently he was appointed to the lucrative office of paymaster-general. The Duchess of Marlborough, pleased with his patriotism and powers of oratory, left him £10,000; and later, Sir William Pynsent, struck with similar admiration, left him his whole property, amounting to some £3000 a year, and including what became the family place of the Pitts in Somersetshire. In

1755, when Henry Fox (afterwards Lord Holland) was made secretary of state, finding himself opposed to the foreign policy of the new minister, Pitt resigned office as paymaster. In the following year, when the king, unwillingly acceding to popular demands, had to dismiss Fox, Pitt became nominally secretary of state, but was virtually premier. He immediately began to put into execution his own plan of carrying on the war with France, and inaugurating a brilliantly successful foreign policy. He raised the militia and strengthened the naval power; but the king's old enmity and German predilections led him to oppose Pitt's policy, who thereupon resigned office in April 1757, but was recalled in June, in obedience to the loud demands of the people.

Now firmly established in power, Pitt's war policy was characterised by unusual vigour and sagacity. Success returned to the British arms. French armies were beaten everywhere by Britain and her allies—in India, in Africa, in Canada, on the Rhine—and British fleets drove the few French ships they did not capture or destroy from almost every sea. But the prime mover of all these brilliant victories found himself compelled to resign (1761), when, on the accession of George III., and owing to the influence of Lord Bute, an attempt was made to introduce a vacillating policy into the government; his immediate cause of resignation being the refusal of the majority of the cabinet to declare war with Spain, which Pitt, foreseeing as imminent, wished to commence before the Spaniards were thoroughly prepared. As some recompense for his important services Pitt received a pension of £3000 a year; and his wife, sister of George Grenville, was created Baroness Chatham. Until 1766 Pitt remained out of office, not offering a factious opposition to government, but employing all his eloquence to defeat some of its most obnoxious measures. In that year he received the royal commands to form a ministry. He undertook the task, choosing for himself—to the astonishment of the public, and the sacrifice, to a considerable extent, of his popularity—the almost sinecure office of Privy Seal, with a seat in the House of Lords as Viscount Pitt and Earl of Chatham. Ill-health prevented Chatham from taking any active part in this ministry, of which he was nominally the head, and which was weak and embarrassed throughout, and he resigned in 1768, to hold office no more. He did not, however, cease to take an interest in public affairs. He spoke strongly against the arbitrary and harsh policy of government towards the American colonies, and warmly urged an amicable settlement of the differences. But when, America having entered into treaty with France, it was proposed by the Duke of Richmond to remove the ministers, and make peace on any terms, ill though he was, Chatham came down to the House of Lords. In a powerful address he protested against the implied prostration of Britain before the throne of the Bourbons, and declared that war, with whatever issue, would be preferable to the proposed terms of peace. This address secured a majority against the motion, and the war was continued. But it was the orator's last effort; for, exhausted by speaking, on rising again to reply to a query addressed to him by the Duke of Richmond, his physical powers suddenly failed, he fell back into the arms of his friends, and was carried by his second son, William, less than five years later himself prime-minister, from the House. He died May 11, 1778. He was honoured with a public funeral in Westminster Abbey, where a statue was also erected to his memory at the public expense; and in addition, government voted £20,000 to pay his debts, and conferred a pension of £4000 a year

on his descendants. Chatham's personal appearance was dignified and imposing, and combined with a voice of the most magnificent compass, added greatly to the attractions of his oratory, which was of the most powerful kind. It is said that even his whispers were, when he pleased, distinctly heard outside the House in the lobby. His upright and irreproachable character demanded the admiration of his enemies; but his affectedness and haughtiness not unfrequently disgusted his friends, and pride rather than principle seems to have actuated his course at some important conjunctures of his life. He had, however, an intense love of country; the grand object of his ambition being to make his native land safe against all contingencies, and powerful among nations. See his *Life* by F. Thackeray (2 vols. 1827), and his *Correspondence* (4 vols. 1838-40).

Chatham Islands, a small group in the Pacific, lying 360 miles E. of New Zealand, to which they politically belong. They are the antipodes of Toulouse in France. There are three islands—of which the largest, Chatham Island, is 25 miles long—and some rocky islets. Total area, 375 sq. m.; pop. (1886) 394, of whom 159 were Maoris, and 36 Morioris or aborigines. The Chatham Islands were discovered in 1791 by Lieutenant Broughton, of the brig *Chatham*. A large brackish lake occupies the interior of Chatham Island, which is of volcanic origin and hilly. Stock-rearing and seal-fishing are the chief industries, the islanders having in 1886 no fewer than 63,650 sheep and 670 cattle, with which they supply passing whalers. Timber of any size is unknown, so that the native canoe is merely wicker-work bound together by cordage of indigenous flax. The Morioris numbered 1200 in 1831, when 800 Maoris were landed from New Zealand, by whom the former were reduced to 90 in nine years' time.

Chatl, a small leopard-like cat, smaller than an ocelot, found in South America.

Châtillon, a town in the French department of Côte d'Or, on the Seine, 49 miles NNW. of Dijon. A congress of allied sovereigns was held here in 1814, from February 5 to March 19, and opened fruitless negotiations with Napoleon respecting conditions of peace. Pop. 5120.

Chat Moss, a bog in Lancashire, the largest in England, 7 miles W. of Manchester, and 10 sq. m. in extent. It is celebrated as having in 1793-1800 been the scene of the first great and successful efforts for the reclaiming of bogs, largely through the instrumentality of Roscoe the historian, and in 1829 of one of George Stephenson's great engineering triumphs in the construction of the Liverpool and Manchester Railway. It is very slightly elevated above the sea, and from 20 to 30 feet in depth. Stephenson laid branches of trees and hedge-cuttings, and in the softest places rude hurdles interwoven with heather, on the natural surface of the ground, containing intertwined roots of heather and long grass; a thin layer of gravel was then spread above all, and on it the sleepers, chairs, and rails were laid in the usual manner. Drains were at the same time cut on both sides of the line, and in the central part of the moss a conduit was formed beneath the line of railway of old tar-barrels placed end to end. Notwithstanding difficulties which every one but himself deemed insuperable, Stephenson constructed the portion of the line through Chat Moss at a smaller expense than any other part of the railway. See *Bog*.

Chatsworth, the magnificent seat of the Duke of Devonshire, one of the most splendid private mansions in England, is situated in Derbyshire, on the Derwent, 25 miles N. by W. of Derby. The

domain was purchased by Sir William Cavendish, who in 1553 began the old mansion, which, after his death in 1557, was completed by his widow, 'Bess of Hardwick,' afterwards Countess of Shrewsbury. Here Mary, Queen of Scots, was five times imprisoned during 1573-81. The present edifice includes the old Palladian pile built in 1687-1706 by the first Duke of Devonshire, and the north wing added in 1820. The façade is 720 feet long, or with the terraces, 1200 feet. The building is nearly a square, with an inner quadrangle. Chatsworth is famed for its library, and for its pictures and sculptures by Holbein, Titian, Teniers, Murillo, Reynolds, Landseer, Canova, Thorwaldsen, Chantrey, &c. "The gardens and park, 10 miles in circuit, offer an exquisite variety of hill and dale. They were laid out by Loudon and Paxton, and are celebrated for their trees, shrubs, rockwork, deer, and water-works—only surpassed by those at Versailles. The conservatory, unrivalled in Europe, covers nearly an acre, measures 300 by 145 feet, is 65 feet high, and has 70,000 square feet of glass, with a carriage-road through it. Hobbes, the philosopher, lived much at Chatsworth. See CAVENDISH.

Chattahoo'chee, a headstream of the Appalachicola (q. v.).

Chattanooga, capital of Hamilton county, Tennessee, a shipping centre on the Tennessee River, 151 miles SE. of Nashville, with good railway connections. The town has cotton and other manufactories, ironworks, tanneries, and sawmills. There was much fighting near here early in the civil war. Pop. (1870) 6093; (1880) 12,892.

Chattel (Old Fr. *chatel*, from Low Lat. *capitale*, meaning the capital or principal sum in a loan; hence goods in general, especially cattle, as distinguished from land), in the law of England, is a term used to designate any kind of property which, with reference either to the nature of the subject or the character of the interest possessed in it, is *not freehold*. Ownership in personal or movable property is generally absolute. Any estate or interest in lands and tenements not amounting to freehold is a chattel. But as, between property thus 'savouring of realty' and mere personal movables—money, plate, cattle, and the like—there was a manifest distinction, chattels were, consequently, distinguished into *chattels-real* and *chattels-personal*. These classes of property differ considerably as to the method of holding and transferring them and their devolution on death. See REAL AND PERSONAL PROPERTY.

Chatterer, a significant popular name, often applied to the birds of a small family (Ampelidæ) of finch-like Perching birds (Insessores). The short broad beak with only a hint of a hook, the soft plumage, and tolerably long wings are characteristics of the family. Only about nine species, of small size, are known, and confined to the warmer parts of the nearctic and palaearctic regions. The Bohemian Waxwing (*Ampelis garrulus*), living in the north of Europe, Asia, and America, but coming south in winter, sometimes in vast numbers, and the Cedar Bird of America are the best-known examples. See WAXWING.

Chatterton, THOMAS, was born at Bristol, 20th November 1752. His father, a sub-chanter in the cathedral, and master of a charity school, was a roystering fellow, yet a lover of books and coins, a dabbler in magic; he had died in the August before the poet was born. The mother, a poor schoolmistress and needlewoman, brought up her boy and his sister beneath the shadow of St Mary Redcliffe, that glorious church where their forefathers had been sextons since the days of Elizabeth. He seemed a dull, dreamy child till his seventh year; then he 'fell in love' with an old

illuminated music folio, and, quickly learning to read from a black-letter Bible, began to devour every book that fell in his way. He was a scholar of Colston's bluecoat hospital from 1760 till 1767, and then he was bound apprentice to Lambert, an attorney. In December 1762 he wrote his first poem, *On the Last Epiphany*; in the summer of 1764, the first of his pseudo-antiques, *Elinour and Juga*, which imposed on the junior usher of his school, and which he professed to have got from Canynge's Coffin in the muniment room of St Mary's. Next, early in 1767, for one Burgum, a pewterer, he concocted a pedigree of the De Bergham family (this brought him five shillings); and in 1768 he hoaxed the whole city with a description, 'from an old manuscript,' of the opening of Bristol Bridge in 1248.

His life at Lambert's was a sordid one; he slept with the footboy, and took his meals in the kitchen. Yet, his duties over—and he discharged them well—he had ample leisure for his darling studies, poetry, history, heraldry, music, antiquities. An attempt to draw Dodsley had failed, when, in March 1769, he sent Horace Walpole a 'transcript' of *The Ryse of Peyncteynge, written by T. Rowlie, 1469, for Mastre Canynge*. Walpole, quite taken in, wrote at once to his unknown correspondent, expressing a thousand thanks for the manuscript, deploring his ignorance of the 'Saxon language,' and half offering to usher the Rowley poems to the world. Back came a fresh batch of manuscript, and with it a sketch of Chatterton's own history. The poems, however, being shown to Mason and Gray, were pronounced by them to be forgeries; and Walpole's next letter was a letter of advice, to stick to his calling, that so, 'when he should have made a fortune, he might unbend himself with the studies consonant to his inclinations.' A curt request for the return of the MSS. lay six weeks unanswered during Walpole's absence in Paris. A second, still curter; and, 'snapping up poems and letters,' Walpole 'returned both to him, and thought no more of him or them'—until, two years after, Goldsmith told him of Chatterton's death.

Was it jest or grim earnest, a boyish freak or a suicide's farewell, that 'Last Will and Testament of Thomas Chatterton . . . executed in the presence of Omniscience this 14th of April 1770?' Anyhow, falling into his master's hands, it procured the hasty cancelling of his indentures; and ten days later the boy quitted Bristol for London. There he arrived with his poems, and perhaps five guineas in his pocket, and lodged first at one Walmsley's, a plasterer, in Shoreditch; next, from the middle of June, at Brooke Street, Holborn. Abstemious, sleepless, he fell to work as with a hundred hands, pouring forth satires, squibs, stories, political essays, burlettas, epistles in Junius' style (for 'Wilkes and liberty'), and the matchless *Balade of Charity*. For a while his prospects seemed golden. The publishers spoke him fair; he obtained an interview with the Lord Mayor Beckford; in the first two months he earned eleven guineas (at the rate of from a farthing to twopence a line); and he sent home glowing letters, with a box of presents for his mother and sister. Then Beckford died; the 'patriotic' publishers took fright; the dead season set in; he had overstocked the market with unpaid wares; a last desperate application failed for the post of surgeon to a Bristol slaver. He was penniless, starving, yet too proud to accept the meal his landlady offered him, when, on 24th August 1770, he locked himself into his garret, tore up his papers, and was found the next morning dead—poisoned with arsenic. They buried him in the paupers' pit of the Shoe Lane Workhouse, a site usurped fifty-six years later by Farringdon Market.

For eighty years the Rowley controversy was waged with no less bitterness than ignorance, the Rowleyans including Jacob Bryant (1781), Dean Milles (1782), and Dr S. R. Matland (1857); the anti-Rowleyans, Tyrwhitt (1777-82) and Warton (1778-82). The subject was once and for ever laid to rest by Professor Skeat in his edition of *Chatterton's Poetical Works* (2 vols. 1875). Vol. i. contains Chatterton's acknowledged poems, 78 in number; vol. ii. the 43 Rowley poems, with an essay thereon by the editor. Almost unconsciously the learned professor establishes Chatterton's wondrous originality. Theft from an unknown poet?—there is not 'the slightest indication that Chatterton had ever seen a MS. of early date.' Indebtedness to Chaucer?—he had 'read very little of this excellent author. . . . If he had really taken pains to read and study Chaucer, or Lydgate, or any old author earlier than the age of Spenser, the Rowley Poems would have been very different. They would then have borne some resemblance to the language of the 15th century, whereas they are rather less like the literature of that period than of any other. . . . The metres are mostly wrong, the rhymes are sometimes faulty; the words [taken mostly from Kersey's Dictionary, and 93 per cent. of them misused] are wrongly coined, or have the wrong number of syllables; and the phrases often involve anachronisms, or, occasionally, plagiarisms.' These last from such recent poets as Dryden and Gray—from the former of whom he boldly stole the line, 'And tears began to flow;' from the latter adapted the conception, 'closed his eyes in endless (everlasting) night.'

'An owl mangling a poor dead nightingale,' said Coleridge of Dean Milles; the words apply to many more critics of Chatterton. There are those among them whose patronising praise and commonplace censure enable us to feel how Chatterton was worsted in life's battle, why he blew up the ship sooner than strike his colours. Others there are—Coleridge, Wordsworth, Shelley, Rossetti—whose precious tributes attest the boy-poet's divinity. No man can tell what Chatterton might have done; what he did do is patent to every one. Had Shakespeare died, or Milton, in his eighteenth year, or even Keats, the world had never heard of their existence. But he, a lad, with chances infinitely less than theirs, had written his name by then so high in Fame's temple, that purblind pilgrims must accept his achievement on hearsay. If he had lived to be famous, the fraud of the 'poet-priest Rowley' would not, belike, have been more hardly blamed than that of 'Jedediah Cleishbotham.' As it is, the conscientious critics have found it less difficult to dilate on Chatterton's pride and scepticism, his vices and deceit, nay, on the meteorology of 1770, than to master the difficult Rowleyan dialect, and to gauge the genius of this nursling of medievalism, this harbinger of the Renaissance of Wonder, to use Mr Theodore Watts's definition of the neo-Romantic movement. For Mr Watts it was reserved to point out Chatterton's metrical inventiveness, and his 'undeniable influence, both as to spirit and as to form, upon the revival in the 19th century of the romantic temper—that temper, without which English poetry can scarcely perhaps hold a place at all when challenged in a court of universal criticism. . . . As a youthful poet showing that power of artistic self-effacement which is generally found to be incompatible with the eager energies of poetic youth—as a producer, that is to say, of work purely artistic and in its highest reaches unadulterated by lyric egotism—the author of the Rowley Poems (if we leave out of consideration the acknowledged poems), however inferior to Keats in point of sheer beauty, stands alongside him in our literature, and stands with him alone.'

See Mr Watts's essay in vol. iii. of Ward's *English Poets* (1880); Sir Herbert Croft's *Love and Madness* (1790); and the *Lives of Chatterton* by Dix (1837), Dr Daniel Wilson (1869), and Professor Masson (1874).

Chaucer, GEOFFREY. The date 1328 for Chaucer's birth is now justly rejected as having no authority and being quite incompatible with some ascertained facts of his later life. There can be little doubt he was born in or about 1340. He was the son of John Chaucer by his second wife Agnes, of unknown surname, a niece of one Hamo de Copton. (His first wife, Joan de Esthale, was certainly living as late as 1331.) This John Chaucer was son of Robert Chaucer, of Ipswich and London, so that the poet's family can be traced to the eastern counties. John Chaucer was a vintner and a tavern-keeper, and may perhaps be identified with the John Chaucer who was deputy to the king's butler in the port of Southampton in 1348, and 'seems afterwards to have held the same situation in the port of London.' John's house was in Thames Street by Walbrook, at or near the foot of Dowgate Hill; and there we may well suppose the future poet was born.

Of his boyhood we know nothing. There were good schools in London then as now—e.g. Paul's Cathedral School and Anthony's, and Chaucer probably was sent to one of them. At a later period the variety and the minuteness of his knowledge are remarkable, and we know that he was an assiduous student. Likely enough his studious habits were more or less formed on the basis of his knowledge laid in his early days. It is possible he may have gone to Oxford or to Cambridge, but there is no evidence of value on this point. In his works he shows some acquaintance with both universities; but this may have been picked up incidentally. What is certain is that in 1357 and 1358 he was a page in the service of Elizabeth, Countess of Ulster, wife of Lionel, Duke of Clarence. From that service he would seem to have been presently transferred to the king's household. In 1359 he first 'bore arms.' He served in the campaign in France in that year—a campaign famous for the bitter sufferings which the English army had to endure. Chaucer was taken prisoner at Retiers in Brittany, but was presently ransomed, the king contributing £16 towards the required amount.

And now we lose sight of Chaucer for some eight years. His father died in 1366, and his mother soon after married one Bartholomew Attechapel; but of Geoffrey no mention has yet been found till 1367, when the king grants him a pension for life, 'or until we shall think it right to make some other order to suit his condition.' He is described as 'dilectus valettus noster' ('our beloved yeoman'), and in an Issue Roll as 'unus valettorum camere regis' ('one of the yeomen of the king's chamber'). It seems fairly certain that by this time Chaucer was married. In 1366 one Philippa Chaucer appears amongst the ladies of the queen's bed-chamber, and there is no good reason for doubting that this was the poet's wife. Her maiden name was in all probability Roet. It is commonly supposed that she was the daughter of Sir Payne Roet of Hainault and king-at-arms of Guienne, and so the sister of Katherine who married Sir Hugh Swinford, and afterwards became the mistress and eventually the wife of John of Gaunt. After the queen's death in 1369 she passed into the household in which her sister was such an important figure, and very likely remained there till her death in 1387. She gave birth, it would seem about 1362 or 1363, to Thomas, a noticeable personage in the House of Commons in the following century; probably to Elizabeth (*circa* 1365), for whose novitiate at the Abbey of Barking John of Gaunt paid some £50 in 1381, and to Lewis, born in the same year in

which his sister was admitted at Barking, for whom his father wrote some ten years later a treatise on the Astrolabe. But the whole matter of Chaucer's married life is involved in much obscurity. It is in evidence that when he was certainly married he speaks of himself several times as one unblest with love's favour; nor can these expressions be explained away as being dramatic and not autobiographical. The picture he draws of himself in the *House of Fame*, a poem undoubtedly written after his marriage, is assuredly that of a forlorn bachelor. On the whole, we believe him to have married about 1360, and that for some reason or other not at present discovered, if ever to be, his married life was disturbed and unhappy.

In the year 1369 Chaucer comes certainly before us as a poet, with his *Death of Blanche the Duchess*. This is not probably his first writing; but it is highly important, because the date of it is exactly fixed by the subject. It laments the death of the Lady Blanche, the first wife of John of Gaunt, which took place in September 1369. It is in many ways a crude composition, and a sufficient proof that Chaucer's art was, like that of many of the greatest masters, not precocious but of slow growth. But even so it illustrates his great gift of style, and gives satisfactory promise of his future excellence.

The following years of Chaucer's life exhibit him to us both as a much-employed man of business and as a rapidly developing man of letters. In 1370 he went abroad on the king's service; in 1372-73 on a royal mission to Italy—to Genoa, Pisa, Florence; in 1376, abroad, it is not known where; in 1377, to Flanders and to France; in 1378, to Italy again. Thus he seems to have been highly valued as a commissioner and a diplomatist. Meanwhile in 1374 he was appointed Comptroller of the Customs and Subsidy of Wools, Skins, and Tanned Hides in the port of London; in 1382, Comptroller of the Petty Customs; and in 1385 he was allowed to nominate a permanent deputy—a most important concession, as by the terms of his appointment he was, like his predecessors, to write the rolls of his office with his own hand and to be continually present. Nor were other marks of royal and of ducal favour wanting. In 1374, on St George's day, the king granted him a pitcher of wine daily, to be received in the port of London from the hands of the king's butler. In the same year John of Gaunt conferred on him a pension of £10 for life for the good service rendered by him and his wife Philippa to the duke, to his consort (the duke's second wife, Constance, daughter of Peter the Cruel, married in 1371), and to his mother the queen. In 1375 he received from the crown the custody of the lands and person of Edmond Staplegate of Kent, which brought him in £104 (well over £1000 of our money), and the custody of some property at Soles, also in Kent. In 1386 he was elected a knight of the shire for Kent. These were Chaucer's most prosperous years in an income-making sense.

To turn to his literary work during these years, the following writings certainly belong to the period between 1369 and 1387—i.e. between the composition of *The Book of the Duchess*, and that of the Prologue to *The Canterbury Tales*—and were probably produced in the order in which they are here named: *The Assembly of Fowls*, *The House of Fame*, *Troilus and Cressida*, and *The Legend of Good Women*; and besides these in unascertained order the Tale of Griselda (afterwards assigned to one of the Canterbury pilgrims—the Clerk), the Tale of Constance (afterwards assigned to the Man of Law), the Legend of the Martyred Christian Boy (afterwards assigned to the Prioress), the Legend of Saint Cecilia (afterwards assigned to the Second Nun), and the Story of Palamon and Arcite in its first shape (afterwards rewritten and assigned to the

Knight). None of these pieces represents the poet's genius in all its fullness or its maturity; they exhibit its gradual expansion and growth. As we see Chaucer in these he is not yet completely master of himself, or wholly satisfied with the instruments at his command—e.g. with the metrical forms then current around him. By far the most important influence acting upon him during this middle period of his literary life was the influence of Italy; and in this respect his going to Genoa in 1372, as already mentioned, had an importance other than commercial or political. That was a journey that made an epoch in his artistic development. It introduced him to poetry in its noblest medieval shape, and in one of the noblest shapes it has ever assumed in any age. Chaucer seems to have felt deeply the greatness of Dante. He appreciated worthily the works of Petrarch and Boccaccio; but to the credit of his judgment, it was Dante that most profoundly impressed him. *The Assembly of Fowls* and *The House of Fame* largely reflect this impression, the latter so closely that Lydgate, as Professor Skeat points out, speaks of it as 'Daunt in English.' Much of his subject-matter he derived from his great Italian contemporaries, especially from Boccaccio. Thus the Reeve's Tale, the Franklin's, and the Shipman's are all to be found in the *Decameron*; *Troilus and Cressida* is to a considerable extent a translation of Boccaccio's *Filostrato*; and the story of Palamon and Arcite is based upon that poet's *Teseide*. The tale of Griselda is taken from a Latin letter of Petrarch's, to whom Chaucer acknowledges his obligation in the Clerk's Prologue. Oddly enough, he never mentions Boccaccio. In one passage in *Troilus and Cressida* he would seem to denote him by the name of Lollius; but certainly in another, when he speaks of 'mine author called Lollius,' he denotes Petrarch, for he proceeds to give a version of one of Petrarch's sonnets. Dante he mentions by name several times. With both Petrarch and Boccaccio it is probable that he was personally acquainted. Boccaccio was living at or near Florence when Chaucer was there in 1372, and Petrarch near Padua, only some 120 miles away. Certainly what is said in the Clerk's Prologue points to an actual meeting with Petrarch.

However this may be, the influence of the Italian poets on Chaucer is beyond question. Nor is it to be measured by what he borrowed in the way of plot or incident or expression. It was far profounder than such debts might suggest. It recreated him as an artist, giving him a new and loftier conception of artistic form and beauty. This regeneration is soon visible in the improvement of his style—in its growing dignity and shapeliness. It is strikingly indicated by his metrical progress. The old four-accented couplet seems to him 'light and lewd'; he needs something weightier and statelier. He does not satisfy this need by importing the favourite Italian metres. The sonnet form does not appear in any extant work of his, though conceivably he may have attempted it. The *terza rima* he does seem to have essayed, as Professor Skeat has been the first to notice; but he did not take to it, or it to him. What he did was to imitate not the letter but the spirit of the Italian masters. And in the heroic heptastich, and presently in the heroic couplet, he found metrical forms that satisfied the highest ideal. The crowning work of the middle period of his life is certainly *Troilus and Cressida*—a work in which the abundant wealth of his genius is lavishly displayed. Probably about the year 1384, when his official duties were so considerably lightened, Chaucer, now a complete master of the poetic craft, began to seek for some great subject; The first selection he made proved unsatisfactory;

it was the *Legend of Good Women*. The Prologue to this famous fragment is an admirable piece of writing; but the theme was soon felt to be wearisomely monotonous, and was abandoned. His second choice was happier, as it provided full scope for his various powers—for his humour and his dramatic faculty, as well as for his pathos and more purely poetical gift. This was the *Canterbury Pilgrimage*.

But before that final choice was made, having been suggested probably by an actual journey to St Thomas's shrine, some strange reverses of fortune had befallen Chaucer. About the close of the year 1386 he was deprived of both his places in the civil service; and from this time to very nearly the end of his life, with slight intermissions, things went ill with him. The cause of his dismissal is obscure; possibly he was involved in the intrigues that disturbed and disordered the court in the reign of King Richard II.; possibly also there was some genuine dissatisfaction with the way in which his official work had been or was being performed. In 1389 he received a new appointment—he was appointed Clerk of the King's Works at the palace of Westminster, Tower of London, castle of Berkhamstead, the king's manors of Kennington, Eltham, Clarendon, Sheen, Byfleet, Langley, and Feckenham, and elsewhere, in this case, too, being allowed to nominate a deputy; but his previous fate seems to have pursued him. Two years afterwards we find him superseded by one John Gedney. It was during this term of office that he went through the odd experience of being robbed twice in one day. What glimpses we have of him in the succeeding years show him in perpetual impecuniosity and distress. It seems fairly clear that thrift was not one of his virtues. No sort of provision seems to have been made against a 'rainy day'; and now came many rainy days. For some two years he had to subsist as best he might on John of Gaunt's pension of £10, his salary as one of the foresters of North Petherton Park, Somersetshire, and whatever wages, if any, were paid him as a king's esquire. In 1394 King Richard granted him a pension of £20 for life; but the advances of payment he applies for in the following year, and again and again later on, and other signs, such as the issue on his behalf of letters of protection from arrest for debt, sufficiently indicate his unprosperous condition. An improvement came with the accession to the throne of the son of his old friend and patron John of Gaunt. In October 1399, King Henry IV. granted him a pension of 40 marks (£26, 13s. 4d.). This would raise his income to at least £500 a year of our money. And we may believe his few remaining months were spent in comfort. The following Christmas he took a lease for 53 years, at an annual rent of £2, 13s. 4d., of a house situated in the garden of the Lady Chapel, Westminster, the site now of what is commonly known as Henry VII.'s Chapel. But the end was near. Our last trace of him is the payment of a pension instalment in June 1400, made not to him personally, but to one Henry Somers in his behalf. Before the close of the century, of which he was in England the supreme literary glory, he was laid in that part of the abbey which through his burial there came afterwards to be called the Poet's Corner. His tombstone says he died October 25, 1400; and though the present tomb dates only from the 16th century, it probably perpetuates some older inscription.

In spite of all his reverses and troubles, it was during this last period of his life that Chaucer's genius shone brightest.

A merry heart goes all the day;
Your sad tires in a mile-a.

Having formed a design that permitted the full

expression of his abundant and many-sided genius, he vigorously pursued it amidst the darkness that overclouded him. The design was indeed too huge for completion; and no doubt for all his vigour and buoyancy his troubles interfered with his progress. Moreover he was approaching or had reached what amidst the unhealthy ways and conditions of mediæval life was accounted old age. Hence his work remains but a fragment; but it is a fragment of large and splendid dimensions, consisting of parts that are admirably finished wholes, each one of which illustrates some special feature of the poet's versatile mind and art, and justifies and insures his fame. His greatest achievement is the Prologue to the *Canterbury Tales*, which for its variety, humour, grace, reality, and comprehensiveness is, as a piece of descriptive writing, unique in English literature—unique in all literature indeed. It portrays for us the society of the later middle ages in unfading colours, and historically as well as artistically is of inestimable excellence and value. Chaucer is in order of time the first great poet of the English race, if the term English may be used as distinguished from Anglo-Saxon; and in order of merit he is amongst the first of all our poets. It might indeed be disputed whether he does not deserve the place next to Shakespeare. In the middle ages in England he stands supreme, with neither equal nor second.

See Tyrwhitt's *Introductory Discourse to the Canterbury Tales* (1775-78); Nicolas' *Life of Chaucer* in the Aldine Edition; Bernard Ten Brink's *Chaucer-Studien* (vol. i. 1870); the Chaucer volumes in the Clarendon Press series; and Professor Child's *Observations on the Language of Chaucer and Gower*, of which distinguished work a full account is given, with much other important matter, by Mr A. J. Ellis in the fourth chapter of his *Early English Pronunciation*. As to Chaucer's language and the dialect to which it belongs—viz. the East Midland variety of middle English, much help will be found in the Clarendon Press volumes of Dr Morris and of Professor Skeat; editions of the Prologue and three of the tales, issued by W. & R. Chambers; Sweet's *Middle English Primers*; and in Ten Brink's *Chaucer's Sprache und Verskunst* (1884). Invaluable to the Chaucer student is Dr Furnivall's Six-text Print of the *Canterbury Tales*, and the other issues of the Chaucer Society. A Concordance is being prepared by members of the same society. It must be noted that many works have been ascribed to Chaucer, and are still printed in popular editions, that are certainly not his—e.g. *The Court of Love*, *Chaucer's Dream*, *The Complaint of the Black Knight*, *The Cuckoo and Nightingale*, *The Flower and the Leaf*, and in all probability the extant *Romaunt of the Rose*.

For criticism of the poetry, see Ward's *Chaucer* in the 'English Men of Letters' series; Morley's *English Writers* (vol. iv. in new ed.); Warton's *History of English Poetry*; and a fine essay by J. R. Lowell in *My Study Windows*.

Chaudes-Aigues, a town in the French department of Cantal, 90 miles S. of Clermont, with four mineral springs, which vary in temperature from 135° to 177° F. They have the property of discharging grease from sheep's wool, and vast numbers of fleeces are sent hither annually to be washed. The waters are also useful in rheumatism and cutaneous diseases. Pop. 1182.

Chaudfontaine, a Belgian village charmingly situated in the valley of the Vesdre, 5 miles SSE. of Liège by rail, with mineral springs (92° F.). Pop. 1532.

Chaudière, a river and lake of Canada. The river joins the St Lawrence from the south 7 miles above Quebec, and, 2½ miles from its mouth, forms the celebrated falls of Chaudière. The lake—merely one of the many expansions of the Ottawa—has on its right the city of that name, the capital of the Dominion.

Chaumette, PIERRE GASPARD, one of the French Revolutionists, was born a shoemaker's son

at Nevers in 1793. He was some years a seaman, but the opening of the Revolution found him a clerk at Paris. He attached himself to Camille Desmoulins, and soon gained such popularity by his extravagant anacolutism that he was appointed procurator of the commune of Paris. In his zeal he rejected his own Christian name, Pierre, as having been sullied by saintly associations, and styled himself 'Anaxagoras.' The institution of the tribunal of the Revolution, the decree for a revolutionary army, and the law against suspected aristocrats, were largely due to his efforts. One of his proposals was that all Parisians should wear sabots, another that the Tuileries and Luxembourg gardens should be planted with potatoes. His antics in connection with the 'worship of reason' excited the disgust of Robespierre, who devised measures for bringing the whole company of actors under Hébert to the scaffold. He was executed April 13, 1794.

Chaumont, a town in the French department of Haute-Marne, on an elevation (1023 feet above sea-level) between the rivers Marne and Sûze, 140 miles SE. of Paris. There are manufactures of gloves, cutlery, &c. In 1814 the allied powers here bound themselves by treaty against Napoleon. Pop. (1872) 8474; (1886) 12,333.

Chauny, a town in the French department of Aisne, 77 miles NNE. of Paris by rail, partly on the navigable river Oise. It is an old, rather uninteresting place, with manufactures of glass, beetroot sugar, gloves, &c. Pop. 8847.

Chausses, in the armour of the middle ages, from the 12th to the 16th century, were defence-pieces for the legs. Some were made of padded and quilted cloth, with metal studs; some of chain-mail; and some of riveted plates. It was not unusual to fasten them by lacing either below the knee or behind the leg. The word is used also in the general sense of hose, and when armour is meant in the Norman romances the phrase is *chausses de fer*.

Chautauqua, a celebrated summer-resort on Chautauqua Lake, in a county of the same name near the south-west extremity of the state of New York, is famous as the seat of the 'Chautauqua Assembly,' founded in 1874 by John H. Vincent, D.D., and Lewis Miller, to provide systematic instruction for Sunday-school teachers, together with popular lecture courses in literature, science, and art. In 1878 the Chautauqua Literary and Scientific Circle was organised. The distinctive mission of this 'circle' is stated to be 'to direct the reading habits of grown people, both those who have received the best that the educational institutions can give, and desire to pursue an "after school" course, and those who for any reason failed to receive a college education in early life, but who now desire to secure to themselves the college student's general outlook upon the world and life, and to develop the habit of close connected persistent thinking.' The system comprehends a four years' course of home reading and study, to be pursued under the advisory supervision of the officers of the institution, on the completion of which diplomas are awarded. Post-graduate and special courses are also provided for those who desire to prosecute particular branches of study beyond the limits laid down in the regular course. On the tenth anniversary of the Circle's organisation, it was stated that about 200,000 persons, scattered through all parts of the world, belonged to the association; most of them are members of local circles formed in accordance with the general plan of the scheme for the more efficient prosecution of the studies. Particulars concerning the

Chautauqua Literary and Scientific Circle, with directions for forming local circles in connection therewith, may be obtained from the secretary of the institution at Plainfield, New Jersey. 'The Chautauqua College of Liberal Arts' is another department of the work. A faculty of able professors gives instruction by correspondence, and after rigid examinations the regular collegiate degrees are conferred under charter from the state of New York. *The Chautauquan*, a magazine of large circulation, the organ and exponent of 'The Chautauqua Idea,' is published at Meadville, Pa. See F. L. Armstrong's *Chautauqua* (Brattleboro, 1886).

Lake Chautauqua is a beautiful sheet of water about 20 miles long, with an average breadth of 2 miles, lying about 700 feet above Lake Erie, from which it is distant 10 miles. The Chautauqua Assembly Grounds, situated upon the northern shore of the lake, comprise about 165 acres, containing over 500 attractive summer cottages, a fine hotel, a museum of archaeology, an amphitheatre with a seating capacity of over 5000, several halls for meetings, and numerous other appliances for combining recreation with instruction. Large numbers of students and visitors congregate here in the summer season. 'Chatauquas,' more or less on the plan of the original, with buildings, lectures, &c., have been established in various parts of the United States.

Chauvinisme, a term that has come to mean an extravagant and absurd patriotism and pride in one's own country, with a corresponding enmity towards and contempt for foreign nations. It is the French equivalent for the *Jingoism* of the London music-halls after Lord Beaconsfield's return from the Congress of Berlin in 1878. The origin of the word is due to Chauvin, the name of a figure in the comedy *La Cocarde tricolore* (1831), by the brothers Théodore and Hippolyte Cognard, the action in which includes the conquest of Algeria. Chauvin is a young recruit who speaks much, displays great courage, and sings several couplets with the refrain: 'J'suis Français, j'suis Chauvin, j'tape sur le Bédouin.' The authors of the comedy, however, borrowed the name from that of Nicolas Chauvin, an old soldier of Napoleon, well known in his time in Paris for his devoted enthusiasm for the emperor. *Calvin* is a Latinised form of the same family name.

Chaux de Fonds, a town of Switzerland, in the canton of Neuchâtel, 18 miles by rail NW. of the city of that name. It is situated in a bleak valley, at an elevation of 3254 feet above the sea, and is scattered over a large area, almost every cottage being surrounded by a garden. It has for two centuries been one of the chief seats of the manufacture of watches in the canton. The mechanists work chiefly at home, each devoting himself to a particular portion of machinery. Pop. (1834) 6500; (1880) 22,456.

Chay Root, CHOYA, or SAYAN (*Oldenlandia umbellata*), a perennial herb of the order Cinchonaceæ, cultivated on the Coromandel coast and in Java for the sake of its long, orange-coloured roots, the bark of which affords a beautiful red dye. It is the Indian madder.

Chazars were a people of the Finnic stock known in the 7th century on the shores of the Caspian; in the 9th century their kingdom occupied the south-east of Russia from the Caspian and the Volga to the Dnieper. Their capital was long at Astrakhan, called by them Balandshar. They were singularly tolerant of all religions, Jewish, Christian, and Moslem; and a large part of the nation formally adopted the Jewish faith from Jews who fled from the persecutions of the

Emperor Leo. Cyril converted many to Christianity in the 9th century. The power of the Chazars was ultimately broken in the 12th century by the Byzantine emperors and the Russians.

Chazy Epoch, the name given by American geologists to that division of Silurian time during which the Chazy limestone of New York, Canada, &c. was formed.

Cheadle, a market-town in the moorland district of Staffordshire, 14 miles NNE. of Stafford. Lying in a pleasant vale, engirt by wooded hills, it has a parish church, rebuilt in 1837-38, and a Roman Catholic Church, erected in 1846 from designs by Pugin, at a cost of £60,000. Pop. of parish (1881) 4724.

Cheating. In the technical language of the English law, cheating means the offence of fraudulently obtaining the property of another by any deceitful or illegal practice short of felony, but in such a way that the public interest may possibly be affected. In order to constitute cheating, the fraud must be of such a kind that it could not be guarded against by common prudence. Cheating, in this sense, is an offence at common law, and indictable, which is not the case with imposition in a private transaction. The law of Scotland has no such distinction. The following are instances of cheating: Selling by a false weight or measure (which is also a statutory offence under the Weights and Measures Act, 1878); selling unwholesome bread as if it were wholesome. Cheating seems, therefore, to be distinguished from obtaining property or credit on false pretences by the absence of any definite false statement. Cheating is also technically used in connection with frauds at play with cards or dice, but is popularly applied to almost every form of fraud. In Scots law, cheating is generally prosecuted under the name of falsehood, fraud, and wilful imposition, and has by one authority been called practical cheating, as distinguished from those cases in which a spoken or written false pretence occurs. See FRAUD, FALSE PRETENCES.

Checkerberry. See WINTERGREEN.

Chequy, or CHECKY, in Heraldry, a term applied to a field or charge divided into small

Chequy.

Fess Chequy.

squares by transverse perpendicular and horizontal lines. Chequy or and azure is the coat of Vermandois in France, and of Warren, Earl of Surrey, in England. The well-known coat of the Scottish family of Stewart, or, a fess chequy azure and argent, is allusive to the checkers of the Stewart's board, by which money computations were in old times made.

Cheddar, a village in Somersetshire, on the south side of the Mendip Hills, 21½ miles SSW. of Bristol by rail. It lies at the entrance of a deep rocky gorge, nearly 1 mile long, whose stupendous limestone cliffs contain caverns—one 300 feet long—filled with fantastic stalactites and stalagmites. For the famous Cheddar cheese, originally made here, see CHEESE. Pop. of parish (1881) 2366.

Chedu'ba (or *Man-aung*), a well-wooded island of Arakan, in the Bay of Bengal, with an area of 240 sq. m., and a pop. (1881) of 23,867. The soil is fertile, rice and tobacco being the chief crops; and petroleum is found in several localities.

Cheese is a highly nutritious food substance made from milk by elaborate processes which can

only be explained in the light of a knowledge of science, chiefly chemistry. Cheeses may be roughly divided into two great classes—*hard* and *soft*. The various English, Scotch, and American cheeses belong to the first class, and are made so that they will generally keep for months, and often continue to improve in quality. Soft cheeses are those which prevail in some parts of the Continent. Many of them require to be consumed immediately after they are manufactured. Their rapid decomposition is associated with a strong and to most people an objectionable smell. Cheese is made from the solids of milk—viz. the casein or chief albuminoid constituent, along with the greater part of the cream or butter-fat, and much of the mineral ash. In fresh milk, which is slightly alkaline, these substances maintain a sort of indescribable union with the watery portion and the milk-sugar—the whole, as is well known, being liquid. The presence of an acid, or of Rennet (q.v.), counteracts the natural affinity of the substances for each other, and the bulk of the solids separate out, forming a soft jelly in the early stages, leaving the bulk of the water containing the sugar as a greenish liquid called Whey (q.v.). The chemical processes involved are as yet only very imperfectly understood.

Milk in decomposing, as it rapidly does in hot and sultry weather, becomes sour in virtue of a natural process of fermentation. Rennet induces another form of fermentation which does not end when the product ceases to be milk, but is carried on in the cheese during the period of its ripening or mellowing. In the early stages of the process of hard cheese-making, the incipient acidity which induces that condition in milk termed 'ripeness,' aids and hastens the action of the rennet. As the work proceeds, and the acidity intensifies, it hardens and contracts the curd, giving it a leathery character, thereby aiding in the expulsion of the whey. One of the most important matters in cheese-making is to watch the development of acidity both in the milk and its first product, the curd. If this is allowed to go too far, the quality of the cheese is seriously injured, and its keeping power is reduced. It cracks through becoming too dry and brittle. The delicate flavouring oils seem to be expelled, and the smell becomes high and the taste 'acid' or 'biting.' The formation of the acid is one of the great helps in cheese-making so long as it is kept in due control. If the acid develops rapidly, as in hot weather, in a temperature which suits the germs producing it, the whole process of manufacture has to be pushed on quickly, whereas in cold weather acidity comes slowly, and the operator must wait until it has come sufficiently. There are several methods adopted in inducing acidity. Acid used to be largely added, as sour whey or buttermilk, but greater uniformity is got by delaying until natural acidity develops. This it does most quickly when the temperature of the material is kept up near to blood-heat. Chilly draughts paralyse the active organisms producing acidity.

Heat is communicated to milk or to its products in the early stages of cheese-making by two methods—either by warming a portion of the milk or whey (though not allowing it to rise much above 100° F.—say a limit of 150° F.—as to boil it would do injury by changing its constitution), and putting it into the main bulk, or by having an outer shell of wood to the tin or iron cheese-tub, with a space between into which steam or hot water can be injected. This arrangement possesses the additional advantage of being clean and of saving labour, although the cost of the apparatus is greater. When the temperature of the evening's milk requires to be reduced to insure its keeping overnight, as in hot weather, cold water can be

employed in the same manner as hot water or steam.

It would be misleading to fix definite temperatures or assume definite rules of any kind in speaking of the broad principles and practices of British cheese-making, because there are so many systems which differ materially in important particulars.

A thermometer should be used at all times and in all systems. The old method of testing by the hand hardly now exists, and certainly not among good cheesemakers. The ordinary temperatures at which milk is set or steeped vary with the system adopted and the temperature of the atmosphere—from 80° to 90°, more or less, is the nearest indication that it is safe to make. High temperatures are used in making *deep* cheeses, such as Cheddars; low temperatures in making *shallow* cheeses, as the old-fashioned Dunlops. The Gloucester is a well-known variety set at a temperature nearer to 80° than 90° F. By setting at too high a temperature the curd gets hard and tough, though it needs a considerable amount of consistency if it is to retain a symmetrical form in a deep cheese. If worked too cold, the curd is soft and the whey difficult to get out of it, the processes of rennet fermentation and acid fermentation do not go on sufficiently, and their work is imperfect. In all cases the greatest regularity in method should be maintained from day to day.

After heating, the colouring matter (now almost invariably Annatto, q.v.) is put in. This is not considered an adulteration, as it is innocuous. It in no way improves the quality of the cheese, the effect being only upon the colour. All cheeses are not coloured, though the practice is widespread. Rennet is put in about the same time, and after thorough stirring for the purpose of mixing these added ingredients, as well as for keeping down the cream, it is left for 40 or 60 minutes.

Breaking the curd to let out the whey is the next process. Networks of thin wire, or series of thin knives, are passed through it in various directions with great caution, to prevent the curd substance being carried off with the whey, which would give it a white rather than its natural green hue. As the curd hardens it is more quickly worked and finally broken into small particles, so as to allow the whey to escape. The expulsion of the latter is helped on by the contraction of the curd, due to the gradual increase of acidity. Acidity develops naturally if time is allowed, but it is judicious to hasten it by the addition of warm whey during the process of working. Another method of bringing about the necessary amount of acidity is to expose the curd to the air for a time before it is salted. Salt, besides giving a flavour, stops the action of the acidity in cheese after it has done its work of expelling the whey. If allowed to go on, the acidity would destroy the cheese by curtailing the ripening action of rennet. Excess of salt retards the latter process.

After the curd has been broken thoroughly, on being allowed to settle so as to drain off the whey, it adheres together into an india-rubber-like mass; this is cut and broken up into small pieces by its passage through a 'curd-mill.' The finest quality of dairy salt should be used; the crystals being large is an indication of its purity, especially from magnesia salts, which give a bitter taste and otherwise injure all dairy products. The quantity employed is, more or less, about 1 lb. of salt to 56 lb. of curd dry enough to be made up and put into the cheese-press. Its amount should vary with the degree of acidity and the amount of moisture present. In some cases salt is applied wholly or in part dry, or as a brine, to the outside of the cheese after it has been so far pressed. In very rare cases salt is put into the milk before coagulation.

The curd is finally packed into a 'chesset' or press vat, which has as a temporary lining a cloth of open texture called a 'cheese-cloth.' The vat, which is a strong wooden or tinned-iron vessel with perforations in the sides and bottom to allow of the escape of any little surplus moisture, is placed in a press, and the cheese subjected gradually to a pressure of about one ton. The curd soon assumes the form in which it is to remain as a cheese. For a few days the cloths are taken off regularly and changed; the cheese being turned over each time to make it keep its shape. Ripening is the next process of importance. Deep cheeses are bandaged, and some are covered with cotton cloths (caps) made to fit tightly. They are then placed in the curing or ripening room, which should be dry, well ventilated, and maintained at an even temperature of about 70° F. There the green indigestible and insipid curd changes naturally into the sweet, mellow, nutty, and full-flavoured product cheese, which, if taken in moderation, and especially towards the end of a meal, is an aid to digestion. The ripening process, which is also associated with drying and shrinkage of about 10 per cent. in weight, varies in length from a few weeks to a few months. Acid cheeses are soon ready for market, and spoil if kept for a long time. Sweet cheeses are slow in maturing, and continue to improve even if kept for years. The tendency in cheese-making both in Great Britain and in America has recently been to early maturity, the strong inducement being that of early returns.

The Cheddar system of cheese-making, which first originated in Somersetshire, is, if we embrace Great Britain, Canada, and the United States of America, the most widely practised system of all. The old methods have been much altered in recent times to suit the tendency in the market for early maturity. The following is an account of the system as now practised, with improvements suggested by American and Canadian experience.

The cream is removed from the evening's milk after standing overnight, and is only returned to the full bulk immediately before putting in the rennet; the object is to prevent the cream being made oily by heating to a high temperature. The rennet is added at a temperature ranging from 82° to 88° F., but the milk is heated a few degrees above the point fixed upon for steeping, and left to ripen. The temperature falls to the required point meanwhile. The higher range of temperature is adopted when the milk is sweet and recently drawn from the cow. Low temperatures suit old milk or warm weather. If the cheese is to be marketed within twenty days, enough rennet should be added to induce the initial stages of coagulation within eight to twelve minutes. After this it should be left for twelve to eighteen minutes, then breaking begins with the perpendicular and horizontal cutting knives. It is stirred for about fifteen minutes with a hand-rake, and the temperature afterwards raised to 96°-98° F., or even by some up to 102° F. The whole is allowed to settle and remain nearly an hour to 'cook' the curd. As soon as the latter is elastic enough for the particles to retain their independent shapes on being grasped and squeezed by hand, the bulk of the whey is run off. What remains and the curd, still in small pieces, are removed bodily from the steep-tub or vat, and placed in a flat cooler with an inner movable, sparged, false bottom, to secure drainage. The vessel is lined with a cheese-cloth. On this the curd is exposed to the air and well worked by hand, so as to press out the whey and keep the particles from adhering to one another at too early a stage. After being well worked and exposed it is left to run together, being covered up

to preserve heat. It is subsequently cut, piled, and left covered with a cloth for perhaps half an hour. The curd then smells and tastes slightly acid. It is either milled or put through Harris's stamp lever breaker, which cuts it into pieces like fingers. It is subsequently weighed, and should amount to fully 1 lb. to the gallon of milk, and is again exposed to the air to get quit of taints, and to toughen before salting, which should be done when a velvety feeling is noticeable. The salt is added dry at three separate times, and well mixed. The curd is then left to cool down to about 70° F. before being put into the vat. Pressure for about two and a half days is followed by ripening or seasoning. The whole operation of making up the curd may be over in five hours, or may take six or seven hours, according to circumstances. A good Cheddar cheese contains when ripe about 28 per cent. of casein, and nearly 34 per cent. both of butter and of moisture.

Cheshire Cheeses are manufactured in Cheshire, Staffordshire, and Shropshire. In their deep shape and also in many details of their working they resemble Cheddars. Setting is done in a square covered vat, and after making up they are often put into an oven to cook for a night before going to press. In the latter they remain for nearly a week. *Derbyshire Cheeses* are steeped and worked in a manner which closely corresponds to the Cheshire system. The salt, however, is applied externally. *Gloucester Cheeses* are made by a sweet process very much the same as the Derbyshire process. *Double and Single Gloucesters* are identical, with the exception of the thickness and the consequent rate at which they ripen. After a time they are scraped clean and painted with Spanish brown. *Leicester Cheeses* are small and flat, and made by a sweet process. They are at first lightly salted, but salt continues to be added externally. They take a long time to mature.

Stilton Cheeses are made mostly in Leicester. They used to be double cream cheeses, but are now successfully made of the milk as it comes from the cow. The curd is not subjected to pressure like that used in making the previously mentioned forms. While on the shelves ripening it is supported by a bandage, and during that time the characteristic blue mould should form throughout its substance.

Gruyère Cheese, made in the canton of Fribourg, Switzerland, is a whole-milk cheese, as are also the Dutch cheeses of *Gouda* and *Edam*. The fancy cheeses of the Continent, as *Camembert*, *Brie*, *Roquefort*, *Limburg*, *Gorgonzola*, &c., command a high retail price in Britain because of their perishable nature and because their consumption is restricted to a limited and wealthy class. Imitations have been made, but of a spurious and imperfect kind, owing to the impossibility of securing the secrets of their manufacture. The broad facts are known, but not the details. For example, it is quite understood that some soft cheeses are made by mixing old and new curd together. The quality of the natural pastures also affects some, notably the *Parmesan* cheeses from northern Italy. See the works on dairying named at BUTTER; and Harris's *Cheese and Butter Maker's Handbook* (1885).

AMERICAN CHEESE AND CHEESE-MAKING.—The art of cheese-making in America has undergone a radical change. Previous to the introduction of the factory system American cheese was pungent in flavour and decomposed rapidly. Consequently American cheese was not popular in foreign markets, and met with a very restricted sale. Since the factory system has been brought to a high condition of excellence, American cheese competes favourably, in even the English market, with the home-

made Cheddar, Cheshire, and other popular kinds. The system practised in American factories is an improved Cheddar process, and prominent English experts have at times referred to the American system as being worthy of imitation in English dairies. Under the prevailing system the manufacture of cheese in America (the United States and Canada) increased more than 100 per cent., as the following figures will show:

	United States.	Canada.
Product of Cheese—

Since 1880 up to 1888 the manufacture and export of cheese from the United States has fallen off, but that from Canada has increased. The decrease in exports from the United States has been due to the too prevalent adulteration of cheese with oleo-margarine and lard oils, through which the quality has fallen off and an unfavourable reputation has been acquired, while Canadian cheese has been kept pure. In 1879 Canadian cheese carried off the Sweepstakes prize at the International Exhibition held in New York against the competition of both United States and English cheese. Since 1880 Canadian cheese of the best autumn makes has sold in England for more than the average English Cheddar.

The American system of cheese-making has been reduced by improved mechanism and association in the form of the factory method to the most economical point. This method of manufacture was a growth by necessity rather than a discovery. A large dairy was divided by the death of the owner, who left three sons. The sons united and manufactured their milk at the old dairy, and in time neighbours joined, and the first factory was established in 1851 under the management of the oldest of the three brothers. In course of time the business increased and became reduced to a most economical basis, while by the employment of skilful operatives the quality of the product was gradually raised. The factories were gradually enlarged until the milk of 1200 cows could be worked up in the largest, and an average factory received the milk of about 400 cows. One Canadian factory makes 216,000 lb. of cheese yearly from the milk of 1300 cows.

The curing occupies about three months, the temperature of the curing-room being kept at 65° F. Gang presses are used, in which a large number of cheeses laid on their sides are pressed at once by turning one screw. A common test by which the ripeness of the curd for pressure is determined is by touching it with a hot iron, and when long strings are drawn from the curd by the iron, the curd is ripe.

Milk is brought to the factory twice daily, and is weighed and run into the vat from the delivery window. The milk is either bought by the factory, or is worked up at a stated charge, or the factory is managed on the co-operative plan in which the net proceeds are divided periodically. Under this factory system the quality of the cheese is uniform and as high as is secured in any well-managed private dairy. About one-fifth of the cheese pro-

Success in America is made in private dairies in which the same system prevails.

There are several other kinds of cheese made in both factories and private dairies, as Edam (the round Dutch cheese), a small cylindrical cheese similar to the English Wiltshire, weighing 10 to 14 lb.; a flat cheese called English dairy cheese, similar to the double Gloucester cheese and coloured as highly; a few Stilton cheese; cream cheeses for immediate use; and very good imitations of the European Limburger, Schweizer, Neufchatel, Brié, Gouda, Camembert; and some other fancy makes to supply the French, German, and other immigrant population.

The cows used in the cheese dairies in the United States and Canada are mostly 'grade' shorthorns, or native cows improved by crosses of shorthorn, Devon, Ayrshire, and Dutch breeds. Jersey and Guernsey cows, and the best of the higher bred animals, are used for the highest class of cheese of the fancy kinds. The profitable exploitation of the dairy in America has raised the value of lands suitable for grazing cows to an average value of nearly \$100 (£20) per acre for the fee simple, which is twice as much as that of grain farms. The cheese-dairy business prevails mostly in the states of New York, Pennsylvania, Ohio, Iowa, and Wisconsin, and in the province of Ontario, Canada. The cows are chiefly fed upon pasturage aided in the latter part of the summer by soiling crops, of which maize is almost universally chiefly depended upon. The cheese-making season begins in April and continues until November. See K. A. Willard's *Practical Dairy Husbandry* (1875), L. B. Arnold's *American Dairying* (1877), and Henry Stewart's *American Dairyman's Manual*.

CHEESE-PRESS.—The most common form is the lever press. A powerful steel coil or spring is sometimes substituted for the lever. In large factories the gang press is employed to press a large number of cheeses at one time by means of a powerful horizontal screw. The old method was by placing a heavy stone (hence the name stoning cheese) on the lid of the chesset, or by hanging it by a ring fixed to its upper side from the end of a wooden beam which acted as a lever and passed over the lid of the cheese-press vat.

Cheese-hopper, the larva of *Piophilid casci*, a small dipterous (two-winged) fly, of the large family Muscidae, to which the house-fly, blow-fly, &c. belong. The perfect insect is about a line and a half in length, mostly of a shining black colour; antennae, forehead, and some parts of the legs reddish. It is a pest of dairies and store-closets, laying its eggs in cracks or crevices of cheese, the destined food of its numerous, active, and voracious larvae. To preserve cheeses from this pest, it is of advantage to brush or rub them frequently, and to

Cheese-hopper :

a, larva, natural size; b, larva, magnified, preparing to spring; c, perfect insect, natural size; d, magnified.

remove all cracked or injured cheeses from large stores, besides keeping them dry and in a well-aired place. The same rules are applicable in regard to the other insect larvae by which cheeses are some-

times infested. Of these the most notable are the larvae of the Bacon Beetle (see *DERMESTES*), and of another species of dipterous fly, *Musca corvina*.

Cheese-mite (*Tyroglyphus siro*), familiar on old dry cheese. It is a true Mite, and belongs to the division without special breathing organs. The body is rounded behind, conical in front, with a well-marked groove between the second and third pairs of legs, and with relatively long smooth hairs. The male differs slightly from the female, for instance in the possession of two posterior suctorial pits. The larvae have only three pairs of legs, and pass through an immature eight-legged 'nymph' stage before becoming like the adults. The cheese-mite is not confined to cheese, but attacks dried fruits and the like. See *ACARINA* (with cut), *ARACHNIDA*, *MITE*; also Michael, *Journ. Roy. Microscop. Soc.* 1884, 1885.

Cheetah, or **HUNTING LEOPARD** (*Felis jubata* or *Cynailurus jubatus*), an animal of the feline family, distinguished by its longer and narrower

Cheetah.

feet and less completely retractile claws, which are also more blunt and less curved. It also differs from other Felidae in certain dental characters—e.g. of the upper sectorial tooth. With these peculiarities are associated a greater length of limb than is usual in feline animals, and the habit of taking its prey by running rather than by leaping. The cheetah is in size about equal to a leopard, but the body and limbs are longer. The colour is yellowish brown, with black and brown spots. It is very widely distributed, being found in Senegal, South Africa, Persia, India, Sumatra, &c. Its geographic range extends from the Cape of Good Hope as far north as the Caspian Sea and the steppes of the Kirghiz Tartars. The African form is sometimes distinguished as *C. guttatus*, but the differences are trivial. The animal has been long domesticated and employed in the chase, both in Persia, where it is called *Youze*, and in India. Deer and antelopes are the game principally hunted, and packs of cheetah are kept for this purpose by Indian princes. The head of the cheetah is kept covered with a leather hood till within 200 yards of the game. When the hood is taken off, the cheetah stealthily creeps towards the herd, taking advantage of every bush and inequality for concealment, till, on their showing alarm, he is amongst them at a few bounds, and striking down his victim with a blow of his paw, instantly tears open its throat, and begins to suck the blood. It is then somewhat difficult to withdraw him from his prey, which is generally done by offering him meat. If unsuccessful, the cheetah does not attempt to follow the herd by running—nor does this animal seem to possess the power of maintaining speed through a lengthened chase, but slowly, and as if ashamed, creeps back to the hunters. In a domesticated state it is

extremely fond of attention, and seems to repay kindness with affection.

Cheever, GEORGE BARRELL, American clergyman, born in Maine in 1807, was educated at Bowdoin College and Andover Theological Seminary, and from 1832 to 1870 was pastor of Congregational and Presbyterian churches in Salem (Massachusetts) and New York. He delivered numerous lectures on religious, literary, and social questions, and published a number of works, the most popular of which is his *Lectures on the Pilgrim's Progress* (1844), which, with his *Wanderings of a Pilgrim in the Shadow of Mont Blanc* (1845-46), has had a wide circulation in England as well as in America. In his prime Dr Cheever was an active and uncompromising opponent of intemperance and slavery.

Che-foo (properly the name of the European colony of the Chinese town of *Yen-Tai*), a treaty port on the north side of the peninsula of Shan-tung, at the entrance to the Gulf of Pechili, in which it is the only port that remains open throughout the winter. The foreign quarter, with about 120 Europeans and Americans, is in some sense a colony of Shanghai, and, having the wholesomest climate of all the treaty ports, it is much resorted to by convalescents. The Chinese town, built on the sandy shore, with exceedingly dirty streets, has a fort, a signal-station, and about 32,000 inhabitants. As a market for foreign manufactured goods, particularly English cotton yarn and American sheetings, Che-foo is of great and increasing importance. In 1887 the value of imports was £1,760,967, of which £1,145,749 were foreign goods; of exports, £1,347,427. The principal articles of import besides those mentioned are sugar, paper, iron, edible seaweed, matches, and opium. The chief exports are silk, straw-braid, bean-cake, and vermicelli. The total number of vessels entered and cleared during 1887 was 2081, of 1,656,075 tons, of which 1130, of 958,821 tons, were British. The *Che-foo Convention*, which settled several disputed points between China and Great Britain, and extended certain commercial advantages to the latter country, besides throwing open four new treaty ports, was signed 13th September 1876.

Cheiranthus. See WALLFLOWER.

Cheirolepis, a genus of fossil ganoid fishes, characteristic of the Devonian strata. The generic name, meaning 'scaly-hand', was given in allusion to the large pectoral scaly fins.

Cheiomys. See AYE-AYE.

Cheironectes, an aberrant genus of Opossums (q.v.), with webbed hind-feet and of unique aquatic habit. There is but one species, *C. variegatus*, *palmatus*, or Yapock (q.v.).

Cheiroptera ('wing-handed'), the technical name for the order of Bats (q.v.).

Cheirotherium (Gr., 'hand-beast'), the name originally given to the Labyrinthodont (q.v.), from the peculiar hand-like impressions left by it in the Triassic rocks.

Cheke, SIR JOHN, one of the revivers of Greek learning in England, was born in 1514 at Cambridge, and in 1529 obtained a fellowship of St John's College, where he embraced the Reformed doctrines. He laboured earnestly to advance the study of the Greek language and literature; and when a regius professorship of Greek was founded at Cambridge in 1540, Cheke was appointed its first occupant. A new mode of pronouncing Greek which he introduced was assailed by Bishop Gardiner, the chancellor of the university; but notwithstanding, Cheke's system prevailed. It resembled that still in vogue in England, as opposed to the continental system. In 1544 Cheke

became tutor to the Prince, afterwards Edward VI., whose elevation to the throne secured him rank, wealth, and honour—a seat in parliament (1542), the provostship of King's College (1548), and knighthood (1552). He was stripped of everything at Mary's accession, and went abroad, but in 1556 was treacherously seized in Belgium, and brought to the Tower. Fear of the stake induced him to abjure Protestantism, and fresh lands were given to him in the place of those he had forfeited, but his recantation preyed on his mind, and he died in the course of the following year, 13th September 1557. Of more than thirty Latin and English books by him, one is a translation of St Matthew's Gospel (edited by Goodwin, 1843), exemplifying a plan for reforming the language by eradicating all words save those of English origin. See his *Life* by Strype (best ed. Oxford, 1821).

Che-keang, an eastern and maritime province of China (q.v.). Capital, Hang-chow.

Chell'ceræ, a technical term usually restricted to the biting organs which form the first pair of appendages in spiders, scorpions, and other Arachnida.

Chelifer. See BOOK-SCORPION.

Chelmsford, the county town of Essex, at the confluence of the Chelmer and the Cam, 29 miles NE. of London. It has a corn exchange (1857), a shire hall (1792), a grammar-school, founded by Edward VI. in 1551, and a parish church, which, all but the tower and spire, was rebuilt between 1803 and 1878. There is a considerable trade in agricultural produce. On a small island in the Chelmer there has long been a ludicrous mock-election during the county elections. Pop. (1851) 6033; (1881) 9885.

Chelmsford, FREDERIC THESIGER, BARON, born in 1794, was a midshipman in the navy, but exchanged the sea for law, and was called to the bar in 1818. He was knighted and made solicitor-general in 1844, attorney-general in 1845 and 1852, and lord chancellor in 1858 and 1866. He died October 5, 1878.—His son, FREDERIC AUGUSTUS THESIGER, second BARON, was born in 1827, entered the Rifle Brigade in 1844, became major in the Grenadier Guards in 1855, and served through the Crimea, the Indian Mutiny, and the Abyssinian campaign of 1868. He was adjutant-general in Bengal (1869-74), and commanded the forces in the Kaffir war of 1878 and in the unfortunate Zulu war of 1879, having resigned the governorship of Cape Colony. Appointed lieutenant-general in 1882, he was made lieutenant of the Tower of London in 1884.

Chelonia, an order of reptiles including the various forms of tortoise and turtle. Their most distinctive character is the more or less complete inclosure of the body by a dorsal and a ventral shield, of which the former is in part due to a modification of the vertebral spines and of the ribs. Within these shields the head, limbs, and tail can be more or less retracted. The absence of teeth is also very characteristic. The Chelonia include marine, fresh-water, and terrestrial forms; the known living species number about 260, the majority occurring in warm countries; they are represented by numerous fossil forms from the Upper Jurassic onwards. The large family Testudinidae, with oval, horny-plated dorsal shield, includes both terrestrial and marsh forms, such as *Testudo*—e.g. the Greek tortoise, Terrapin, Emys, Chelys; a second small family, Trionychidae, with oval, softer shield, includes river forms, such as the well-known snapping-turtle (*Trionyx ferox*); a third family, Chelonidae, with heart-shaped shield, includes five species of marine turtles—e.g.

Chelone viridis. The order will be chiefly discussed under the titles TORTOISE and TURTLE.

Chelsea, a suburb of London, on the north bank of the Thames, here crossed by bridges to Battersea (q.v.). In the 16th century the village of Chelsea was the residence of Sir Thomas More, Queen Catharine Parr, the Princess Elizabeth, and Anne of Cleves. Afterwards Walpole, Swift, Steele, and Sir Hans Sloane, and, in later years, Leigh Hunt, Carlyle, Rossetti, and George Eliot lived here. In the 18th century Ranelagh was much resorted to, and Cremorne (closed 1877) was at one time a popular attraction. Besides its Hospital, Chelsea has a Royal Military Asylum for soldiers' children, large barracks for the Foot Guards, a botanic garden, water-works (1722) to supply London, a river-pier, and an embankment (1873) extending to Battersea Bridge on the west. The famous 18th-century porcelain is noticed under POTTERY. The borough has returned one member to parliament since 1885, when its limits were greatly reduced. Pop. of parish (1887) 112,316.

CHELSEA HOSPITAL is an asylum for old and disabled soldiers of the British army. The gradual decay of the feudal system rendered it necessary to make some new provision for sick and maimed soldiers, consequently various statutes were passed during the reigns of Elizabeth, James I., and Charles I., throwing their maintenance on their respective parishes, under directions from the county justices. This system was abrogated during the Commonwealth as a matter of policy, and the expense met out of moneys arising from sequestrations of the estates of the vanquished royalists. After the Restoration a new act was passed (1662) again throwing their maintenance on the parishes, but this was so burdensome that it was never re-enacted. Sir Stephen Fox, the first paymaster-general of the forces, who had long been an exile in France, and was no doubt well acquainted with the erection in 1671 of the Hôpital des Invalides at Paris, first suggested the building of Chelsea Hospital. The foundation stone was laid by Charles II. in 1682, and the building, designed by Wren, was opened in 1692.

The funds for its lands and buildings, and for many years the maintenance of its inmates, were derived chiefly by deductions from the pay of the troops themselves—viz. 1s. in the £1, as well as one day's pay in each year. Since 1783 it has, however, been almost entirely supported by annual parliamentary grants. All Pensions (q.v.) granted to soldiers are awarded by the Commissioners of Chelsea Hospital, who are appointed by the crown. Originally it was contemplated that all pensioners would become inmates of Chelsea Hospital, but this was soon found impossible, and thus those who could not gain admittance were granted allowances termed out-pensions. The out-pensioners in 1888 numbered 87,703 men, including negroes in the West Indies and West Africa, Maltese, Singhalese, and Lascars, and were estimated to cost £1,770,000. The in-pensioners numbered about 550. They are selected from such out-pensioners as desire to become inmates, according to merit, age, and sufferings from wounds or other disabilities, and are provided with board, lodging, clothing, including the well-known red coat and cocked hat, nursing and medical attendance, together with a small weekly allowance in money according to rank. The in-pension vote for the year 1888-89 amounted (including, however, charges relating to the grant of out-pensions, but excluding cost of repairs to buildings, &c.) to £27,083, against which there is to set off the amount of the out-pensions, which must by statute be surrendered on admission. Those within can at any time become out-pensioners

again, and there are always very many men seeking the position so vacated. Chelsea Hospital is locally known as 'Chelsea College'—the Hospital having been erected nearly on the site of James I.'s short-lived 'College for Religious Controversy' (1610). See the official *Early History of the Royal Hospital at Chelsea* (1872), and Martin's *Old Chelsea* (1888).

Chelsea in Massachusetts, U.S., is a north-eastern suburb of Boston, from which it is separated by the estuary of Mystic River (see BOSTON). Pop. (1870) 18,547; (1880) 25,709.

Cheltenham, a fashionable watering-place of Gloucestershire, on the Chelt, a little affluent of the Severn, 44 miles NNE. of Bristol, 47 SSW. of Birmingham, and 121 WNW. of London (by road only 95). It lies in a picturesque and fertile valley, on the east and south-east half encircled by the Cotswolds. A saline spring was discovered here in 1716, and from a mere village the place gradually increased till 1788, when the benefit derived by George III. from its waters suddenly made it a resort of fashion. The four spas—Royal Old Well, Montpellier, Pittville, and Cambray—are all saline but the last, which is chalybeate; they are deemed efficacious for liver complaints and dyspepsia. With its squares, crescents, and terraces, its gardens and promenades, its clubs and pump-rooms, its August 'cricket week,' its healthy climate, the cheapness of living, and the happy absence of manufactures, the town offers many attractions both to visitors and residents, the former largely foxhunters in winter, the latter retired Anglo-Indians. It is, besides, a great educational centre, the seat of the Proprietary College, for 700 boys, founded in 1840, and occupying a splendid Tudor pile of 1843; a grammar-school (1586; reconstituted 1883); a large ladies' college (1854); a Church of England training college for schoolmasters (1847); and private schools beyond number. Noticeable buildings are the 14th-century parish church; the Roman Catholic Church (1857), with a spire 205 feet high; the Corn Exchange (1863); and the handsome Free Library. Cheltenham has memories of Lord Tennyson, Frederick Robertson, Sydney Dobell, and Dean Close, under whom (1824-56) it became a stronghold of Evangelicalism. It was incorporated as a municipal borough in 1876, and has returned one member to parliament since 1832, the parliamentary boundary having been extended in 1885. Pop. (1804) 3076; (1841) 31,411; (1881) 50,842.

Chelyuskin, CAPE (formerly *North-east Cape*, and sometimes called *Cape Severo*), the most northerly point of Asia, on a peninsula of the same name, which forms the western arm of the eastern half of the Taimyr peninsula. It is named after a Russian officer who led an expedition thus far in 1742, and here succumbed, with his wife, to the fatigues of the journey; it was not revisited till 1878, when Nordenskjöld, in the *Vega*, spent the 19 and 20th of August here. He found it a low promontory, divided into two parts by a small bay; the lat. of the western is 77° 36' 37" N., that of the eastern 77° 41' N.

Chemical Affinity is the name given to the tendency to combine with one another which is exhibited by many substances; or to the force by which the substances constituting a compound are held together. The tendency of any given element to unite with a number of other elements varies greatly. Chlorine, for instance, unites with great readiness with most metals and with many non-metallic elements, much heat being produced during the union; but it has little or no affinity for, or tendency to combine with, oxygen, so that compounds of chlorine with oxygen can only be obtained by roundabout methods, and are very

liable to sudden and explosive decomposition into chlorine and oxygen. Where the affinity of elements for each other is great, the compounds produced by their union are decomposed with difficulty, and where the affinity is feeble, decomposition is easily effected. See also CHEMISTRY.

Chemistry. Although chemistry has only taken its place as an exact science based upon accurate experimental investigation within a comparatively recent period, yet its origin dates back to the earliest times of philosophical study. It will be convenient to give in the first place a short sketch of the history of chemistry, and then to state some of the principles of the science, illustrating these from the simplest facts. When possible, such illustrations will be chosen as are likely to be not altogether unfamiliar to non-scientific readers.

Historical Sketch.—The word *chemistry* has come to us from the Greek through the Arabic, as shown in our article ALCHEMY. With regard to the chemistry of the ancients, we know that the ancient Egyptians, Phoenicians, Greeks, and Romans were acquainted with a very considerable number of useful substances, and that their processes for preparing some of these did not differ in any essential particular from those now in use. It does not appear, however, that they have left any chemical records behind them, or that they knew anything of the science of chemistry. Several metals were known to, and employed by, these ancient peoples, who were acquainted with processes for reducing them from their ores. Amongst these metals were gold, silver, mercury, copper, tin, lead, and iron; whilst they also knew and worked with brass, although they were not aware that it was an alloy of copper and zinc. Various alloys were employed for bronzes for statues, and these usually contained copper, lead, and tin. The processes for manufacturing soap, starch, glass, leather, various mineral and vegetable pigments, stoneware, and other useful substances, were all known and carried on in very early times; and wine and beer appear likewise to have been prepared and used as beverages long before the process of distillation, which was unknown to the ancients, had been introduced. Vinegar, sulphur, and carbonate of soda were also known.

We find the application in medicine of many chemical products at a comparatively early period, and the Arabians appear to have been the first who tried to prepare new medicines by chemical methods. Geber, who lived in the 8th century A.D., is the most noted of the Arabian chemists, and he has left some writings which show us what was the state of chemistry at that early date. Geber knew, for instance, how to make and distil vinegar and nitric acid, and even sulphuric acid was made and used as a solvent by him. He knew, amongst other substances, white arsenic, borax, common salt, alum, sal-ammoniac (ammonium chloride), copperas (ferrous sulphate), nitre (potassium nitrate), and corrosive sublimate (mercuric chloride), and was acquainted with a number of their properties. He used almost all the kinds of apparatus that were commonly in use down till the 18th century, and understood the processes of distillation, filtration, sublimation, and crystallisation. In one of his works he describes the construction of furnaces for chemical purposes.

From the 8th till the 17th century but little real progress was made in chemistry as a science. The new knowledge that was gained during this period was mainly due to the assiduity of the alchemists, who, in their vain search for the philosopher's stone, necessarily made useful discoveries from time to time. Many of the alchemists so called were mere tricksters who deceived their

dupes by more or less clumsy experiments, which appeared to demonstrate the production of gold from baser metal. Others, however, were really earnest and untiring in their labours, and held the fullest belief in the prospects of the ultimate success of some fortunate worker. The new substances obtained by the alchemists were frequently used in medicine, and it is to these infatuated workers, therefore, that we owe our first knowledge of many potent medicines. The writings of many of the alchemists are preserved, but numbers of them are entirely worthless from a scientific point of view, as the descriptions of processes are mixed up with so much of mystery and extravagance that they present a wholly unintelligible jargon. For more detail, however, regarding this remarkable period in the history of chemistry, see the article ALCHEMY.

As Geber has been called the patriarch of chemistry, so Robert Boyle (1627-91) has been called the father of modern chemistry, since it was Boyle who first tried to free chemistry from the trammels of alchemy and to place it upon a true scientific basis. Boyle in his *Sceptical Chemist* tried to discredit the salt, sulphur, and mercury of the alchemists (as well as the Aristotelian earth, air, fire, and water) as elements or ultimate constituents of substances, and he gave a scientific definition of an element. Boyle was an experimental investigator of considerable skill, and to him we owe the introduction of the air-pump and the thermometer into this country. His experiments upon the physical properties of gases led to the formulation of the law concerning the relation of the volume of a gas to the pressure, which is commonly known as Boyle's Law.

Theory in modern chemistry begins with Becher (1635-82) and Stahl (1660-1734). The latter adopted, with some modifications, a theory propounded by the former concerning elements and compounds, and formulated the phlogiston theory of combustion. The views of Becher and Stahl regarding elements were not so enlightened as those of Boyle, and must be considered as retrograde. Stahl's phlogiston theory (1697) was at once adopted almost universally by chemists, and for fifty years it was held to give the full explanation of the phenomena of combustion. According to this theory phlogiston was a constituent of all combustible substances. When a substance burned, the phlogiston made its escape, and the product of combustion was regarded as the other substance with which the phlogiston had been previously united. When a metal such as lead was heated in the air, it lost its phlogiston, and the oxide formed was looked upon as the other constituent of lead besides phlogiston. The process of reduction of lead from its oxide by means of charcoal was the transfer of phlogiston from the charcoal to the lead. It did not present itself to the adherents of the theory as an absurdity that a metal, in losing its phlogiston on oxidation, gained weight, although some of them at least were aware of the fact. The idea of gain of matter being a necessary accompaniment of gain of weight is so familiar to us that we can scarcely realise that it was not always so regarded. To this may fairly be attributed the persistence with which the phlogiston theory held its ground for so long a period.

The Dutch chemist Boerhaave (1668-1738), who did not accept Stahl's theory, published in 1732 his system of chemistry, which was a compilation of practically all that was known up till that date, collected with great labour from a large variety of alchemical and other writings.

The interval between the introduction of the phlogiston theory and its overthrow by Lavoisier in 1772-85 was one of great advance in chemical

knowledge, and a number of very eminent chemists preceded and were contemporaries of Lavoisier.

In Germany, Marggraf (1709-82) studied the properties of the almost unknown alumina and magnesia, and made considerable advances in the qualitative analysis of substances in solution.

Amongst British chemists of note may be mentioned Hales (1677-1761), who was amongst the first to experiment on gases; Black (1728-99), who in 1756 published his research on *Magnesia Alba*, showing the nature of fixed air or carbonic acid gas, and of the difference between caustic and mild (or carbonated) alkalies; Priestley (1733-1804), who, in addition to his discovery of oxygen in 1774, investigated nitric oxide, nitrous oxide, sulphurous acid, carbonic oxide, hydrochloric acid, and ammonia gases, being specially attracted to the study of gaseous substances and their properties; and Cavendish (1731-1810), who investigated the nature and properties of hydrogen, analysed atmospheric air, and discovered the compound nature and composition of water and of nitric acid.

Lavoisier (1743-94) was one of the ablest chemists of his time, and his labours include a vast variety of subjects. His attack upon, and eventual demolition of the phlogiston theory, and his experiments in connection with his new theory of combustion, occupied him for a considerable number of years. He taught that combustion was the union of the combustible substance with atmospheric oxygen; he was the first to introduce system into chemistry and chemical research; he determined the constituents of a large number of substances, including sulphuric, phosphoric, and carbonic acids, numerous metallic oxides, and many animal and vegetable substances; and he, along with Berthollet, Fourcroy, and Morveau (1737-1816), introduced a new and consistent system of chemical nomenclature. Two contemporary Swedish chemists, Bergman (1735-84) and Scheele (1742-86), must be mentioned before leaving the phlogiston age. Bergman investigated, amongst other things, carbonic acid gas, studied the phenomena of affinity, and made advances in the processes and reagents used in qualitative analysis. Scheele was one of the most laborious chemists of his time. He discovered citric, malic, tartaric, oxalic, lactic, hydrocyanic, arsenic and other acids, and chlorine, besides investigating the nature of a large number of other bodies and independently discovering oxygen.

It was towards the end of the 18th century that the value of quantitative analysis of substances began to be generally recognised. The question as to whether the quantitative composition of a given substance was always the same gave rise to a discussion which lasted for several years, and was at length decided in favour of constant composition.

The researches of Richter (1762-1807) on the quantities of various acids neutralised by a given quantity of a base, and of various bases neutralised by a given quantity of an acid, led him to the general conclusion that the quantities of two acids, a and a' , which form neutral salts, $a\ b$, and $a'\ b'$, with the quantities of two bases, b and b' , are just the quantities required to form two other neutral salts, $a\ b'$ and $a'\ b$. This fundamental discovery was erroneously attributed to Wenzel by Berzelius in 1819, and the error has been carefully perpetuated in a considerable number of text-books since that time (Kopp, *Entwicklung der Chemie in der neueren Zeit*, p. 251).

Berthollet (1748-1822), who was one of the most active opponents of the theory of the constant composition of chemical substances, contributed valuable researches into the laws of chemical affinity, and applied chlorine to processes of bleaching. The processes of chemical analysis were improved, and large numbers of analyses, especially of minerals,

were carried out by Klaproth (1743-1817), Vauquelin (1763-1829), Fourcroy (1755-1809), and others; and many quantitative observations of all kinds were made about the end of the 18th century, all preparing the way for Dalton's statement of the Atomic Theory (q.v.) in 1803-4.

The progress of chemistry during the present century has been immense, and it is not possible to do much more than mention the names of some of the most prominent workers. A stimulus was given to research by the publication of Dalton's atomic theory; and the labours of Gay-Lussac (1778-1850), who experimented with gases, of Dulong (1785-1838), and Petit (1791-1820), who pointed out the relation between specific heats and atomic weights of elements, and of others, supported and amplified Dalton's views.

Wollaston (1767-1829) discovered palladium in 1803, and rhodium in 1804. The first alkaloid (morphine) was obtained pure by Sertürner in 1816, and this led to the discovery of a number of others in a short time.

The decomposition by electricity of the bases potash and soda by Davy (1778-1829) in 1807, and the separation from these of the metals potassium and sodium, threw an entirely new light on the nature of these substances. The metals were more fully investigated by Gay-Lussac and Thénard (1777-1857). Davy is noted also as the inventor of the miners' safety-lamp, and for experiments on the respiration of nitrous oxide and other gases.

Amongst the foremost chemists of the earlier part of the 19th century was the Swede Berzelius (1779-1848), whose careful and exact analyses of mineral substances contributed a good deal to the confirmation of the law of constant proportions and to the fixing of the atomic weights (see ATOMIC THEORY) of the elements. Berzelius was very conservative with regard to new theories, which he declined to accept without putting them to the strictest experimental tests. He formulated the electro-chemical theory of the constitution of salts, introduced great improvements into the methods of quantitative analysis, increased the value of the blowpipe as an aid in mineral analysis, discovered many new substances, and further examined and elucidated points concerning many already known, both inorganic and organic.

The artificial production of urea in 1828 by Wöhler (1800-82) marks the beginning of a new era in the branch of organic chemistry, and enormous strides have been made in this department since that time by Dumas (1800-84), Liebig (1803-73), Laurent (1807-53), Gerhardt (1816-56), Wurtz (1817-84), Kolbe (1818-84), Baeyer, Cannizzaro, Frankland, Hofmann, Kekulé, Williamson, and many others. Advances in general inorganic chemistry and analysis have been made by Leopold Gmelin (1788-1853), H. Rose (1795-1864), Sainte-Claire Deville (1818-81), and Bunsen; whilst in connection with advances in chemical physics may be mentioned Faraday (1791-1867), Mitscherlich (1794-1863), Graham (1805-69), Regnault (1810-78), Andrews (1813-85), and Berthelot. These lists do not include all of even the most prominent names that might be mentioned in connection with each department.

The most striking feature of modern chemistry is the extraordinary development of organic chemistry, the account of one branch of it—the chemistry of the coal-tar products—constituting of itself quite a literature which receives additions every day.

Amongst the most recent triumphs of chemical research may be mentioned the artificial production of indigo and grape-sugar, and the isolation, in sufficient quantities to study its properties, of the hitherto all but unknown element fluorine.

Of the greatest possible interest from a theoretical

point of view is the fact that since 1870 three new elements have been discovered—gallium, scandium, and germanium—the existence of all of which had been predicted, and the properties of which had to a certain extent been described beforehand by Mendeleëff. (See periodic law in article ATOMIC THEORY.)

Of late much attention has been given to measurements of the quantity of heat produced in various chemical changes, notably by Berthelot and Thomsen.

Elementary Principles of Chemistry.—The science of chemistry deals with a certain class of changes which matter undergoes when subjected to particular conditions. Similar treatment may produce very different effects upon different substances, as, for instance, the effect of strong heat upon a piece of quartz, a piece of limestone, and a piece of sugar. The quartz does not suffer any *permanent* change, that is, it has the same properties after it is cold again as it had before the action of heat. The limestone, although not necessarily much altered in appearance, has its properties entirely changed, and what remains is a new kind of matter—quicklime. The sugar melts, darkens, and chars, and becomes quite manifestly changed into more than one new kind of matter, for gaseous products, having the smell characteristic of 'burnt sugar,' go off, whilst a black coaly mass remains.

The first of the above changes is merely a *physical* change, from cold to hot; the other two are *chemical* changes, which result in the production of new kinds of matter having properties entirely different from those of the kinds of matter from which they were obtained. The existence of chemistry depends upon the existence of different kinds of matter, and it is with such different kinds of matter and the change from one kind to another that chemistry has to do.

When the properties of matter are studied, it is found that for chemical purposes all kinds of matter may be divided into two great classes, which are called respectively *elements* and *compounds*. The name element is applied to any kind of matter that has not been proved to be composed of more than one simpler kind of matter. This conception of an elementary substance we owe to Boyle, and it will be noted that some of those substances which are now looked upon as elements (see article ATOMIC THEORY for a list of the 68 known elements) may hereafter be proved to be *compounds*, or kinds of matter composed of more than one simpler kind, just as some substances which were at one time rightly classed as elements (according to Boyle's definition) are now known to be compounds of two or more elements.

The compound nature of a specimen of matter may be proved in one or other (or both) of two ways. One of these methods is called *Synthesis* (q.v.), and consists in building up the compound from the component simpler kinds; the other is called *Analysis* (q.v.), and consists in separating more than one simpler kind from the compound kind.

The distinction between chemical compounds and mere mechanical mixtures is a fundamental one, and must be fully understood. The substance gunpowder, for instance, is an intimate mixture of finely powdered sulphur, charcoal, and saltpetre (potassium nitrate), certain precautions being observed during the mixing in order to avoid explosion. These substances are not combined together chemically in gunpowder, but are only mixed, a fact as to which we can easily satisfy ourselves in various ways. We may examine the gunpowder under the microscope and identify the separate particles of the ingredients; or, by the use of appropriate solvents, we may dissolve out

first the saltpetre and then the sulphur, and thus recover all three ingredients separately. The explosion of gunpowder when heated to a sufficiently high temperature is due to the occurrence of a series of changes of the kind we call chemical, for these changes result in the production of new kinds of matter, gaseous and solid, which possess properties in no way resembling those of sulphur, charcoal, or saltpetre, and from which these substances cannot now be dissolved out.

A mixture possesses to a greater or less extent the properties of its respective ingredients; a compound, on the other hand, has not as a rule any properties resembling those of its constituents. A piece of magnesium wire heated in the air to a sufficiently high temperature takes fire and burns. This is a chemical change in which the metal magnesium combines with the oxygen of the air to form a white, brittle, solid compound called *magnesia* or *magnesium oxide*. This *magnesia* does not in the least resemble either magnesium or oxygen in its properties, and the most powerful microscope fails to reveal particles of either of these substances to our vision.

The Atomic Theory (q.v.) is based upon the assumption that matter of every kind is made up of extremely minute indivisible particles called *atoms*. The atoms which exist in a substance may be all of the same kind, as in elements, or of different kinds, as in compounds. Chemists believe that the element hydrogen consists of *molecules* or aggregates of atoms—each molecule consisting of two atoms; further, that the compound substance water consists of *molecules*, each composed of two atoms of hydrogen and an atom of oxygen united to each other by that force which is called *Chemical Affinity* (q.v.); and that similarly every other compound substance is composed of molecules, each molecule consisting of two or more different kinds of atoms united by chemical affinity. The weight of a new compound formed by the union of two or more substances is in every case equal to the sum of the weights of its constituents. In chemical actions it is only the *kind* of matter which is changed, whilst, as in every physical change, the *quantity* of matter concerned remains constant and unalterable.

It has already been seen that one of the characteristics of the chemical combination of two substances is that the properties of both disappear and are not observable in the compound. Another and a most important characteristic is the evolution of heat, which is a very frequent although not an invariable accompaniment of chemical action. The best examples of this may be seen in the ordinary phenomena of Combustion (q.v.). All combustion, whether it be of magnesium wire, coal, phosphorus, paraffin oil, or a candle, is nothing more than a chemical action accompanied by the evolution of heat and light, oxygen gas of the atmosphere being almost invariably one of the substances taking part in such action.

The conditions under which substances act chemically upon each other are very various for different substances. In the first place, certain substances cannot be got to act upon each other at all. Such substances may have little affinity for each other, as chlorine and oxygen, or no affinity, as fluorine and oxygen. Other substances, again, only act upon each other with difficulty. The main conditions upon which action of one substance upon another depends are the state of physical aggregation and the temperature. Certain chemical actions take place at ordinary temperatures, as, for instance, the combination of chlorine with metallic antimony or copper, or the spontaneous ignition of one of the compounds of phosphorus and hydrogen when brought into contact with oxygen. Other actions

only take place when the temperature of the substances which are to take part in them has been sufficiently raised. Thus magnesium requires to be strongly heated in air before it takes fire; once the action is started, however, the heat given out by the combustion of one part of the magnesium is sufficient to raise another part to the temperature necessary for combustion to go on, and so the change is propagated. Coal-gas only burns in air when it is raised to a bright-red heat. A jet of coal-gas escaping into the air may be easily ignited by applying a brightly red-hot poker, but when the poker cools to dull redness it will no longer ignite the jet. A bar of metallic iron does not undergo any chemical change on exposure to dry air at ordinary temperature, but if iron in the state of very fine powder (a form in which it can easily be obtained by appropriate methods) be thrown into the air, combination at once takes place with the evolution of heat and light. When a piece of iron (say a moderately fine iron wire) is heated to redness in air, combination with the oxygen of the air takes place with the formation of a scale composed of a black oxide of iron, but the quantity of heat given out during the combination is not sufficient to propagate the combustion from particle to particle of the iron after removal of the source of heat. If, however, iron wire be raised to a red heat in an atmosphere of oxygen, it takes fire and burns with great brilliancy. The difference noticed here is due to the presence in the one case, and the absence in the other, of the diluting nitrogen which forms nearly four-fifths of the air by volume.

There are certain chemical actions which in taking place are accompanied, not with evolution, but with absorption of heat. In such cases heat has to be supplied throughout the action, and not merely to start it. This is frequently noticed in the combination of substances which have feeble affinity for each other, and the compounds produced are less stable, or more readily break up into their constituents, than those which are produced with the evolution of heat. In general terms it may be stated that the quantity of heat given out in the formation of a compound is a measure of the stability of the compound. When a given weight of magnesium unites with oxygen to form magnesia, a quite definite and measurable quantity of heat is given out. In order to separate the magnesium from the oxygen again, exactly the same quantity of heat must be supplied. In the case of those substances in the formation of which heat is absorbed, we find, as we should expect, that heat is given out during their decomposition, and that its quantity is exactly that which was absorbed during their formation.

Chemical Notation.—For the purpose of shortly expressing the composition of chemical substances, and for representing chemical changes, chemists employ a system of notation which is in extremely common use. In the table of Atomic Weights (see ATOMIC THEORY) it will be noticed that after the name of each element is placed its *symbol*, which usually consists of the first, or of the first and another letter of the Latin name of the element. Each symbol distinctly indicates the element which it is intended to represent, but it must always be borne in mind that the symbol for an element is not merely a contracted form of its name, but that it stands for a definite quantity of that element, this quantity being the atomic weight expressed in terms of the unit of weight employed. The unit of weight almost universally employed by chemists and scientific men in general is the gramme (see METRIC SYSTEM), and that unit will be adopted for illustrations throughout this article. With the gramme as unit, H stands for 1 gramme of hydrogen, Cl for 35.4 grammes of chlorine, O for 16 grammes of

oxygen, Mg for 24 grammes of magnesium, and so on. In order to represent the composition of a compound, the symbols of the various elements which occur in the compound are written side by side, and this collection of symbols is called a *formula*. Thus, MgO represents 40 ($= 24 + 16$) grammes of magnesium oxide, and HCl is 36.4 ($= 1 + 35.4$) grammes of hydrogen chloride. When a compound contains more than one atom of the same element the symbol for that element is not repeated, but the number of atoms is indicated by a subscribed numeral. Thus the formula for water is written H_2O , which indicates that the molecule of water contains two atoms of hydrogen and one of oxygen; and the formula for sulphuric acid is written H_2SO_4 , which indicates that the molecule of sulphuric acid contains two atoms of hydrogen, one of sulphur, and four of oxygen (besides the quantitative signification of these formulae already mentioned). A number subscribed to a portion of a formula inclosed in brackets multiplies the portion so inclosed. Thus the formula $Ba(NO_3)_2$ represents one atom of barium united to twice the quantity of the group NO_3 , which is represented as united to one atom of potassium in the formula KNO_3 . A number prefixed to a formula multiplies the whole of the formula that follows. Thus $2H_2O$ represents twice the quantity of water represented by H_2O .

Chemical symbols and formulae are used to represent shortly chemical changes. A simple illustration of the method of using them may be given to represent the case of the burning of magnesium. The symbols for the magnesium and the oxygen entering into combination (connected by the sign +) are written on one side of what is called a chemical equation, whilst the product is written on the other side, thus:

The formula for free (or uncombined) oxygen is written O_2 , because a molecule of oxygen is believed to consist of two atoms (see ATOMIC THEORY). In order to represent the element magnesium, the simplest possible formula (Mg) is employed because there is no evidence for writing a more complicated one. $2Mg$ simply represents twice as much magnesium as Mg does.

The above equation when fully interpreted gives a great deal of information about the change which it is intended to represent. It shows that magnesium and oxygen unite with each other (under conditions which are not expressed) to form an oxide of magnesium, and that these elements are united in the compound in the proportions by weight of 24 of magnesium to 16 of oxygen; and, further, it enables us, by applying a simple and easily remembered rule, to calculate the *volume* of oxygen taking part in the action as well as its weight. This rule for ascertaining the volume may be conveniently stated here. From certain theoretical considerations, as well as for convenience in calculations concerning the volumes of gases, chemists write the formulae of gaseous substances in such a way that the quantity of a gas represented by its formula, in terms of any unit of weight, shall occupy, under similar conditions of temperature and pressure, the same volume as two units weight of hydrogen. Thus, the unit being the gramme, H_2 represents 2 grammes of hydrogen, and 2 grammes of hydrogen at standard temperature ($0^\circ C.$) and pressure (760 millimetres of mercury) occupy a volume of 22.33 litres (see METRIC SYSTEM). Similarly, the quantities in grammes of oxygen, carbonic anhydride, and nitrous oxide, represented by their respective formulae, O_2 ($16 \times 2 = 32$ grammes), CO_2 ($12 + 32 = 44$ grammes), and N_2O ($28 + 16 = 44$

grammes), each occupy, when measured at 0° C. and 760 mm. pressure, 22.33 litres. This rule holds for other gases, and also, with a certain qualification, for the vapours of volatile liquids. In the case of the latter, of course, conditions of temperature and pressure must be chosen such that the substance is in the state of vapour; and the quantity in grammes which, as a vapour, occupies the same volume as 2 grammes of hydrogen under the same conditions, is the quantity which the formula is chosen to represent. Thus, the formula H_2O informs us that 18 ($= 2 + 16$) grammes of water occupy, in the form of steam, the same volume as 2 grammes of hydrogen when both are measured at the same temperature and pressure. It must, of course, be understood that the formula for a substance is chosen so as to represent the observed facts. The formula of a volatile liquid is deduced from the determination of the *vapour density* of the liquid; this determination is made by ascertaining the weight of that quantity of the liquid which, when converted into the state of vapour, occupies the same volume as a given weight of hydrogen, both being measured at the same temperature and pressure.

Returning to the equation already given, it will be seen that from it we learn that 48 ($= 2 \times 24$) grammes of magnesium unite to form magnesium oxide with a quantity of oxygen (32 grammes) which at 0° C. and 760 mm. occupies 22.33 litres. What volume this quantity of oxygen would occupy under other conditions of temperature and pressure can be calculated from formulæ deduced from the laws of Charles (relation of the volume of a gas to the temperature) and Boyle (relation of the volume of a gas to the pressure). See further in article GASES.

As there are certain conditions under which chemical combination takes place, so there are definite laws which regulate combination. The first of these has been called the *law of constant proportions*, and it states that any chemical compound always contains the same constituents and in the same proportions. Thus magnesium oxide, MgO , always consists of magnesium and oxygen in the proportions by weight of 24 to 16—one atom of magnesium weighing 24, being combined with one atom of oxygen weighing 16. No compound of magnesium and oxygen containing these elements in any other proportion has ever been obtained. If in preparing magnesium oxide quantities of magnesium and oxygen were employed differing from this proportion, then some either of the magnesium or of the oxygen would remain over after the action, according as the former or the latter had been employed in excess of the right quantity.

Intimately connected with the foregoing law is the *law of multiple proportions*. Whilst certain elements combine with each other in only one proportion by weight, others combine in two, and sometimes more than two different proportions. The law of multiple proportions states that when elements combine in two or more proportions these various proportions can be expressed by simple multiples of the atomic weights of the elements concerned. Thus carbon and oxygen unite with each other to form two different compounds: 12 parts by weight of carbon unite with 16 parts by weight of oxygen to form carbonic oxide, CO ; 12 parts by weight of carbon unite with 32 parts by weight of oxygen to form carbonic anhydride, CO_2 . Here the relation is of the simplest kind, for the one compound contains exactly twice as much oxygen for the same quantity of carbon as the other. Again, iron and oxygen unite with each other to form three different compounds: 56 parts by weight of iron unite with 16 parts by weight of oxygen to form ferrous oxide, FeO ; 112 parts by

weight of iron unite with 48 parts by weight of oxygen to form ferric oxide, Fe_2O_3 ; 168 parts by weight of iron unite with 64 parts by weight of oxygen to form ferrous-ferric oxide, Fe_3O_4 . (This case is not quite so simple as that of the oxides of carbon, for here it is necessary to employ multiples of the atomic weights of both elements concerned in order to see the simplicity of the quantitative relations existing amongst these oxides of iron. The law of multiple proportions is, however, fully illustrated by both series of oxides.)

It may be useful to call attention here to the simple explanation furnished by the Atomic Theory (q.v.) for the occurrence of compounds illustrating this law of multiple proportions. There is no compound intermediate in composition between carbonic oxide and carbonic anhydride. The atomic theory explains this very simply. Under one set of conditions we can obtain a compound of one atom of carbon with one atom of oxygen, whilst under other conditions we obtain a compound of one atom of carbon with two atoms of oxygen, or exactly twice as much. This is why we find such marked intervals in composition between two or more compounds of the same elements. The molecule of one compound cannot differ from that of the other by less than an atom, and the addition of an atom to a molecule necessarily forms a new molecule differing in weight from the old one by the weight of the added atom.

The last law of combination has been called the *law of volumes*. It states that when gases combine to form new compounds, the volumes taking part in the action bear a very simple relation to each other and to the volume of the product if gaseous when all the volumes are measured at the same temperature and pressure. Thus, one volume of hydrogen combines with one volume of chlorine to form two volumes of hydrochloric acid gas; two volumes of hydrogen combine with one volume of oxygen to form two volumes of water vapour; two volumes of carbonic oxide combine with one volume of oxygen to form two volumes of carbonic anhydride, and so forth. The very simple relations of the volumes concerned in these examples are sufficiently manifest, and much greater complexity is not frequently met with.

Chemists divide the elements into two great classes, the typical members of which are very different in their physical and chemical characters. These are *metals* and *non-metals*, and as representative of each class may be mentioned copper and sulphur. The more prominent physical characteristics of metals are the metallic lustre, malleability, ductility, and the property of conducting heat and electricity, all of which are possessed to a more or less marked degree; whilst non-metallic elements as a rule possess these properties to a very limited extent, if at all. Differences in chemical behaviour are also very striking in typical representatives of each group. It must be borne in mind, however, that all the members of each group are not typical, but that there is a gradual transition from one group to the other, and certain of the transition elements possess some of the properties of both groups, as in the cases, for instance, of arsenic and antimony.

With the exception of bromine and fluorine, all the elements enter into combination directly or indirectly with oxygen to form oxides. The oxides produced from metallic elements are quite different in chemical character from those produced from non-metallic elements. We shall look first at the oxides of the metals. Every metal forms one or more oxides, and at least one oxide of every metal is a *basic oxide*—i.e. an oxide which has the properties of a Base (q.v.). A distinction is made

between what are called *anhydrous bases* and *hydrated bases* or *hydroxides*. The oxide of lead, PbO , is an anhydrous base (or basic oxide), whilst the compound obtained by the action of water upon calcium oxide, CaO (a basic oxide, and the only compound of calcium and oxygen known), is called a hydrated base (or hydroxide). The formation of the latter is represented by the equation

The oxides produced from non-metallic elements are very frequently *acid oxides*—i.e. oxides which unite with water to form the class of bodies called *Acids* (q.v.). The oxides themselves are often called *acid anhydrides*, whilst the compounds produced by the action of water upon them are called *acids*, or *hydrogen salts*. When phosphorus burns in air, phosphoric anhydride, P_2O_5 , is obtained. This is a white solid substance which unites with water with the evolution of much heat to form a solution of metaphosphoric acid, or hydrogen metaphosphate:

There are a few acids known which do not contain oxygen, and are not obtainable by the combination of an oxide with water. Examples are hydrochloric acid, HCl , hydrobromic acid, HBr , and hydrocyanic acid, HCN . These are also called hydrogen chloride, bromide, and cyanide respectively.

The two classes of substances, bases and acids, are nearly related to the very large class of *salts*. A salt is a compound which can be obtained, amongst other ways, by the action of an acid upon a base, water being almost invariably eliminated at the same time; and just as we saw that the properties of two elements are totally different from those of the compound formed by their combination, so we find that in the formation of a salt the properties of both acid and base to a great extent or altogether become neutralised and disappear.

If to a solution in water of potassium hydroxide, KHO (which is a powerful base), we add a sufficient quantity of nitric acid, HNO_3 , that is until the liquid on thoroughly mixing does not possess either the acid or the alkaline reaction, we obtain a solution in water of potassium nitrate (saltpetre), and nothing else—the water eliminated in the action simply mixing with that which is already present:

Acids have already been mentioned as hydrogen salts. The above equation shows how hydrogen nitrate is exactly comparable with potassium nitrate—an atom of potassium taking the place of an atom of hydrogen—and a characteristic of all hydrogen salts, or acids, is that they contain hydrogen, which is capable of removal and of having its place thus taken by an equivalent quantity of another metal. In the example above mentioned every 1 part by weight of hydrogen has its place taken by 39 parts by weight of potassium. These quantities of hydrogen and of potassium are equivalent, both being capable of uniting with the group NO_3 . This group is an example of what is called a *compound radical*—i.e. a group of elements which is capable of going as a whole through a series of changes. Acids which contain in their molecule one atom of hydrogen replaceable by another metal are called *monobasic acids*. Nitric acid is thus a monobasic acid, whilst sulphuric acid, H_2SO_4 , is *dibasic*, orthophosphoric acid, H_3PO_4 , is *tribasic*, and so on.

Bases, likewise, are sometimes spoken of as *monacid*, *diacid*, *triacid*, and so on, according as one molecule of the base requires one, two, three,

&c. molecules of a monobasic acid (as nitric acid) to form what is called a *normal salt*, that is, a salt in which all the replaceable hydrogen has been replaced by another metal. Thus potassium hydroxide, KHO , is a monacid base; calcium hydroxide, or slaked lime, $\text{Ca}(\text{HO})_2$, is diacid; bismuth hydroxide, $\text{Bi}(\text{HO})_3$, is triacid, and so on. Equations may make this clearer (see the equation above for a monacid base):

Salts are formed in many cases by the replacement of only a *part* of the replaceable hydrogen of a hydrogen salt by another metal. Such are called *acid salts*, and KHSO_4 is an example. This salt, KHSO_4 , may be looked upon as intermediate between the acid, H_2SO_4 , and the normal salt, K_2SO_4 .

Many salts are known which may be looked upon as bases which have their basic character only partially neutralised by an acid. Such salts are called *basic salts*, and as examples may be mentioned BiONO_3 and $\text{Pb}(\text{OH})\text{NO}_3$. The former is intermediate between the normal nitrate, $\text{Bi}(\text{NO}_3)_3$, and the oxide, Bi_2O_3 , the latter between the normal nitrate, $\text{Pb}(\text{NO}_3)_2$, and the hydrate, $\text{Pb}(\text{OH})_2$. Such basic salts are often produced by the action of water upon the normal salts, as, for instance, in the case of the basic bismuth nitrate:

Salts are looked upon as being composed of metal and *salt radical*, the latter name being given to all of the salt that is not metal. Thus SO_4 is the salt radical of the sulphates, NO_3 the salt radical of the nitrates, &c. This way of looking at salts arises from the phenomena observed when salts are decomposed by Electrolysis (q.v.), metal and salt radical being the primary products of decomposition.

Chemical Nomenclature.—Chemists endeavour to make the nomenclature of compound substances as systematic as possible, and a certain amount of system has even been introduced into the nomenclature of the elements themselves. The oxides of the metals are named after the metal which they contain, as magnesium oxide, MgO ; aluminium oxide, Al_2O_3 ; and the series of salts derivable from these oxides are similarly named after the metal. Thus MgCl_2 is magnesium chloride, and $\text{Al}_2(\text{SO}_4)_3$ is aluminium sulphate. When a metal forms more than one basic oxide, adjectival terminations are employed to distinguish these; thus the two basic oxides of iron are named ferrous and ferric oxides (FeO and Fe_2O_3) respectively, and correspondingly there are ferrous and ferric salts. FeSO_4 is ferrous sulphate; Fe_2Cl_6 is ferric chloride. Acid salts and in general salts which contain more than one metal are named after the metals which they contain, the compound radical NH_4 (ammonium; see AMMONIA) being regarded as a metal for purposes of nomenclature. Thus, KHSO_4 is potassium hydrogen sulphate, whilst $\text{HNaNH}_4\text{PO}_4$ is hydrogen sodium ammonium orthophosphate.

The nomenclature of non-basic metallic oxides has been rendered systematic by the use of names descriptive of the number of atoms of metal and of oxygen contained in the oxide, as, for instance, trimanganic tetroxide for Mn_3O_4 . A considerable number of non-basic oxides, as BaO_2 , PbO_2 , MnO_2 , &c., are somewhat less systematically called *per-oxides*.

The acid anhydrides, which, as has already been stated, are oxygen compounds or oxides of the non-metallic elements, are named after the elements of which they are oxides. As there are frequently two or more such acid anhydrides derived from one

element, different terminations and, where necessary, other devices of nomenclature are employed to distinguish amongst these. Thus there are two acid anhydrides derived from sulphur—sulphurous anhydride, SO_2 , and sulphuric anhydride, SO_3 . The latter unites with water to form sulphuric acid, H_2SO_4 , and it is believed by some chemists that the solution in water of sulphurous anhydride (a gaseous substance) contains at least some of the corresponding sulphurous acid, H_2SO_3 . From sulphuric acid there is derived the series of salts called *sulphates*, from sulphurous acid the series called *sulphites*. It sometimes happens that an acid and series of salts are known of which the corresponding anhydride is unknown, just as the existence of certain acids is doubtful although the corresponding anhydride is known. In other cases series of salts are known, although both the corresponding anhydride and acid are unknown. Certain of these peculiarities, as well as some further forms of nomenclature, are illustrated by the table given below of the compounds corresponding to known or unknown oxides of chlorine :

Oxide.	Acid.	Salt.	Name of salt.
Cl_2O	HClO	KClO	Potassium Hypochlorite.
—	HClO_2	KClO_2	Chlorite.
$[\text{ClO}_2, \text{ not an acid anhydride}]$	—	—	—
—	HClO_3	KClO_3	Chlorate.
—	HClO_4	KClO_4	Perchlorate.

It has recently been proved that the substance described in most text-books as chlorous anhydride, Cl_2O_3 , is really a mixture, and that as yet Cl_2O_3 has not been prepared. The hypothetical chloric and perchloric anhydrides would have the composition Cl_2O_5 and Cl_2O_7 , respectively.

A very large number of salts and other chemical compounds are commonly known by popular names, the latter being frequently of extremely ancient origin. The popular name as a rule conveys no information as to the composition of the substance. For instance, *copperas* (ferrous sulphate, FeSO_4) is not recognised by its name as an iron compound, nor *calomel* (mercurous chloride, HgCl_2) as a mercury compound, nor *litharge* (lead oxide, PbO) as a lead compound. It is the aim to convey, by the systematic name of a substance, the greatest possible amount of information as to its composition. It is not possible to attain to a perfect system of nomenclature, as new discoveries render changes necessary from time to time.

Graphic Formulae.—In addition to representing the composition of a substance by means of formulae, chemists endeavour to express certain ideas as to the *constitution*, or arrangement of the atoms in the molecule of substances by means of *graphic formulae*. It must not be supposed (as has sometimes erroneously been done) that graphic formulae are intended to represent the shape of molecules or the arrangement in space of the atoms constituting such molecules, but simply as a short method of expressing on paper certain facts. No one supposes that a printed word in any modern language is an attempt to draw the object spoken of, or that it is more than a method of representing on paper a given series of sounds, and yet criticism based upon assumption scarcely less absurd, has been directed against graphic formulae. In a graphic formula we have the symbols for the different elements grouped in a particular way, so as (1) to indicate the *valency* (see the article ATOMIC THEORY) of each element, and (2) to express ideas based upon observed facts as to the most likely arrangement of the atoms in a molecule, when various arrangements are conceivable.

The following may be given as simple illustrations of (1) :

$\text{H}-\text{Cl}$, hydrochloric acid; $\text{H}-\text{S}-\text{H}$, sulphuretted hydrogen; $\text{Mg}=\text{O}$, magnesium oxide; $\text{N} \begin{smallmatrix} \text{H} \\ \diagup \diagdown \\ \text{H} \end{smallmatrix}$, am-

monia; $\text{H}-\text{C} \begin{smallmatrix} \text{H} \\ | \\ \text{H} \end{smallmatrix}-\text{H}$, marsh-gas; $\text{H}-\text{C} \begin{smallmatrix} \text{Cl} \\ | \\ \text{Cl} \end{smallmatrix}-\text{Cl}$, chloro-

form; $\text{O}=\text{C} \begin{smallmatrix} \text{Cl} \\ | \\ \text{Cl} \end{smallmatrix}$, phosgene; $\text{O}=\text{C}=\text{O}$, carbonic anhydride; $\text{S}=\text{C}=\text{S}$, carbon bisulphide, &c. The letters representing monovalent atoms are written with one stroke proceeding from them, those representing divalent, trivalent, and tetravalent atoms being written with two, three, and four such strokes respectively.

Illustrations of (2) are :

These two substances illustrate two other points of importance. One of these is the occurrence of the nitrogen atom sometimes *trivalent*, as in ammonia, NH_3 , sometimes *pentavalent*, as in the ammonium salts—e.g. ammonium chloride, NH_4Cl . In ammonium cyanate one atom of nitrogen is represented as *trivalent* and the other as *pentavalent*. The two substances, moreover, illustrate *Isomerism* (q.v.), or the existence of two or more compounds containing exactly the same elements and in the same proportions, and yet differing from one another in chemical and physical properties.

Chemical Changes.—There are several kinds of chemical changes which are of very frequent occurrence, and may conveniently be classified. The simple union of one element with another has already been mentioned, and closely related to this kind of change is the union of a compound with an element or with another compound. Along with these changes may be classed those in which a compound breaks up into two or more elements or simpler compounds, or into one or more of each. All these variations are illustrated by the following equations :

One of the most important kinds of chemical change is that called *double decomposition*. This occurs perhaps most frequently when solutions of salts are mixed with each other, and it is characterised by a mutual exchange of metal and salt radical. If an aqueous solution of sodium chloride be mixed with one of potassium bromide, although no visible change takes place, we have reason to believe that double decomposition goes on to a certain extent, with formation of some sodium bromide and some potassium chloride, whilst some of each of the original salts also remains, a state of equilibrium being eventually established amongst the four salts. If, however, one of the new products formed by double decomposition be insoluble or practically insoluble in water, as soon as any of it is formed it will appear as a *precipitate*, and be thus removed from solution, so that no condition of equilibrium can be established until formation of a precipitate no longer occurs—i.e. until the double decomposition is complete. Thus, if solutions of sodium chloride and silver nitrate be mixed in the proper proportions, the extremely insoluble silver

chloride will be precipitated, and only sodium nitrate will remain in solution. The action may be represented by an equation :

The action of sulphuretted hydrogen on many metallic solutions illustrates double decompositions in which the action is complete, as,

where the mercuric sulphide formed is insoluble in water, and is consequently obtained as a precipitate.

In connection with the subject of double decomposition the bearing of the law of Richter (already mentioned in the historical sketch) may be illustrated. Looking at the quantitative signification of the following equations,

we see that the quantity of chlorine which was united with 39 parts by weight of potassium or 23 of sodium to form a salt is exactly the quantity required to form a salt with 108 parts by weight of silver, whilst, similarly, the quantity of the group NO_3 which was united to these 108 parts by weight of silver is exactly the quantity required to form a salt with 39 parts by weight of potassium or 23 of sodium. The same holds good generally for double decompositions.

Another very important kind of chemical change is the displacement of one element in a compound by another. Chlorine, for instance, displaces the iodine in potassium iodide and takes its place :

The greater affinity of potassium for chlorine than for iodine is the explanation given of this displacement. Displacement of one metal by another is a familiar phenomenon, although the chemistry of what is taking place may not be familiar to all who have seen it. When a piece of bright iron or steel, as a key or the blade of a knife, is dipped into an acidulated solution of cupric sulphate (blue vitriol), a reddish deposit of metallic copper is formed almost immediately upon the surface of the metal. This copper is derived from the cupric sulphate solution; but what is not manifest from observation alone, is that at the same time an equivalent quantity of iron is dissolved away and goes into solution as ferrous sulphate. The action is,

The whole of the copper would eventually be separated from the solution in the metallic state if enough iron were present, and for every 63 parts of copper precipitated 56 parts of iron would go into solution.

Inorganic and Organic Chemistry.—The whole subject of chemistry has been divided into two great divisions, named respectively *inorganic* and *organic*. Made originally to separate from each other the chemistry of purely mineral substances, and that of substances of animal or vegetable origin, which were at the time supposed to be capable of formation only as products of vital processes, this subdivision is retained still mainly as a matter of convenience. The division of organic chemistry is sometimes spoken of now as the chemistry of the compounds of carbon; but this is not a very strict definition, as many carbon compounds occur in nature as purely mineral substances, and having really no connection with organic chemistry, such as numerous mineral carbonates. As has been already stated, it is mainly for convenience that the consideration of the majority of the compounds of carbon is taken as a separate branch, not because of any difference in

the chemical principles involved, but really on account of the very great number of these compounds, and of the great complexity of many of them.

It is in the domain of organic chemistry that the study of the constitution of substances has been most diligently prosecuted, and with the greatest amount of apparent success. The graphic formula which chemists assign to acetic acid (to take a simple example) is,

to express a number of ideas concerning the supposed mode of arrangement of the atoms in acetic acid, deduced from the study of its formation, its decompositions, and the action upon it of various substances. The known facts find suitable expression in the formula, and there is no observation yet made as to the chemical relations of acetic acid which is at variance with the constitution indicated by it. It would not be possible here to quote evidence in favour of a particular constitution for any substance, but it may be stated generally that chemists endeavour to fix the constitution of the simplest compounds on the firmest possible basis, and, in passing from the simple to the more complex, to make secure every step.

The tetravalent character of the carbon atom, and the great facility with which carbon atoms enter into combination with other carbon atoms and with the atoms of other elements, give their impress to the whole of organic chemistry. The graphic formulae of organic substances amply illustrate the former, whilst the syntheses of a long array of simple and complex organic compounds as amply illustrate the latter.

A certain amount of knowledge of chemistry is eminently useful in almost every walk of life. An intelligent knowledge of the chemistry involved in the processes of the kitchen, the dairy, the dye-house, the farm, or the manufactory, places the possessor engaged in any of these processes on a different level from the rule-of-thumb worker, who is as ignorant of the reason for adopting a particular method as he is of the properties of the materials he employs. Technical chemistry deals especially with the application of the principles and processes of chemistry to the arts and manufactures, and it is to those who are engaged in manufactures of almost every kind that a knowledge of chemistry is a particular advantage. It is not a question of expediency alone, but one of absolute necessity that a technical education, including chemistry as one of its principal subjects, should form not the least important part of the equipment for his work of any artisan who is to excel in his employment in intelligence and skill.

In connection with this article should be read the article *ATOMIC THEORY*, which is to a certain extent supplementary to this. *ANIMAL CHEMISTRY* and *VEGETABLE CHEMISTRY* are separately treated. The reader is also referred to the description of each element under its name, to those of the acids under their names, and to the following as amongst the most important of the large number of chemical articles throughout this work :

Acids.	Bases.	Glycerine.	Oxides.
Alcohol.	Bleaching	Isomerism.	Salts.
Alkalies.	Powder.	Isomorphism.	Soap.
Alkaloids.	Distillation.	Lime.	Starch.
Allotropy.	Elements.	Metals.	Sugars.
Analysis.	Ethers.	Oils.	Synthesis.
Aromatic Series.	Fats.	Organic	Water.
Atmosphere.	Fermentation.	Radicals.

Chemists and Druggists. Up to the passing of the Pharmacy Act of 1868 the term chemist and druggist was merely a title descriptive of certain branches of trade, just as 'tailor and clothier,' or any other such combination. Any one was free so to describe himself and to prosecute that calling to the best of his ability, untouched by any special legislation, either regulative or protective. The class, like the Apothecary (q.v.), was in its beginnings closely allied to, if indeed at all distinguishable from, that of merchants and grocers, and never formed a distinct guild, and, until the Pharmaceutical Society was founded, was without permanent organisation. And owing to the absence in Scotland of the apothecaries, as a class distinguishable from druggists, the history of the latter class in that country does not, at least up to the passing of the Pharmacy Act of 1882, correspond accurately with that of their English brethren. The policy these latter pursued for a long period of their history may be described as purely defensive, and any organisation they formed was in response to some attack from one of the other orders. As early as 1802 such a defensive association was formed, and from 1812 to 1815 engaged in very active opposition to the bill promoted by the 'Associated Apothecaries.' One of the objects of that bill was to bring the chemists and druggists under the control and surveillance of a body consisting chiefly of apothecaries, on which the chemist and druggist was not represented at all. The upshot was that the promoters of the bill introduced a clause into the Act of 1815, which it was understood at the time would completely exempt the chemist and druggist from the operation of the bill. In spite, however, of this understanding, which seems to have been respected for twenty-six years, the bill was in 1841 made use of to punish a chemist and druggist for prescribing medicine, although that was a function which, rightly or wrongly, he had exercised previous to 1815. In 1841 a bill again threatened to subject the chemist and druggist to the control of the apothecaries, but was at length defeated. It now became evident, not only that a permanent society to protect the interests of the craft was necessary, but that the only wise policy was to educate and organise themselves in such a way as would deprive the physicians and apothecaries of any excuse for further interference. This led to the formation of the Pharmaceutical Society of Great Britain, which was founded in 1841 and incorporated by Royal Charter in 1843. As declared in the charter, the main objects of the society were those of 'advancing chemistry and pharmacy and promoting a uniform system of education of those who should practise the same; and also for the protection of those who carry on the business of chemists and druggists;' and to enable it to carry these out successfully the society appointed professors and examiners, and afterwards proceeded to promote a bill in parliament for the recognition and protection of the titles they proposed to confer on those who passed the examinations. This was naturally a work of time, and in the meanwhile an important act in relation to the sale of poisons—viz. the Sale of Arsenic Act (1851)—was passed, and drew the attention of government to the absence of a definite class of persons qualified by training and education to have the custody and sale of poisonous substances intrusted to them; so that this to some extent led up to the passing of

the first Pharmacy Act of 1852. The main result of this act was to create a class of 'Pharmaceutical Chemists,' alone empowered to use and exhibit that or any equivalent title, and consisting, 1st, of those already members of the society; and 2dly, of such persons as should pass the examinations, as conducted by its two Boards in England and Scotland. The bill, as passed, involved no compulsion on any persons to go through these examinations, nor did it confer any privilege or monopoly on the pharmaceutical chemist except the exclusive right to that title. The dispensing of medicines and sale of poisons was still left open to any one who chose to engage in it. Nor was it till the Act of 1868 that the term chemist and druggist came to signify a specially qualified person or one possessing exclusive rights. By that act all persons not in business on their own account prior to 1st August 1868, had (except some who for a time were allowed to pass a 'modified examination') to pass two Preliminary and the Minor Examinations, and after that were entitled to have their names placed on the 'Register of Chemists and Druggists for the United Kingdom;' and no person who was not on that register could legally use the title, or (with certain exceptions in favour of physicians, apothecaries, veterinary surgeons, &c.) sell or dispense certain poisons specified in schedules to the act. Any person wishing to use the style 'Pharmaceutical Chemist,' had to pass a further examination called the 'Major,' and thus arose the two grades in what we may now call, in view of its educational qualification, the profession of pharmacy. See PHARMACY ACTS.

Chemnitz, a town of Saxony, is situated at the base of the Erzgebirge, and at the confluence of the river Chemnitz with three other streams, 51 miles SSE. of Leipzig by rail, and 43 WSW. of Dresden. It is the principal manufacturing town of the kingdom—the 'Saxon Manchester' its townsfolk call it—its industry consisting in weaving cottons, woollens, and silks, and in printing calicoes, chiefly for German consumption. It supplies the world with cheap hosiery, and makes mixed fabrics of wool, cotton, and jute for the markets of Europe and America. It has several extensive machine-factories, producing locomotives and other steam-engines, with machinery for flax and wool spinning, weaving, and mining industry. Created a free imperial city as early as 1125, Chemnitz suffered much during the Thirty Years' War. Pop. (1801) 10,835; (1861) 45,532; (1885) 110,817.

Chemnitz, MARTIN, the most eminent Lutheran theologian in the second half of the 16th century, was born at Treuenbrietzen, in Brandenburg, 9th November 1522. He had a hard struggle with poverty in his early years, and had repeatedly to interrupt his university studies at Frankfort-on-the-Oder and Wittenberg in order to obtain by school-teaching the means of pursuing them; but at length his proficiency in astrology led to his being appointed librarian of the ducal library at Königsberg in 1550, and from that time he devoted himself entirely to theology. In consequence of his opposition to the teaching of Osiander he was obliged to leave Königsberg and proceed to Wittenberg (1553), where he delivered lectures on the *Loci communes* of Melancthon, which were published after his death as *Loci theologici* (1591). He was appointed a preacher at Brunswick in 1554, and 'superintendent' in 1567, and died there 8th April 1586. The chief works of Chemnitz were his *Examen Concilii Tridentini* (4 vols. 1565-73; new ed. Berlin, 1862), which was the first thorough-going criticism of Tridentine doctrine from a Protestant point of view; and his share in preparing and securing the acceptance of the 'Formula of

Concord'—the next in importance to that of Jacob Andreä. His *Corpus Doctrinae Pruthenicum*, written in conjunction with Mörlin (1567), became a standard work of orthodox Lutheranism. In his *De duabus Naturis in Christo* (1571) Chemnitz developed the doctrine of the 'ubiquity' of Christ in a form mediating between Luther and Melancthon. In every other point of his theology he was a steadfast follower of Luther. His life has been written by Pressel (1862), Lentz (1866), and Hachfeld (1867).

Chemnitzia, a large genus of gasteropod molluscs, named in honour of a German conchologist of the 18th century. They have a slender, elongated, many-whorled shell, the whorls striated, a simple semi-oval aperture, and a horny operculum. There are many recent species scattered all over the world. No less than 180 fossil species have been described from the Lower Silurian upwards, but it is probable that different animals with similar shells are included under this one title.

Chemosh, the national god of Moab, called in 1 and 2 Kings 'the abomination of the Moabites.' The derivation of the name is uncertain, the most probable being that of Gesenius, from *kāmash* (= *kābhash*), 'to trample under foot,' with which the Syrian *kemāsh*, 'nightmare,' is connected. Chemosh was essentially one with the Moloch or Milcom ('king') of the Ammonites, and both were simply forms of the Canaanite Baal (q.v.). On the 'Moabite Stone' King Mesha attributes the Israelite successes over Moab to the wrath of Chemosh, and Moab's deliverance to his assistance. His worship was marked by cruel rites and lascivious orgies. Mesha's first-born son was doubtless sacrificed as a burnt-offering to him (2 Kings, iii. 27). Solomon in his later years consecrated 'high places' (*Bāmōth*) to Chemosh in Jerusalem.

Chemulpo, a town on the west coast of Corea, 25 miles by road WSW. of the capital, Söul. It is one of the three treaty ports opened in 1883 to foreign commerce, the volume of which has since steadily advanced, in spite of the drawbacks resulting from the great difference between high and low water here (33 feet), and the want of wharves. In 1886 the imports were valued at \$1,544,000, the exports at \$217,000; and in July 1887 the number of resident foreign merchants had increased from 482 in 1883 to 1175, including 841 Japanese, 298 Chinese, 5 Americans, and 31 Europeans. Since 1885 it has been connected by telegraph with Tientsin.

Chemung Period, name given by American geologists to one of the principal divisions of Devonian time.

Chenab, one of the five rivers which give name to the Punjab, rises in the Kashmir range of the Himalayas, winds through the gorges of Jammu, and enters British territory in Sialkot district. It absorbs the Tavi, forms the boundary between Sialkot and Gujerat districts, and enters Jhang desert, where it runs through a broad cultivated valley. Here its depth varies from 10 feet in the dry season to 16 feet in the rains; but its course often shifts. It unites with the Jhelum at Timmu, afterwards receives the Ravi, and, as the Trimab, joins the Sutlej, 50 miles above Mithankot. Its length is 755 miles.

Chenery, THOMAS, journalist and orientalist, was born in Barbadoes in 1826, and educated at Eton and Cambridge. He was called to the bar, but was soon after sent out as *Times* correspondent to Constantinople, where he remained during the Crimean war. Afterwards he was constantly employed on the *Times* staff until 1877, when he became its editor, a post which he laboriously filled till within ten days of his death. But this was only one side

of his life. As a singularly thorough Hebrew and Arabic scholar he had few equals among his contemporaries, and his translation of the Arabic classic, the *Assemblies of Al Hariri* (1867), led to his appointment to a chair of Arabic at Oxford in 1888. He was one of the company of Old Testament revisers, and besides other works, published an edition of the *Machberoth Ithiel* (1872), a Hebrew version of the 'Assemblies.' He died 11th February 1884.

Chengalpat. See CHINGALPAT.

Chénier, MARIE-ANDRÉ, a distinguished French poet, was born at Constantinople in 1762. He was the third son of Louis Chénier, French consul-general in that city. His mother was a Greek lady of remarkable beauty and accomplishments. While quite a child he was sent to France; and in his thirteenth year he was placed at the Collège de Navarre, Paris. Partly from predilection, and partly through the influence of his mother, Greek literature was from the beginning his special subject of study. At the age of twenty he entered the army, and served for six months in Strassburg as sub-lieutenant; but disgusted with the frivolity of the military life of that day, he returned to Paris, and gave himself up to a strenuous course of study. To this period belong two of his most famous idylls, *Le Mendiant* and *L'Aveugle*. His health giving way, he travelled in Switzerland, Italy, and the Archipelago. In 1786 he returned to Paris, and began several of his most ambitious poems, most of which, however, remained fragments. The most noteworthy are *Suzanne*, *L'Invention*, and *Hermès*, the last being in plan and spirit an imitation of the great poem of Lucretius; for Chénier shared the beliefs of the 18th-century philosophers of France. In 1787 he went to England as secretary to the French ambassador, but seems to have found his residence there as uncongenial as Heine did. Returning to Paris in 1790, he found himself in the ferment of the Revolution. Up to a certain point he gave the movement his ardent support; but alarmed by its excesses he mortally offended Robespierre by certain denunciatory pamphlets. He was thrown into the prison of Saint-Lazare, and after six months was executed on the 25th July 1794, just three days before the close of the Reign of Terror.

Chénier holds in France a somewhat similar position to Keats in England. They suggest each other also by their early deaths, and by a certain affinity of genius. Other pieces of Chénier that deserve special mention are *La Jeune Captive*, *Le Jeune Malade*, and *Versailles*. Sainte-Beuve thus sums up the claims of Chénier: 'Chénier was one of the great masters of French poetry during the 18th century, and our greatest classic in verse since Boileau and Racine.' The best edition of his poems is Joubert's (1883). See Sainte-Beuve, *Critiques et Portraits*, tome ii.; and Becq de Fouquières, *Lettres critiques sur Chénier* (1881).—His younger brother, MARIE-JOSEPH DE CHÉNIER (1764–1811), was an ardent republican, sat in the Legislative Assembly, and wrote satires and heavy declamatory plays.

Chenille (Fr., 'caterpillar'), a thick, velvety-looking cord of silk or wool (and so resembling a woolly caterpillar), used in ornamental sewing and manufactured trimmings.

Chenonceaux, a famous French château, standing partly on an island in the Cher, partly on a bridge spanning the river, near a station 20 miles E. by S. of Tours by rail. It was commenced in 1524 by the Chancellor Thomas Bohier, continued by Diana of Poitiers, and completed by Catharine de' Medici, who richly embellished the building, and surrounded it with a beautiful park.

It passed into the hands of the Condés, and afterwards of Madame Dupin, widow of a *fermier général*, who here was visited by Montesquieu, Bolingbroke, Voltaire, Rousseau, Buffon, and others. The castle is in excellent preservation; it possesses a fine chapel, a theatre, and memorials of its former occupants in furniture, personal relics, ciphers, and a collection of portraits.

Chenopodiaceæ, an order of apetalous dicotyledons usually regarded as reduced types of Caryophyllaceæ, and closely related to Amaranthaceæ, with which some include them as Oleraceæ. They are herbaceous or half-shrubby plants, with simple, alternate, exstipulate leaves, and inconspicuous flowers, hermaphrodite or unisexual, usually wind-fertilised. There are about 500 species, mostly wood-like, and growing in waste places. They are widely diffused over the world, particularly northern Europe and Asia. Beet and spinach are among the best known and most useful plants of the order, but many others are occasionally used as pot-herbs, as some species of *Chenopodium*, Orache (q.v.), &c. The fruit of Strawberry Blite (*Blitum capitatum* and *B. virgatum*), a common weed in the south of Europe and the colder parts of North America, has a sweetish, insipid taste, and some resemblance to a strawberry, from the coherence of the fleshy perianths of a whole head of flowers. The seed of Quinoa (q.v.) is used for food as a kind of grain. Some are aromatic (see CHENOPODIUM). Some inhabit salt-marshes, and abound in soda. See SALTWORT.

Chenopodium, a genus of Chenopodiaceæ, of which some of the common species are well known by the name of Goosefoot, as weeds growing in gardens, on heaps of rubbish, and in waste places. The species are mostly annuals, with entire or toothed leaves, often with a sort of mealy hoariness, and are widely distributed, or becoming naturalised in all climates. The leaves of many species are used as a substitute for spinach, particularly those of the Good Harry, Wild Spinach, Allgood, or English Mercury (*C. bonus-Henricus*), a common wayside perennial, which is still sometimes cultivated; the young shoots are also used as asparagus. *C. intermedium*, *C. album*, &c., annuals, common in waste places, are also excellent substitutes for spinach. *C. Vulvaria* (Stinking Goosefoot), an annual with an odour compared to that of stale salt fish, growing in waste places, especially near the sea, was formerly in popular repute as an antispasmodic and emmenagogue. *C. purpurascens* (Atriplex) is a handsome annual introduced from China. *C. Botrys*, a native of the south of Europe, with pinnatifid leaves resembling those of the oak, and hence called Jerusalem Oak, is in use as an expectorant and anthelmintic. It is agreeably fragrant. *C. ambrosioides* has a strong aromatic odour, is used in Mexico instead of tea, and is occasionally cultivated in France, an infusion of it being deemed useful in nervous disorders. The closely allied *C. anthelminticum*, the Wormseed of the United States, has a strong and somewhat aromatic odour, and a high reputation as a vermifuge, due to the presence of an essential oil. More important than any of the species, as affording a principal article of food in the countries of which it is a native, is Quinoa (q.v.).

Cheops (a Grecised form of *Khufu*) was a king of Memphis in Egypt, belonging to the fourth dynasty, famous as the builder of the largest of the existing pyramids. The date usually assigned to him is about 3000 B.C. His successor was his brother Chephren (*Khafra*), who built the next largest pyramid. See EGYPT, PYRAMIDS.

Chepstow, a river-port of Monmouthshire, a sub-port to Gloucester, on the right bank of the

Wye, 2½ miles from its influx to the Severn estuary, and 17 ENE. of Newport. It lies between bold cliffs, on a slope rising from the river, in the midst of exquisite scenery. Its noble ruined castle, later chiefly than the 12th century, stood two sieges during the great Rebellion, and has been held successively by Fitz-Osbornes, Clares, Bigods, Herberts, and Somersets. The railway crosses the Wye by Brunel's tubular suspension bridge (1852), 600 feet long, and 50 above high-water, the principal span being 300 feet long. Here occurs the highest tide in the British Islands, if not in Europe; though the accounts of it have been frequently exaggerated. In January 1846 it rose 47 feet above low-water mark, but this level, though often approached, is not known to have been exceeded. Pop. (1851) 4295; (1881) 3591.

Cheque is a money order on a banker, payable on demand. It is really a Bill of Exchange (q.v.), and is subject to the provisions of the Act of 1882, which contains special clauses relating to cheques. If it is not presented within a reasonable time, the drawer is discharged should the banker fail, but the holder can claim against the banker's estate. The banker bears the risk of the forgery of the drawer's signature, but is not responsible for a forged indorsement. A cheque is held as payment of a debt until dishonoured on presentation; it is not payable after the drawer's death or bankruptcy.

A *crossed cheque* is an ordinary cheque with two transverse lines drawn across it, which have the effect of making it payable only through a banker. When a particular banker's name is written between the lines, the cheque is said to be *specialty* crossed, and is only payable to the banker whose name it bears. Wanting a particular name, or with the words '& Co.', it is said to be *generally* crossed, and is payable through any banker. An ordinary cheque may be crossed either generally or specialty by the holder. The crossing is a material part of the cheque, and may not be obliterated or altered, except as provided by the Bills of Exchange Act, 1882.

In the United States a cheque is not a bill of exchange, though it has many of its properties. It is not a legal tender, nor is it a payment of debt till honoured at the bank. It has no days of grace, and is due only after presentation. The bank is responsible for paying a forged cheque, and is liable for wrongfully dishonouring it.

Cher, a French river, flowing 200 miles northward and north-westward till it falls into the Loire below Tours. It is navigable from Vierzon. —CHER, to which the river gives its name, is the central department of France. The surface consists of plain and well-wooded hills (1600 feet), and produces corn, fruits, wine, hemp, flax, &c. The climate is mild and pleasant, except in the swampy district in the north, which has, however, been largely drained in late years. Agriculture, sheep and cattle rearing, and bee-keeping, give employment to many. The rivers abound in fish, and wolves are still sometimes seen. Education is backward, nearly two-thirds of the people being unable to read or write. Area, 2770 sq. m.; pop. (1872) 335,392; (1886) 355,349. Bourges is the chief town.

Cherasco, a walled town in the province of Cuneo, North Italy, 37 miles SSE. of Turin by rail. Pop. 3341. In the middle ages Cherasco was one of the chief fortresses of North Italy, but its works were destroyed by the French in 1801. A peace was concluded here between Louis XIII. of France and the Duke of Savoy in 1631, and another between the Sardinian commissioners and Napoleon in 1796.

Cherbourg, a fortified seaport town and arsenal of France, in the department of Manche, at the head of a deep bay on the northern extremity of the peninsula of Cotentin, 70 miles S. of the Isle of Wight, and 230 WNW. of Paris. Begun by Vauban in 1687, the harbour-works and fortifications were pushed on by the great Napoleon, and were supposed to have been completed in 1858 by Napoleon III. at a total outlay of 200 million francs; but less than thirty years after, the French government resolved to spend 49 millions more on the construction of fresh works between 1883 and 1894. The stupendous *digue* or breakwater, inclosing a space of nearly 2000 acres, is described in the article BREAKWATER. In connection with its fortifications, this breakwater assumes an importance that attaches to no other work of the kind in existence. At the apex of the angle formed by the meeting of the two branches of the *digue*, there is a centre fort or battery, measuring 509 feet on the inner line of the parapet, which forms a flat semi-ellipse. The circular forts at the extremities of the breakwater are remarkably well placed for purposes of defence. Behind the centre battery there is an elliptical tower, measuring 225 feet on the major, and 123 feet on the minor axis. The entrances to the harbour are round the ends of the *digue*; and the passages are further defended by the fortifications of the Ile Pélée, and by the batteries of La Roche Chavaignac and Fort Querqueville. A series of coast redoubts, and the large fortifications of Les Flamands, du Homet, Digosville, and Nacqueville, are situated behind this outer zone of defence. 'The arsenal,' says Dr Russell, 'is inclosed by a continuous line of bastion and curtain of a very elevated profile, defended by outworks, wet and dry ditches, and by profuse batteries of the heaviest guns, either in casement or *en barbette*. Wherever you look, you fancy that on the spot you occupy are specially pointed dozens of the dull black eyes from their rigid lids of stone.' The town itself is commanded by La Ronle on the heights behind. The commercial harbour of Cherbourg consists of an outer harbour, 786 feet in length by 654 feet wide, and of an inner basin, 1338 feet long by 416 feet wide. The great inner naval floating-harbour was inaugurated by the Emperor Napoleon in 1858, in presence of Queen Victoria. Entirely cut out of the solid rock, it is 20 acres in area, and is surrounded by building-slips and capacious graving-docks. It is calculated that the roads of Cherbourg cannot, on account of the small depth of the greater portion, shelter more than 25 or 30 sail of the line, and about as many frigates, at one time. The commercial port displays little activity, the principal exports being eggs, butter, and cattle. The town itself is insignificant, the streets being narrow and dirty; the only buildings of note are Trinity Church, founded by the English about 1450, the hôtel-de-ville, and the theatre. There are some manufactures of hosiery, chemicals, lace, and leather, sugar and salt refineries, sawing and flour mills; but the industrial energies of the great bulk of the population are absorbed in the arsenal and dockyards. Cherbourg is a very ancient place; originally *Cesaris Burgum*, in the 11th century it was known under the name of *Carusbur*. In 1758 Cherbourg was taken by the English, who destroyed the naval and military works, and levied a contribution on the town. Pop. (1872) 34,785; (1886) 37,013; or 51,774 with the three suburbs of Tourlaville, Octeville, and Equeurdreville.

Cherbuliez, the name of an influential family at Geneva, which has produced many eminent scholars and men of letters. Its founder was Abraham Cherbuliez, a prosperous bookseller, who

left three sons—(1) ANDRÉ (1795-1874), professor first of Latin, next of Ancient Literature at the Geneva Academy, author of *De Libro Job* (1829), and an *Essai sur la Satire Latine* (1829).—(2) ANTOINE ELISÉE (1797-1869), an eminent publicist; professor of Law and Political Economy at Geneva; afterwards at Paris the redoubtable antagonist, in the pages of the journals, of Proudhon and the socialists; died professor at Zurich; author of *De la Démocratie en Suisse* (1843), *Études sur les Causes de la Misère* (1853), and *Précis de la Science Économique* (1862).—(3) JOEL (1806-70), who succeeded to his father's business, and became well known as editor of the *Revue Critique* (1833 et seq.), and an occasional contributor to the *Revue des Deux Mondes*. His book, *Le Lendemain du dernier Jour d'un Condamné* (1829), was a clever burlesque and more upon Victor Hugo's well-known *tour-de-force* on the question of capital punishment, while his *Genève, ses Institutions, ses Mœurs, &c.* (1867), was a solid contribution to the history of the city. Of the sisters, two made some reputation: the eldest, Madame TOURTE-CHERBULIEZ (1793-1863), wrote tales and novels, among them *Annette Gervais*, and *Le Journal d'Amélie*; and the youngest, ADRIENNE, born in 1804, translated into French the tales of Zschokke and H. von Kleist. See Rambert's *Ecrivains nationaux Suisses* (vol. i. Geneva, 1874).

VICTOR CHERBULIEZ, son of André, was born at Geneva in 1829, and studied there, at Paris, Bonn, and Berlin, first mathematics, then philology and philosophy; after which he lived in Geneva as a teacher, until his call to Paris in 1864 to join the staff of the *Revue des Deux Mondes*. Since 1882 he has been a member of the French Academy. Cherbuliez began his literary career with books which were compounds between fiction and criticism. In the first of these, *A propos d'un Cheval, Causeries Athéniennes* (1860; 2d ed. under the title, *Un Cheval de Phidias*, 1864), beauty in art, and especially in the sculptures of Phidias, is discussed in a series of conversations by the attendants of a French marquise who is visiting Athens; *Le Prince Vitale* (1864) treats in a similar way the subject of Tasso's madness; *Le Grand Œuvre* (1867) contains, with many incongruous enough discussions of social and political questions, an account of the unfortunate attempt of an English baronet to grow a wife for himself. From these the author turned to work which really proved his powers. In 1863 he published *Le Comte Kostia*, a strong and striking novel, which at once found its author an audience. It was followed by a series of novels which, always clever and original, if sometimes mannered and over-inventive, have lifted Cherbuliez into the front rank of contemporary French writers of fiction. His style is brilliant and epigrammatic, his dialogue natural and lively; while he is readable from beginning to end, and his situations are not only full of interest for the moment, but are remembered long. Many of his earlier stories take the form of a narrative by the chief character, but those difficulties in developing a plot in such a method which have been too great for many novelists, M. Cherbuliez has surmounted with consummate art. His best novels, besides those named already, are: *Le Roman d'une honnête Femme* (1866), *L'Aventure de Ladislas Bolski* (1869), *La Revanche de Joseph Noirel* (1872), *Méla Holdenis* (1873), *Miss Rovel* (1875), *Le Fiancé de Mlle. de Saint-Maur* (1876), *Samuel Brohl et C^e* (1877), *L'Idée de Jean Teterol* (1878), *La Ferme du Choquard* (1883), and *La Vocation du Comte Ghislain* (1888). He has published also several volumes of political studies on Germany and Spain, as well as *Hommes et Choses du Temps présent* (1883), a series of papers which appeared in the

Revue des Deux Mondes under the name of 'G. Valbert.' See a study by George Saintsbury in the *Fortnightly Review* for February 1878.

Cheribon, a seaport of Java, on the north coast, 125 miles ESE. of Batavia. It has a considerable trade in coffee, indigo, and teak-wood, and is the residence of a Dutch governor. Pop. 11,000.

Cherimoya, or CHIRIMOYA (*Anona cherimolia*), the most esteemed fruit of Brazil and Peru, now common, and even naturalised in some parts of the East Indies, and other tropical countries of the Old World. It is a fruit of most delicious flavour, is sometimes described as the finest of all fruits, and sometimes as inferior only to the mangosteen. Both flowers and fruit emit a pleasant fragrance, but when the tree is covered with blossom the odour is almost overpowering. The fruit varies from the size of an orange to 16 lb. or upwards in weight. See CUSTARD-APPLE.

Cherkask. See TCHERKASK.

Chernigov. See TCHERNIGOFF.

Cherokees, one of the most civilised of the American Indian tribes, of the Appalachian stock, and formerly the owners of a wide tract of country on either side of the southern Appalachian Mountains. In 1838 the great majority of the tribe were deported from Georgia to west of the Mississippi by the government, and now they occupy about 5960 sq. m. in the north-east angle of Indian Territory. A few still survive in North Carolina. The Cherokees have a written language and a syllabic alphabet of eighty-five characters, invented in 1826 by George Guess or Sequoyah, a half-breed. They number about 17,000.

Cheroots. See TOBACCO.

Cherry (*Cerasus*), a sub-genus of *Prunus* (see PLUM), of which the species and their cultivated varieties yield the familiar stone-fruit of the same name. The most obvious distinction between the cherries and the plums or section *Prunus* proper is that in the former the leaves are conduplicate, in the latter convolute in bud (see CULTIVATION).

Common Cherry :
a, blossom.

Two species are chiefly regarded as the parents of the garden cherries usually cultivated, *P. Avium* and *P. Cerasus*, the former attaining a height of 40 or 50 feet, and having its leaves and peduncles drooping, with small austere fruit; the latter having erect smooth shining leaves and a more juicy fruit, but being a much smaller tree. Both have white flowers in clusters or nearly sessile umbels, and both are generally regarded as natives of middle and southern Europe, if not also of Britain, where they are both at any rate also naturalised. According to the usual reading of Pliny, *P. Cerasus* was, however, introduced by

Lucullus from *Cerasus* in Pontus to grace his triumph after his victory over Mithridates; Belon, however, plausibly identified this as his own cherry-laurel (see LAUREL). In the wild state, both are often called gean (*Fr. guigne*); more accurately, however, this is *P. Avium*. The latter is frequently planted, not only because it is exceedingly ornamental when in flower, but also on account of its value as a timber-tree, being of rapid growth, with firm strong close-grained wood, suitable for the purposes of cabinet-makers, turners, and musical instrument makers. Double varieties of both species are also grown in our shrubberies. The cultivated varieties of the cherry are very numerous, and differ considerably in size, colour, and flavour; opinions hence differ seriously as to their parentage. The fruit is largely eaten fresh, and as an ingredient in preserves, &c.; the woodcutters and charcoal-burners in some parts of France make it a principal ingredient in soups. Besides its use for the dessert and for preserves, the cherry is extensively used for making liqueurs (see KIRSCHWASSER and MARASCHINO). Cherry Brandy is a liqueur made by steeping Morello cherries in brandy; whereas *Kirschwasser* is a spirit distilled from cherries. In some parts of Germany the roads are fringed by avenues of cherry-trees; and the cherry ripens in Norway and East Bothnia as far north as 63° lat. The other species of cherry are numerous. Some species are low or even prostrate shrubs, as *P. chamaecerasus*, the Groatland Cherry of the south of Europe and of Siberia; and *P. pumila*, the Sand Cherry of North America. The name cherry is also shared by the closely allied Bird-cherry (q.v.) and Choke Cherry (q.v.), including the American Wild Cherry, famous for its medicinal bark; the Mahaleb (*P. Mahaleb*) of the south of Europe, famous for the fragrance of its flowers, and grown in pots to make symmetrical pipe-stems; the Capollim (*C.* or *P. capollim*) of Mexico and Peru, famed for the fragrance of its fruit; and the Laurel-cherry (q.v.). The name cherry is also vaguely and popularly applied in different countries to plants of any kind which happen to recall the true cherry, especially by the size, colour, or taste of their fruit; among these, see BARBADOES CHERRY, WINTER CHERRY, &c. Thus the 'Native Cherry' of Australia is the fleshy fruit-stalk of *Ezocarpus cupressiformis* (*Santalaceae*), while the Hottentot Cherry is *Ilex* (*Cassine*) *Maurocenia*. The 'Beech Cherry' or 'Brush Cherry' of Australia is *Trochocarpa laurina* (*Epacridaceae*), and so on.

Cherry-laurel. See LAUREL.

Cherso, an island of Illyria, belonging to Austria, in the Gulf of Quarnero, 13 miles SSW. of Fiume. A bridge unites it with the adjoining isle of Lussin. Area, 127 sq. m.; pop. (1880) 9550. On its rugged hills sheep are fed; there are large forests, and on the coast, wine, olives, and fruits are produced. Cherso, the chief town, on the west side, has a spacious harbour. Pop. 4670.

Cherson. See KHERSON.

Chersone'sus, the ancient name of several peninsulas and promontories in Europe, the most important of which are the Crimea (q.v.), *C. Taurica*; Gallipoli (q.v.), *C. Thracica*; and Jutland (q.v.), *C. Cimbrica*. When we speak of the Chersonese, the Malay Peninsula is usually meant.

Chert, or HORNSTONE, a variety of quartz, always massive, not unlike flint, but more brittle, breaking with a splintery fracture. It is common in limestones of Palæozoic age, but occurs also in Mesozoic strata (Jurassic, Cretaceous), sometimes forms rocks, and often contains petrifications. It passes into common quartz and chalcedony, also

into flint and flinty slate. Its colours are gray, white, red, yellow, green, or brown. The name Chert is sometimes limited to the finer varieties, and the coarser are called Hornstone.—The name Chert is very commonly given to the siliceous concretions which occur as nodules and layers in limestone rocks, much in the same way as flints in the chalk. When these materials exist to such an extent as to render the limestone useless for economical purposes, it is said to be 'cherty.'

Chertsey, a town in Surrey, near the right bank of the Thames, here crossed by a seven-arch bridge (1785), 21 miles WSW. of London. It is irregularly built, chiefly consisting of two long cross-streets, and is surrounded by villas. The chief trade is in malt and flour. Many vegetables are raised for the London market. Chertsey arose in a monastery founded in 666, and refounded in 964 by Edgar for Benedictine monks. Charles James Fox lived on St Anne's Hill, an abrupt elevation about a mile from the town; and the poet Cowley spent the closing years of his life in Chertsey, in a house that is marked with an inscription. Pop. of parish (1861) 6589; (1881) 9215.

Cherub (Heb. *K'rûbh*), in the plural *Cherubim* or *Cherubs*, is the Hebrew name of a winged creature with a human countenance, which in the Scriptures is almost always represented in connection with Jehovah, and especially as drawing his chariot-throne. In Scripture the cherubim appear to be quite distinct from the angels, who are Jehovah's messengers, while the cherubim are found where God himself is personally present, and are the living bearers of God manifesting himself in his glory on the earth. It is possible to trace a development both of their form and their significance. While they are always conceived as living creatures, their perfectly free power of movement seems to suggest a connection with the thunder-clouds which reveal to the world the majesty of God. In the 18th Psalm it is said Jehovah 'rode upon a cherub, and did fly; yea, he flew swiftly upon the wings of the wind;' and elsewhere the clouds are called the chariot of Jehovah. To the Hebrew idea of the cherub (in this aspect of it) is allied the Indian conception of the bird Garuda, the swift bearer of Vishnu, and the swift-winged four-footed bird which in Æschylus carries Oceanus through the ether, as well as the (later) Greek and Roman representations of the griffins bearing Apollo or Artemis. According to Sayce, the word is probably connected with the Assyrian *kirubu*, the name denoting the winged bull which guarded the house from the entrance of evil spirits, and at the same time with *kurubu*, the 'circling' bird—i.e., according to Franz Delitzsch, the vulture. Phœnicia took the idea from Babylonia, and the two cherubs made for Solomon (1 Kings vi. 23-28) were wrought by Phœnician artificers. Cherubim are mentioned in the Old Testament as guards of Paradise; a cherub with a flaming sword hindered the return of the expelled human pair. In the Holy of Holies cherubim wrought in embossed metal were represented above the mercy-seat, or covering of the Ark of the Covenant, so that they appeared to rise out of it. Figures of cherubim were also wrought into the hangings of the Holy of Holies. The cherubim that appear in the visions of Ezekiel and the Revelation of John depart much from the early representations. In Ezekiel they have the body of a man, whose head, besides a human countenance, has also that of a lion, an ox, and an eagle; they are provided with four wings, two of which serve to fly, while the other two cover the body; four human hands and arms are under the wings,

and the whole body, before and behind, and on the hands and wings, as well as the wheels of their chariot, is spangled with innumerable eyes. In the Revelation, four cherubim, covered with eyes, and having six wings, surround the throne of Jehovah; the first has the face of a lion, the second of an ox, the third of a man, and the fourth of an eagle. As the Gospel is a unity, but four-fold, the four elements of the cherub came to be divided among the four evangelists, the human countenance being the symbol of Matthew, the lion of Mark, the ox of Luke, and the eagle of John. Most Jewish writers and Christian Fathers conceived the cherubim as angels; and Dionysius the Areopagite, in his *Celestial Hierarchy*, makes them a separate class in the first hierarchy. Most theologians also considered them as angels, until Michaelis showed them to be a poetical creation. Herder, in his *Spirit of Hebrew Poetry*, compared them to the griffins that watch treasures and other fabulous figures. In Christian art they are generally represented as sexless figures, with wings from the shoulders, the legs also being either covered by wings, or having wings substituted for them. Very often they have also an aureole round the head.

Cherubini, MARIA LUIGI CARLO ZENOBIO SALVATORE, an eminent composer, was born at Florence on the 8th or the 14th September 1760, the tenth of a family of twelve children. He began to study music at the age of six, under his father, and at nine was sent to the academy of Bartolommeo Felici. Church works to the number of seventeen proceeded from his juvenile pen at this period, and were mostly actually performed in Florentine churches. In 1778 he went to Bologna and studied under the famous Sarti for four years, removing with him in 1779 to Milan; here he was grounded in the old Italian contrapuntal style, and also frequently assisted his master in writing minor parts of operas. In 1780 his own first opera, *Quinto Fabio*, was produced at Alessandria, and for the next fourteen years a succession of dramatic works followed. In 1784 he was invited to London, and held the post of composer to the king for one year. In 1785 he visited Paris, and after another short visit to Turin, returned in 1788 to Paris, which remained thenceforth his home. Up to this period his operas had been in the light Neapolitan style of Paisiello or Cimarosa; they are now forgotten. But after his arrival in Paris a change becomes gradually apparent, contemporaneously with and in the same direction as the development of the style of Mozart in *Figaro* and *Don Giovanni*. Cherubini, however, had no opportunity of hearing these works at this time, and advanced quite independently on the same path. This change is already distinguishable in his first Parisian opera, *Demophon*, given in 1788, but is more distinctly developed in *Lodoiska*, which was received in 1791 with astonishment and admiration. Subsequent works were *Elise* (1794), *Medée* (1797), *Les deux Journées* (or 'The Water-carrier,' 1800), his operatic masterpiece, and *Anacreon* (1803). His lofty unbending manner, however, had excited a prejudice against him in the mind of Napoleon. He visited Vienna in 1805, and made the acquaintance of Haydn, Beethoven, and Hummel. Two of his operas were produced there; but the war between Austria and Napoleon cut short his stay, and he returned to France dispirited. In 1808, on a casual visit to Belgium, he entered on a third period of musical activity with the composition of the first of his great church works, the Mass in F. In December 1814 Louis XVIII. made him a knight of the Legion of Honour. Next year he paid a short visit to England which left a bad effect on his health. Shortly after, he succeeded

to the post of *maitre-de-chapelle* to King Louis. The list of his works from this period comprises a Mass in C (1816), and Requiems in C and D (1817 and 1836), all of the highest rank, besides numerous other church pieces, and six string quartets. In 1822 he became director of the Conservatoire of Paris, which his energetic administrative talent soon raised to the greatness it still preserves. His work on counterpoint and fugue appeared in 1835, and remains a standard book. His severe rule over the institution continued till 1842, when, after only a month's retirement, he died on 15th March. The universal feeling in musical Europe at the time was that its foremost figure was gone. Though the greater part of his career was run in Paris, and the most famous French operatic composers of the early part of the century, Boieldieu, Auber, Halévy, &c., came under his instructions, he has not permanently influenced the French school; his music lives and preserves a strong hold rather in Germany, with the musicians of which he has more affinity. His style has been aptly called that of effect, the means employed being unusual harmonic and orchestral combinations, the agreement of the music with the dramatic situation, and a remarkable architectural structure in point of form. He is always careful, however, to keep within orthodox limits. As already indicated, his operas have numerous parallels with those of Mozart; but along with the lustre and polish of skilfully cut gems, they possess also somewhat of their coldness. The emotional element is often strong, but is always dominated by the intellectual. His artistic ideal was a lofty one, and he never stooped from it. His music commanded high admiration from Beethoven, who even took him as a model of style in composition for the voice. His masses and overtures are well known, and frequently performed in this country, and at least *Medée* and the *Deux Journées* have kept a place on the stage. The stern manner of the 'grim Florentine' finds illustration in his stereotyped reply to all requests in connection with his office, 'It cannot be done,' from which, however, he frequently departed; and he inspired almost enthusiastic attachment in many of his pupils. The antagonism between him and Berlioz, on the other hand, is strongly brought out in the memoirs of the latter; and he was prejudiced against Beethoven. See the Life of Cherubini by E. Bellasia (Lond. 1874); and also the more recent Life by M. Arthur Pougin, which appeared first in *Le Ménestrel* (1882-83), and goes far to vindicate him from the repellent asperity with which he has been reproached.

Cherusci, a German tribe first mentioned by Cæsar, whose exact locality is somewhat uncertain, save that they touched the Weser and lay north of the Harz Forest. They are chiefly memorable in connection with their great leader Arminius (q.v.).

Chervil (*Anthriscus Cerefolium*), an umbelliferous plant, which has been long cultivated, especially on the Continent, as a pot-herb, and used in soups and for a garnish, &c. in the same manner as parsley. The leaves have a peculiar, somewhat sweetish, pleasantly aromatic smell and taste, by which the plant may be known from its congener *Anthriscus vulgaris* or *Scandix Anthriscus*, a poisonous weed, whose leaves have a disagreeable smell, and which is also distinguished by its hispid fruit. *A. sylvestris* has large roots, for the sake of which it is cultivated. The allied Venus' Comb or Shepherd's Needle (*Scandix pecten-Veneris*), often found in cornfields, as also *S. australis* of southern Europe, have a similar taste and smell, and are used in the same way on the Continent. Sweet Chervil or Sweet Cicely (*Myrrhis odorata*; *Scandix*

odorata of the older botanists), a native of the south of Europe and of some parts of Asia, common in the neighbourhood of houses in Britain, although probably not a true native, is frequently cultivated in Germany under the name of *Spanish* or *Anise Chervil*. In Scotland the plant is popularly called *Myrrh*. Its smell is considered attractive to bees; and the insides of empty hives are sometimes rubbed with its leaves, to induce swarms to enter. —The species of *Cherophyllum*, coarse weeds, are also called chervil.

Cherwell, a stream falling into the Isis or Thames near Oxford (q.v.).

Chesapeake Bay, in Maryland and Virginia, and dividing the former state into two parts, is the largest inlet on the Atlantic coast of the United States, being 200 miles long, and from 4 to 40 broad. Its entrance, 12 miles wide, has on the north Cape Charles, and on the south Cape Henry, both promontories being in Virginia. The bay has numerous arms, which receive many navigable rivers, such as the Susquehanna on the north, the Potomac, Rappahannock, and York on the west, and the James on the south-west. Unlike the shallow sounds towards the south, this network of gulfs and estuaries, with its noble feeders, affords depth of water for ships of any burden, virtually carrying the ocean up to the wharves of Baltimore and the arsenals of Washington. —For the *Chesapeake* and *Shannon* sea-fight, see BROKE.

Cheselden, WILLIAM, a great surgeon and anatomist, was born in 1688, at Somerby, near Melton-Mowbray, and having in 1711 established himself in London as a lecturer on anatomy, was next year elected a Fellow of the Royal Society. He was afterwards appointed surgeon to St Thomas's, St George's, and Westminster hospitals, where he acquired great reputation, especially by his 'lateral operation for the stone' in 1727 (see LITHOTOMY). In 1728 he operated on a young man born blind, and the successful result of the operation did much to develop the theory of Vision (q.v.). He died at Bath, 10th April 1752. His four works included *Anatomy of the Human Body* (1713), long a textbook on the subject in England; and *Osteology*, or *Anatomy of the Bones* (1733). See an article in the *Asclepiad* (1886).

Chesham, a market-town of Buckinghamshire, 18 miles NW. of London. Pop. of parish (1881) 6502.

Cheshire, a maritime county in the west of England, on the Welsh border, bounded N. by the river Mersey, separating it from Lancashire, and partly also by the Irish Sea. Its greatest length from north to south is 48 miles; greatest breadth from east to west, 32; total area of land and water, 1102 sq. m., of which 76 per cent. is under cultivation. The coast-line is confined to the hammer-headed peninsula, called Wirral, about 8 miles broad, between the estuaries of the Mersey and Dee. The surface forms an extensive nearly level plain between the Derbyshire and Welsh mountains, well wooded, and studded with small lakes or meres. This plain, comprising four-fifths of the surface, rests on new red sandstone, and is crossed, near the middle, by a tract of high ground running south-west from a promontory overlooking the Mersey, near the mouth of the Weaver, to Beeston Castle rock, 366 feet high. On the east border of the county is a line of new red sandstone hills. In the east are large tracts of peat, and much of the county is wet and rushy. Coal-measures appear on the Flintshire border, and also on the borders of Staffordshire and Derbyshire. The chief rivers are the Dee, Mersey, and Weaver, which are navigable. The Dee skirts the county on the west for 55 miles, and the Mersey on the north for 40 miles. The Weaver rises in the east part of the

county, and runs 40 miles west-north-west to the Mersey. In addition to its river navigation, the county has an almost unrivalled system of canals, and contains the greater part of the Manchester Ship Canal. It is well intersected by railways. The chief mineral products are rock-salt and coal. The rock-salt, discovered in 1670, and mined by gunpowder, is found near the Weaver and its branches, especially near Northwich (q.v.), and at Middlewich, Winsford, and Sandbach. Much salt is also made from brine-springs 20 to 40 yards deep. Coal is worked near Chester and on the eastern borders of the county. Lead and copper mining is now almost extinct. In almost every part of the county freestone, limestone, millstone, and marl are found. The climate is moist. The soil is mostly a clayey or sandy loam, with marl and peat, and very fertile. The soil and climate are well fitted for pasturing, and dairy-farming is largely carried on, the county being noted for its cheese (see CHEESE). About 90,000 cows are kept in Cheshire, capable of producing about 15,000 tons of cheese. In the cattle-plague of 1865-66 upwards of 70,000 cattle perished, 36,000 of these being slaughtered as a preventive measure. Pop. (1801) 194,305; (1841) 395,660; (1881) 664,037. There are extensive manufactures in the principal towns, especially Birkenhead, Congleton, Chester (the county town), Crewe, Macclesfield, Stalybridge, and Stockport. The county is formed into eight parliamentary divisions, each returning one member, and includes the parliamentary boroughs of Birkenhead and Chester, with portions of the boroughs of Ashton-under-Lyne, Stalybridge, Stockport, and Warrington. It contains 503 civil parishes, and is mostly in the diocese of Chester. Cheshire has some Roman roads, tumuli, barrows, remains of religious houses, and many old castles and halls. Egbert, in 828, added Cheshire to the Anglo-Saxon kingdom of Mercia. William the Conqueror erected Cheshire into a county palatine, under Hugh Lupus, with an independent parliament and eight barons. Henry VIII. subordinated it to the English crown; but Cheshire did not send representatives to the English parliament till 1549. See Ormerod's *History of Cheshire* (3 vols. 1819; new ed. 1875), and Earwaker's *East Cheshire* (1877).

Cheshunt, a large village of Hertfordshire, 14 miles N. of London. It is famous for its rose-gardens, and is the seat of a college, founded in 1768 by the Countess of Huntingdon (q.v.) at Trevecca in Brecknockshire, and removed hither in 1792. The buildings were much enlarged in 1868. Pop. of parish (1851) 5579; (1881) 7735.

Chesil Bank or **BEACH**, a bank of gravel and shingle extending 16 miles from Bridport harbour and Burton Bradstock to Portland. It varies in height from 20 to 43 feet, and in width from 170 to 200 yards. For some part of its course it hugs the shore, but the Fleet comes between it and the land for nearly 10 miles from Abbotbury, famous for its swannery. Towards its west end the bank is composed of sand, grit, and fine gravel, but the materials get gradually larger and larger as it is followed eastward. Good authorities believe this bank was formed by the sea as a shingle beach in the ordinary way, that it formerly touched the land throughout its entire course, and that it has since been separated from the shore, and converted into a bar, by the denudation of the land behind it. (See map at **BREAKWATER**.)

Chesney, FRANCIS RAWDON, the explorer of the Euphrates, was born in 1789 at Annalong in County Down. He was gazetted to the Royal Artillery in 1805. In 1829 he inspected the route for a Suez canal, which he proved to be practicable.

His first exploration of the route to India, by way of Syria and the Euphrates, was made in 1831, and he made three other voyages with the same object. The idea was taken up by government, who made a grant of £20,000 after his first expedition, but owing to the opposition of Russia it was never brought to a practical issue. He commanded the artillery at Hong-kong from 1843 to 1847. In 1850 he published his *Expedition for the Survey of the Rivers Euphrates and Tigris*, and in 1868 a *Narrative of the Euphrates Expedition*. He died at Mourne, 30th January 1872. General Chesney's Life by his wife and daughter, edited by Stanley Lane-Poole, was published in 1885.—His nephew, Colonel Charles Cornwallis Chesney (1826-76), was the author of the well-known *Waterloo Lectures* (1861), which were delivered by him as professor at Sandhurst.—A younger brother of the latter, General George Tomkyns Chesney, who was born in 1830, was appointed member of the Council of the Viceroy of India in 1886, and is known to be the author of the clever *jeu d'esprit*, *The Battle of Dorking* (1871), and of a remarkable novel, *The Private Secretary* (1881).

Chesnut. See **CHESTNUT**.

Chess (Fr. *échecs*; Ital. *scacchi*; Ger. *schach*; Dutch *schaak*; Low Lat. *ludus scaccorum*. Originally from Persian *shāh*, 'a king,' thus literally 'the game of kings'), a game of skill for two players or parties, played with figures or 'pieces,' which are moved on a chequered board. The game has acquired a great and unique importance throughout the world; mainly, no doubt, in consequence of its extreme difficulty. It is the subject of a most extensive literature, and its study has become rather that of a science than a recreation. The laws governing its play are identical in all countries.

History.—The origin of chess is the subject of an almost hopeless controversy. It has been claimed, by writers and by legends, for China, India, Persia, and recently with some show of reason, by a Spanish archaeologist, for Egypt. As a matter of fact, traces of the game extend beyond history, and are found among races so widely different that any scientific investigation of the matter may now be considered impossible. The game was probably introduced into Western Europe by the Arabs, or about the time of the Arab invasion (8th century); at all events it was known among the cultured classes before the Crusades (1095). As then played, it differed somewhat from modern chess and from the game as played in the East. One of the earliest references to it in literature is in a work, written about 1300, by Jacobus de Cessolis, a preaching friar, and entitled *Liber de moribus hominum et officiis nobilium super ludo Scaccorum*. This work seems to have found its way into several European countries, MS. copies of it existing in various languages. An English translation from the French was printed by William Caxton in 1474-75 under the title of *The Game and Playe of the Chesse*, and was the first book printed with metal types in England. Modern chess—i.e. the game as now played, dates from about the middle of the 15th century. A MS. discovered in the university library of Göttingen and dated 1490 is the earliest treatise extant, although frequent mention of chess is made by earlier poets and writers. The game found its first home in Spain, where Vicent (1495) and Lucena (1497) published two volumes, now of little value, of games. They were succeeded in 1510 by Damiano, a Portuguese, whose work, though restricted to a few openings, evinces considerable genius. It was plagiarised most unscrupulously by several later writers. Damiano was followed by Ruy Lopez, a cleric of Safra in Estremadura, who is perhaps

the most valuable of the earlier masters. His work, first published at Alcalá in 1561, may be said to have laid the foundation of the modern theory of play, and the opening which bears his name is that which modern analysis has shown to be one of the soundest yet invented. Lopez's treatise was republished in Venice in 1584, and from this date the game seems to have left Spain to find a home in Italy. Here should be mentioned Paolo Boi, a native of Syracuse, who, finding no worthy opponent in his own country, made a lengthened tour through the then most civilised part of Europe. He encountered and defeated every master of the game, including the hitherto invincible Ruy Lopez. His genius, added to a prepossessing appearance and a courteous demeanour, gained for him general admiration; he was patronised by Catharine de' Medici and by Sebastian, king of Portugal, both of whom conferred high favours upon him. The early Italian school, which extended from about 1550 to 1620, is identified with the names of Polerio (1590) and his followers, Salvio, Greco, and others. It may claim to be the most versatile and prolific yet founded, some of the most brilliant openings having come down to us from it. At its close, about the time of the Thirty Years' War, the study of chess was somewhat neglected, and there are no writers of note until the middle of the 18th century. At this time, however, two powerful, and to some extent rival, schools sprang up—the later Italian, led by Ercole del Rio and his commentators, Lolli and Ponziani, and the Northern school of Philidor. The former still confined itself to the study of openings and end-games; the latter turned its attention more to the middle game, advocating what is now known as 'play for position.' Both schools, though opposed in theory, were of the greatest practical benefit to students; their work was in a great measure combined by Allgaier, of Eltern, in his well-known treatise published at Vienna in 1795.

Begun in 1745 by Stamma, a Syrian, and led so powerfully by Philidor, the English school had, during this period, been steadily gaining strength and importance. Writers like Sarratt, Cochrane, Lewis, and Walker were doing their best to popularise the game, and they succeeded in giving it a footing in Britain which it has never since lost. Throughout northern Europe its study became general; in France, though there were few analytical writers—Alexandre being the only one of importance—such players as Deschappelles, Boncourt, and De la Bourdonnais earned for the Parisian school a very high reputation; the last-named player was by far the strongest of his day. In Germany, then as now, chief attention was given to theory; there were no very brilliant players, but the analytical work of Bilguer and Von der Lasa still remains the standard. England, however, continued to maintain its supremacy. Some of the greatest European players crossed the Channel and settled in London, and Howard Staunton, who defeated the French champion, St Amant, came to be regarded as the leading player in the world. Up to this time America had produced no player of more than local eminence; but at the congress held at New York in 1858, the first prize in the chief tourney was won by a youth of twenty-one, Paul Morphy (1837-84), of New Orleans. This player, who from the age of ten had shown a remarkable aptitude for the game, is admitted to be the greatest chess genius that has yet appeared. After his victory in New York he came over to Europe, meeting and defeating in turn the strongest players of London and Paris. It must always be a source of regret that the world so soon lost his wonderful power. After his visit to Europe he abandoned the game in order to follow his profession, that of

advocate. He only partially recovered from an attack of insanity, and died at the age of forty-seven. From this time the history of chess ceases to be that of a few celebrated players, and must be gathered from the magazines and weekly newspaper columns devoted to it in nearly every civilised country. Public interest in it has of late years increased with great rapidity, keeping pace, it would seem, with the progress of intellectual development. In England, where at one time or other nearly every great modern player has resided, the game has attained a dignity and importance altogether beyond that of a mere pastime, and its recognition by the state as a means of mental training has been seriously demanded. Every town and many villages have at least one club—London having upwards of twenty; and such centres as Dublin, Glasgow, Liverpool, and Manchester, five or six. There are also numerous county and district associations, holding periodical meetings in different towns in their provinces, and offering prizes for competition among their members. The British Chess Association, the most important federation of this kind, may fairly claim to represent national chess. Having its administrative centre in London, it is governed by a committee of the most eminent players throughout the kingdom, and its masters' tournaments attract the strongest players from the Continent and America. In Germany, where almost equal enthusiasm for chess prevails, every town has its club; there are many state and class associations; national tournaments are held at least once every year, and international tournaments in turn with other countries. One significant association is that of the university and college chess clubs, which, supported by many of the professors and more advanced students, are already beginning to compete with the lay clubs in their respective cities. In France there are yet few provincial clubs, though their number is now increasing. Paris is the centre of a very strong circle of players, and in the *Café de la Régence* possesses the most celebrated chess resort in Europe. The French government has shown its regard for the game by providing prizes in more than one national tournament. Among other European countries where chess is studied, must be mentioned Austria and Italy. Of the former it is sufficient to say that the metropolitan club can (1888) produce ten players (the ordinary match team) who could probably defeat the same number from any club in the world. In Italy the game is played in every town, and the Italian Chess Association holds an annual tournament. In the New World, the United States of America is, as may be supposed, in advance of all other countries. Besides numerous city clubs (New York alone having nine), there are six state associations, and a recently organised federation of the university clubs. In Canada the game has gained entrance into the public schools; there are clubs in nearly every town, and a national association. In Australasia there are state associations in Victoria, New South Wales, and New Zealand. A national tournament has been held with great success, and it is probable will now take place annually in one or other of the chief cities.

Description.—THE BOARD.—Chess is played on a square board divided by intersecting lines into 64 squares. To facilitate calculation, every alternate square is black, or of a dark colour. The board should be placed so that each player has a white square at his right-hand corner.

THE MEN.—There are 32 men: 16 white, or of light colour, and 16 black, or of dark colour. Each player has 8 *pieces* (one king, one queen, two rooks or castles, two bishops, and two knights)

and 8 pawns. The following diagram represents the board and men properly arranged for play :

BLACK.

WHITE.

Fig. 1.

(N.B.—The king and queen occupy the two middle squares, the queen being on the square of her own colour.)

The King, = K, moves only one square at a time, but in any direction.

The Queen, = Q, may move any number of squares in any direction in a straight line.

The Rook or Castle, = R, may move any number of squares, but only in a direction parallel to the sides of the board—not diagonally.

The Bishop, = B, may move any number of squares in a straight line diagonally. (It will be seen that each bishop remains throughout the game on squares of one colour.)

The Knight, = Kt (or sometimes in American literature, S, from the German *Springer*), moves to the next square but one of a different colour from that on which it rests. Its move forms the diagonal of a parallelogram of three squares by two. (The knight is the only piece having power to move over an intervening piece.)

The Pawn, = P, moves one square forward only, but captures diagonally. For its first move, but not afterwards, a pawn may move two squares, but if in doing so it pass an opposing pawn, the latter may take it as if it had moved one square only. A pawn which succeeds in crossing the board must be exchanged for a queen or any other piece of the same colour, except a king.

All pieces, except the knight, can move only across unoccupied squares, and all pieces (not the pawns) capture in the direction of their moves.

The object of the game is to take the opponent's king, and when the king is attacked, warning must be given by the call of 'check.' If the king cannot avoid the 'check'—that is, if he cannot escape capture by his opponent's next move, he is 'check-mate,' and the game is over. The game therefore always stops one move short of the actual capture of the king.

Laws.—Although the main rules governing chess play are identical throughout the world, there are several minor questions awaiting a general settlement. A complete code of laws (which would necessarily be complex), published with approval and authority of the various national associations, has become almost a necessity. Where no published code has been fixed upon, the following may be enforced without injustice:

(N.B.—In cases where no distinction is implied, the word 'piece' is to be understood to include piece and pawn.)

Lots to be drawn for first move, and afterwards throughout a match or sitting each player has the first move alternately, whatever has been the result of the previous game. The player having first move has a right to choice of men. If board or pieces have been wrongly placed at the beginning of a game, the mistake may be rectified before four moves have been made, but not after. A piece touched must be moved, if it can be legally, or unless, before touching it, the player say *f'adoube*, or words to that effect. (If the piece cannot be legally moved, the king must be moved, but may not castle.) If more than one piece be touched, the adversary may select which is to be moved. An enemy's piece touched must be taken if it can be legally; if not, the king must be moved, but may not castle. Moving the king is a penalty enforceable by the opponent, who must, however, enforce it before he makes his next move. A false or illegal move, and all moves made subsequently, must be revoked, and legal moves made in their stead. No penalty can be enforced if the opponent has made a move or touched a piece in reply. If a player move out of his turn, he must retract the move, but may be called upon by the opponent to play the piece touched on his next move. If a player touch more than one square with a piece, he may not, for that move, play it to any of the squares so touched. If he touch *all* the squares to which it can be played, he must play it to any one of them his opponent chooses. In castling, the king must be moved first, or both pieces together. A pawn advanced to the eighth square must be exchanged for a piece (not a king) of the same colour, and the move is not complete until a piece is demanded. It is not necessary to call 'check,' but the player neglecting to do so, cannot enforce a penalty if his opponent does not notice the 'check.' A player may at any time call upon his adversary to mate him within fifty moves, and if at the expiration of such fifty moves, no capture has been made, no pawn moved nor mate given, a draw may be claimed. Bystanders may not interfere unless appealed to by a player, unless board or men have been wrongly placed, or unless a false or illegal move has been made. In the last case, however, they have no right to interfere until a move has been made in reply.

Notation.—The necessity for some method of recording moves and games of chess has been recognised from a very early period. It is to be regretted that no universal notation has been adopted; as it is, the systems which are in vogue are all more or less dependent upon the language of the nation using them. The modern systems of notation are separable into two classes, which differ essentially: The first, that adopted by English and Latin speaking countries (France, Italy, &c.), has reference to the pieces. It is somewhat cumbersome, but is more descriptive and intelligible. The second, adopted by Germany and northern Europe, has reference mainly to the

board. It is more concise and exact than the first class.

The following diagram will explain the English or Latin system of notation :

BLACK															
bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd	bsqd
QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8	QR 8

WHITE.

Fig. 2.

The squares on the first rank are named after the pieces which occupy them at the beginning of the game; thus (beginning at the left hand) the first square is called the queen's rook's square = Q R sq., since it is occupied by the queen's rook. The second square is called queen's knight's square = Q Kt sq.; the third, queen's bishop's square = Q B sq.; the fourth, queen's square = Q sq., and so on. The squares on the first rank are called *home squares*. The files are numbered according to their distance from the home square, and take the latter's title. Thus the squares in front of the king's square are called king's second or K 2, king's third = K 3, and so on to K 8. Each player numbers the squares from his own side of the board, so that each square has two names (White K B square is Black K B 8, Black Q R 4 = White Q R 5, &c.). A reference to the diagram will make this clear.

In recording a game, the moves of White and Black pieces are each arranged in column, the name of the piece is then given, and the square is indicated to which it moves—e.g. :

White.	Black.
1. P to K 4.	1. P to K 4.
2. Kt to K B 3.	2. Kt to Q B 3.
3. B to B 4.	3. B to B 4.
4. B takes P (ch.).	4. K takes B.

Here the figures give the number of the move, and 1 P to K 4 signifies that White for his first move plays a pawn to the king's fourth square. It is not necessary to say *which* pawn, since only one—i.e. the king's pawn—can be moved to the king's fourth square. Black then has to play, and makes a similar move, counting from his side of the board. For his second move, White plays his knight to king's bishop's third square, and again it is not necessary to say which knight, since only the king's knight can move to K B 3. Black's second move is his queen's knight to queen's bishop's third square. White's third move is king's bishop to queen's bishop's fourth square. The student

should follow these moves with a board and men, and will see then that White can only move one of his bishops—i.e. the king's bishop—and can only move it to *one* bishop's fourth square—i.e. queen's bishop's fourth. (The queen's bishop cannot of course move at all, until released by the move of either the queen's pawn or queen's knight's pawn.) Black's third move requires no further explanation. White's fourth move, 4 B takes P (ch.), means that his bishop captures one of the enemy's pawns and gives check. It is not necessary to say which pawn, since only one can be captured—i.e. Black's king's bishop's pawn. For his fourth move, Black has little choice; he must avoid the threat of capture, and he does so by taking the checking piece—i.e. king takes bishop.

The English notation is shortened in some cases as follows, the same moves being recorded in each case :

(a) White.	Black.
1. P - K 4.	1. P - K 4.
2. Kt - K B 3.	2. Kt - Q B 3.
3. B - B 4.	3. B - B 4.
4. B x P (ch.).	4. K x B.

Here the dash - signifies 'to,' and x signifies 'takes.' The numbers of Black's moves are omitted, since they correspond with those of White.

(b) In some cases the dash is omitted, and the moves recorded simply P K 4, Kt K B 3, B B 4, &c.

(c) The moves are arranged in line, White's move being first, thus : 1 P to K 4, P to K 4, 2 Kt to K B 3, Kt to Q B 3, 3 B to B 4, B to B 4, 4 B takes P (ch.), K takes B.

(d) The moves are written in the form of a fraction, White's move being the numerator, and Black's the denominator, and the number of the move is denoted by a figure prefixed—e.g. :

1. $\frac{P-K4}{P-K4}$;	2. $\frac{Kt-KB3}{Kt-QB3}$;	3. $\frac{B-B4}{B-B4}$;	4. $\frac{B \times P(ch.)}{K \times B}$.
--------------------------	------------------------------	--------------------------	---

We give a diagram of the board after the above moves have been played :

Fig. 3.—Position after Black's Fourth Move.

The German notation (known sometimes as Philidor's, from having been used in that master's treatises on chess) consists in denoting the ranks

of squares by a figure, and the files by a letter, in accordance with fig. 4 :

Fig. 4.

Thus, referring to the English system, the White king's square is denoted by *e 1*, the Black queen's square by *d 8*. In the German system all the squares are counted from White's side only. To denote a move, the first letter of the piece is given, then the square on which it stands, and lastly, the square to which it moves. The moves of pawns are not preceded by any initial letter. A capture is denoted by a colon placed after the move, check is represented by †, or a check and capture by ‡. Castling on the king's side is denoted by *O - O*, and on the queen's side by *O - O - O*. Taking the same moves as before, the game would be recorded therefore as follows :

- | White. | Black. |
|---------------------------|--------------------------|
| 1. <i>e 2 - e 4</i> . | 1. <i>e 7 - c 5</i> . |
| 2. <i>Kt g 1 - f 3</i> . | 2. <i>Kt b 8 - c 6</i> . |
| 3. <i>B f 1 - c 4</i> . | 3. <i>B f 8 - c 5</i> . |
| 4. <i>B c 4 - f 7 ‡</i> . | 4. <i>K e 8 - f 7</i> : |

This system may be and is in some cases still further abbreviated by the omission (*a*) of the initial letters of the pieces, or (*b*) of the square from which the piece moves ; and the moves may also be written in line or fractionally as in the Latin system.

TECHNICAL TERMS.—The following list is not exhaustive, only the terms in general use being given :

Blindfold Chess, or *Chess sans voir*, the game played mentally, without sight of board or men. This almost inexplicable feat is not altogether one of memory, as is generally supposed ; it is rather the result of a special faculty not necessarily corresponding with that for ordinary chess. Some great masters, notably Mr J. H. Blackburne, of London, can conduct as many as twelve games blindfold simultaneously ; and most players of first and second rate strength can play at least one in this way.

Castling, a double move allowed once on the part of each player in a game. The rook is moved to the square next the king, and the king is then moved to the other side. Figs. 5 and 6 show the operation of castling :

The conditions under which castling is allowed are : (*a*) That neither king nor rook have been moved ; (*b*) that no piece intervenes ; (*c*) that the king is not in check ; (*d*) that the king does not cross a square commanded by an opposing piece or pawn.

Check, the warning which must be given when the opponent's king is attacked.

Checkmate, a position in which the king cannot avoid capture on his opponent's next move. Checkmate is from the Persian *shāh matt*, 'the king is dead.'

Discovered check, an attack which is opened on the king by the removal of an intervening piece or pawn.

In the diagram (fig. 7) the king is not in check ; but if the rook be moved, the diagonal with the bishop is opened, and the rook is said to 'discover check.'

En passant.—A pawn which, having moved two squares for its first move, and thus passed an opposing pawn, may be taken, on the next move only, by the latter, *en passant*.

En prise.—A piece is said to be *en prise* when it is in a position to be captured by an opposing piece or pawn, and is not properly defended.

Exchange, the capture of a piece in return for the loss of one of equal value. To 'win the exchange'

Fig. 5.—Castling with King's Rook.

Fig. 6.—Castling with Queen's Rook.

is to capture a rook in return for the loss of a bishop or knight. To 'lose the exchange' is to capture a bishop or knight in return for the loss of a rook.

Gambit, a game in which one player, at the beginning, voluntarily sacrifices part of his force (often a pawn) for the sake of an ultimate advantage.

Fig. 7.—Discovered Check.

Padoube, an expression necessary before a piece or pawn may be touched for the purpose of adjustment, &c. The rule otherwise is that a piece or pawn touched must be moved.

Opening.—The various methods of beginning the game have been the subjects of much study, and are so complex as to elude anything like exhaustive analysis. Openings are classed as: (a) *Gambits* (see above), (b) *Games*, in which the line of play does not involve any sacrifice, and (c) *Defences*, which have reference to the line of play adopted by the second player. Openings in which both players move the king's pawn to king's fourth square for their first moves are arbitrarily classed as 'Regular,' all others as 'Irregular.' All openings of repute have distinctive titles, often being named after their inventors or from some country where they are popular. Steinitz Gambit, Scotch Game, French Defence, are examples. The study of openings is most difficult and practically endless, and should not be begun until the student has some practical acquaintance with the game.

Problem, an imaginary position in which the winning line of play is artfully concealed, and has to be discovered in accordance with given conditions.

BLACK (4 pieces).

WHITE (5 pieces). White to play and mate in two moves.

Fig. 8.—Problem by W. Skinkman, Grand Rapids, Michigan, U.S.A.

Queening a pawn, the promotion of a pawn which has crossed the board, to the power of

another piece. (Of course a queen is selected in most cases, as the most valuable piece.)

Stalemate, a position in which the king, though not attacked, cannot move without being subject to capture, and in which no other move by any other piece or pawn is possible. The game in this case is drawn.

Time Limit, a condition of modern play under which each player is compelled to make a certain number of moves (generally twenty) in each hour. The time is recorded by an ingenious arrangement of clocks, one being set going when the other is stopped.

Literature.—The following works on chess may be consulted with advantage: For history and literature, *The History of Chess*, by Forbes; *Quellenstudien zur Geschichte des Schachspiels*, by Dr A. Van der Linde (Berlin, 1880). For laws, &c., *Chess Praxis*, by H. Staunton. For theory, *The Chess Player's Handbook*, by H. Staunton (1847-49), *Handbuch des Schachspiels*, by Bilgner and Von der Laas (Leip. 1843; 6th ed. 1880); *Führer durch die Schachtheorie*, by O. Cordel (Berlin, 1888). For practice, *Cook's Synopsis*; *Morphy's Games*, and *Book of the London Tournament*, 1885. For problems, *The Chess Problem*, by Planck and others. See also the Chess magazines.

Chest, or THORAX, in Anatomy, is the part of the body which lies beneath the neck and above the Abdomen (q.v.), constituting the uppermost of the two divisions of the trunk, or that which contains the heart and lungs. The chest is somewhat conical in form. Its sides are rounded, but in front and behind they are flattened. The apex, or upper end, is truncated, sloping downwards and forwards; of small size, it permits of the passage of the gullet, windpipe, certain large veins and nerves from the neck into the chest, and of certain large arteries out of the chest. The broad or lower end of the cone slopes downwards and backwards, and is shut in by the diaphragm—a large muscular partition which projects upwards from the lower ribs, being convex towards the chest, and concave towards the abdomen. In Respiration (q.v.) the diaphragm descends by its own muscular con-

traction, while at the same time the ribs are drawn upwards and outwards by the intercostal muscles.

The structures forming the walls of the chest are: (1) The backbone or spinal column; (2) twelve pairs of ribs; (3) the sternum or breastbone; (4) the Diaphragm (q.v.); and (5) the intercostal muscles. See SKELETON, SPINAL COLUMN, &c.

The contents of the chest are the heart, the great arteries and veins, the lungs, the trachea or windpipe, the bronchi or branches of the trachea, leading to the lungs, the œsophagus or gullet, and the thoracic duct, or general terminus of the lymphatic system of vessels, by which the chyle and lymph are discharged into the blood. For the organs of the chest, see the cut at ABDOMEN.

The very great importance of these parts to life, and their great liability to deranged action, renders the chest the seat of a large proportion of the diseases which afflict humanity, and especially of those which end in death; for of the three organs which Bichat called the 'tripod of life'—viz. the brain, heart, and lungs—the chest contains two. The diseases of the chest depend in some cases on alterations in its form, as by Rickets (q.v.) and other diseases affecting the bones in early childhood or in youth, as by too tight lacing in girls. What are commonly called chest diseases are mainly those of the lungs and air-tubes, of which

the principal are consumption, pneumonia, pleurisy, and bronchitis. These are treated in special articles: and for the diseases of the heart and other organs of the chest, see HEART, AORTA, OESOPHAGUS, &c. The examination of the chest in disease is largely conducted by Auscultation (q.v.) and Percussion (q.v.). For measurement round the chest, see MAN. See also DIAGNOSIS.

Chest, MILITARY, is a technical name for the money and negotiable securities carried with an army, and intended to defray the current expenses. In the British army it is in the charge of officers of the Army Pay Department.—**CHEST AT CHATHAM** was the name of a fund for maimed and superannuated seamen, administered at Chatham from 1590 till 1803, and subsequently at Greenwich, till superseded by the regular naval pension system.

Chester, an ancient episcopal city, municipal and parliamentary borough, and river-port, the capital of Cheshire, on the right bank of the Dee, 22 miles from the mouth of its estuary, 16 miles SE. of Liverpool, and 179 miles NNW. of London. Chester is one of the most picturesque towns in England. It stands on a rocky sandstone height, and is still surrounded by the entire circuit of its ancient walls, nearly 2 miles round, 7 or 8 feet thick, and forming a promenade with parapets, where two persons can walk abreast. The ancient gateways have been all rebuilt. The castle, with the exception of 'Casca's Tower,' has been removed, its site being occupied by barracks and county buildings. The Dee is crossed by two bridges, the old picturesque bridge of seven arches, and the new or Grosvenor Bridge, with a noble single arch of stone 200 feet in length (see BRIDGE, Vol. II. p. 437). The two main streets cross each other at right angles, and were cut out of the rock by the Romans 4 to 10 feet below the level of the houses. These streets exhibit the curious arrangement called the 'rows': the front parts of their second stories, as far back as 16 feet, form a continuous paved promenade or covered gallery, open in front, where there are pillars and steps up from the street below, with private houses above, inferior shops and warehouses below, and the chief shops of the town within. There are a considerable number of the picturesque old timber houses of the 16th century, and many of the more modern buildings are in the same style of architecture.

Chester Cathedral is an irregular massive structure of crumbling sandstone, 375 by 200 feet, with a massive tower of 127 feet. It was formerly the church of the abbey of St Werburgh, which for 650 years was one of the richest in England. It became a cathedral church after the dissolution of the monasteries. It is of various dates from Norman to Late Perpendicular, its most striking feature being the fine Perpendicular window of the west front. The building has undergone extensive restoration under the direction of the late Sir Gilbert Scott. A part of St John's Church, a ruined Norman edifice, has lately been restored. It was a cathedral church for some years during the 11th century, when the See of Lichfield was temporarily transferred to Chester. The present bishopric of Chester dates from the reign of Henry VIII. Other public buildings are the town-hall,

the Grosvenor Hotel, the general post-office, the free library, and the music-hall. Suburbs of villas have recently arisen outside the walls; and a public park was opened in 1867. On the common called the Roodee there is a racecourse. The huge railway station, with a frontage of 1010 feet, is the centre of several important railways. Chester has manufactures of lead, oil, and chemicals, iron-foundries, and an iron-shipbuilding yard. The making of boots and shoes is an important industry. The navigation of the Dee has lately been greatly improved. The chief exports are cheese, copper, cast-iron, and coal. Pop. (1851) 27,756; (1871) 35,257; (1881) 36,788; (1888) about 38,000. The city is a county in itself. It has returned members to parliament since the reign of Henry VIII., but by the Distribution of Seats Act, 1885, it lost one of its two members.

Chester was *Deva* or *Devana Castra*, an important Roman station, and has yielded many Roman remains—as masonry, coins, inscriptions, fibulae, altars, a hypocaust, and a statue of Pallas. The British name was *Caerleon*: *Chester*, alone or in composition, represents the Anglo-Saxon *Cæster*, from the Roman *Castra*. After the departure of the Romans it was held by Britons, Saxons, and Danes; and in 605 was laid utterly waste by Ethel-frith of Northumbria. It remained an inclosure of waste walls—occupied at times, as in 894, by a body of marauding Danes, till in 908 it was rebuilt by Ethelred of Mercia; and prosperity came after 942. Chester was the last place in England that held out against William the Conqueror; not till

In the Rows, Chester.

its capture (1070) was the duke really king of England. Henry Lupus, nephew of the Conqueror, was created Earl of Chester, and until the time of Henry III. the Earls of Chester had their own courts and parliaments at Chester, with eight subfeudatories and the superiors of the great religious houses, Cheshire being then a county palatine. On the death of John, Earl of Chester, Henry III. made his eldest son Earl of Chester, and since that time the title has usually been held along with that of Prince of Wales by the eldest sons of English sovereigns. Llewelyn ravaged Chester in 1255. The twenty-five famous Chester mysteries or religious plays by Randle, a monk (1250–60), were acted in the church. After a long and memorable siege (1643–46), the inhabitants, who held out bravely for the king, were starved into surrender. A projected Fenian attack on the

castle in 1867 proved abortive. Among the bishops of Chester have been Pearson, Porteus, and Stubbs. Trinity Church contains the graves of Matthew Henry, the biblical commentator, and the poet Parnell.

Chester, a city of Delaware county, Pennsylvania, on the Delaware, 15 miles SW. of Philadelphia by rail, with a military academy, large shipbuilding yards, and manufactures of cotton and woollen goods, engines, &c. Originally called Upland, it was founded by the Swedes in 1643, and is the oldest town in the state. Pop. (1860) 4631; (1880) 14,997.—**SOUTH CHESTER**, a manufacturing suburb, had a pop. of 3664 in 1880.

Chester, JOSEPH LEMUEL, genealogist, born in Norwich, Connecticut, 30th April 1821, was a newspaper editor in Philadelphia, and in 1858 came to England, where he edited the *Registers of Westminster* (1876) and other registers; part of his copy of the Oxford matriculation register has been printed (1887), and his extracts from the Bishop of London's register were published under the title *London Marriage Licenses* (1887). Chester was an LL.D. of Columbia College, and D.C.L. of Oxford, but always retained the title of Colonel, a reminiscence of the honorary post of aide-de-camp to a Pennsylvania governor which he had once held. He died in London, 26th May 1882. See Dean's *Memoir* (1884).

Chesterfield, a municipal borough in Derbyshire, on the Rother rivulet, 12½ miles SSE. of Sheffield by rail. All-Saints' Church (*circa* 1350) has a curious crooked spire, 228 feet high, and 6 feet off the perpendicular; in Trinity Church (1838) is buried George Stephenson. Other buildings are the town-hall (1857), the Stephenson memorial hall, and the grammar-school (1574; rebuilt 1846). There are manufactures of silk, lace, earthenware, and machinery; and the neighbourhood is rich in coal, iron, and other minerals. Brindley's Chesterfield Canal (1776) extends 46 miles to the Trent. Pop. (1851) 7101; (1881) 12,221.

Chesterfield, PHILIP DORMER STANHOPE, EARL OF, statesman, orator, wit, and man of letters, was the eldest son of the third Earl of Chesterfield, and was born in London, September 22, 1694. He studied at Cambridge, made the grand tour, and sat in the House of Commons as member for St Germans in Cornwall from 1716 to 1726, when he became Earl of Chesterfield. In 1730 he was made Lord Steward of the Household. Until then Chesterfield, who was a Whig, had supported Walpole; but being ousted from his office because he had objected to an excise bill introduced by that minister, he went over to the opposition, and proved himself one of Walpole's bitterest antagonists. He joined the ministry formed by the Pelhams in 1744, and was in 1746 one of the principal secretaries of state. In 1748 he was compelled by ill-health and deafness to retire from public life. He was at one time on terms of intimacy with Swift, Pope, and Bolingbroke. Later in life, by obtruding on Samuel Johnson the patronage which he had withheld till the publication of the Dictionary, he drew from the lexicographer the indignant letter which will keep his name in remembrance while English literature is read. Besides writing the well-known *Letters to his Son*, Chesterfield contributed several papers on subjects of the hour to *The Craftsman* and *The World*. He died on March 24, 1773. The object of the *Letters* was to form his natural son, Philip, into an accomplished man of the world. They contain a good deal of shrewd and solid observation, but their teaching is not of an elevating nature. To shine in the world, to conform to the minute code of etiquette which then ruled society, are the ends

on which the writer sets most store. The expression is occasionally coarse, but the worst feature of the book is the manner in which Chesterfield handles the topic of gallantry, a topic to which he recurs with a most disagreeable frequency. His letters were edited by Lord Mahon (5 vols. 1845-53). See Sainte-Beuve's *Critical Essay on Chesterfield* (Eng. trans. 1870), and W. E. Brown- ing's *Wit and Wisdom of Lord Chesterfield* (1874).

Chesterfield Inlet, a narrow gulf penetrating to the westward from the NW. of Hudson Bay, its extreme dimensions being 250 and 25 miles.

Chester-le-Street, a market-town in the county of Durham, near the left bank of the Wear, 6 miles N. of Durham city. The seat of the Bishop of Bernicia from 883 to 995, it has an old collegiate church (restored 1862), with a spire 156 feet high; whilst in the neighbourhood are Lambton, Lumley, and Ravensworth Castles, the seats of the Earls of Durham, Scarborough, and Ravensworth. Coal-mines and ironworks are numerous. Pop. of township (1851) 2580; (1881) 6646.

Chestnut, or CHESNUT (*Castanea*), which must be clearly distinguished from the Horse Chestnut described below, a genus of Cupulifere, closely allied to the Beech (*Fagus*), and distinguished from it by long male catkins, longitudinally set with groups of flowers, a 5-8-celled ovary, and compressed rounded nuts. The name is derived from the town of Castanum, in Thessaly. The Common,

Branchlet, with Catkins, of Common Chestnut (*Castanea vulgaris*):
a, fruit; b, seed.

Spanish, or Sweet Chestnut (*C. vulgaris*), is said to have been first brought from Asia Minor, but has long extended over the south of Europe, where it has become completely naturalised, and forms extensive woods. It is an ornamental and stately, or, in exposed situations, a very spreading tree, of great size and longevity: the famous chestnut-tree of Totworth in England was known as a boundary-mark in the reign of King John; while a yet more celebrated tree on Mount Etna is said to have measured 204 feet in circumference. The timber is durable and hard, and is used in house-building, for making furniture, and for many other purposes. The timber described as chestnut in ancient buildings is usually, however, really oak. The bark is

used for tanning, but is worth only about half the price of oak-bark. Young chestnut-trees are much esteemed for hop and espalier poles. The chestnut is therefore frequently grown in England as coppice-wood; but it succeeds well as a timber-tree even in Scotland, although it does not generally ripen its fruit. In Devonshire, however, and in some other parts of England, it is planted as a fruit-tree. It succeeds throughout all the middle latitudes of Germany, but dislikes a damp foggy atmosphere. It prefers a dry light soil, and succeeds only where there is a dry subsoil. The nuts are generally three in each husk. They form an important part of the food of the poor in the south of Europe, being used either roasted or boiled, and are ground into flour, and made into a kind of bread. They contain 15 per cent. of sugar, and by pressure yield a fermentable sugary juice. When cultivated as a fruit-tree it is generally grafted, by which means the better varieties are secured. A variety with golden-edged foliage, and another with thin thread-like divided leaves, are sometimes cultivated for their foliage. Other species also bear eatable fruits: those of the American Chestnut (*C. americana*), a tree much resembling the common chestnut, and of the Dwarf Chestnut, or Chinquapin (*C. pumila*), a low tree, or more generally a shrub of 7-8 feet high, are used in America.—A number of species are natives of the East. The inhabitants of the mountains of Java eat the fruit of the Silvery Chestnut (*C. argentea*), and the Tungurrut (*C. Tungurrut*), boiled, roasted, like the common chestnut. Both of these are large trees, the Tungurrut reaching a height of 150 feet. Closely akin to the true chestnuts is the Californian Chinquapin (*Castanopsis Chrysophylla*).

The HORSE-CHESTNUT (*Æsculus Hippocastanum*) is a wholly distinct Sapindaceous tree, supposed to have been introduced from Asia about the middle or latter half of the 16th century; and of which the exceptionally magnificent foliage and blossom, rapid growth, stately size, and general effect have made it a favourite among arboriculturists, though the timber is soft and of little value. It forms singularly effective avenues: those of Bushy Park at Hampton Court Palace near London are well known and largely visited, particularly when in

Branch, with Blossom, of Horse-chestnut
(*Æsculus Hippocastanum*):

a, vertical section of single flower; b, fruit; c, a single seed,
its coat partly removed.

flower. The palmate leaves and terminal racemes or panicles need no description, while the characteristic 3-lobed, thick, prickly capsule, with its one or two (rarely three fully developed) beautifully marked and coloured seeds, is among the most familiar recollections of childish treasure-trove in early autumn. Other species and varieties have

also been introduced, of which *Æ. indica* is probably the handsomest. *Æ. rubicunda*, the so-called scarlet-flowered horse-chestnut, although sometimes described as a native of North America, is perhaps only a variety of the preceding. The American species of *Æsculus* and its practically indistinguishable ally, a sub-genus *Pavia*, are popularly termed Buck-eye. None is so beautiful, or at least possesses such a combination of beauties, as the common horse-chestnut; but *P. californica*, although only reaching a height of 12 to 15 feet, has a singular wealth of fragrant blossom. *P. rubra*, with its many varieties, is the Red Buck-eye.

In Queensland the seeds of *Castano-spermum*, a leguminous tree, are sometimes eaten like chestnuts, and so called; similarly is it at the Cape with the seeds of *Brabejum stellatum*, a Proteaceous plant. The so-called water-chestnut of Europe is the curious horned nut of *Tropana nutans* (order Haloragaceæ), and is an article of food in southern Europe, China, and Cashmere. See TRAPA.

Chetham, HUMPHREY (1580-1653), a Manchester merchant and cloth manufacturer, founder of a bluecoat hospital and of a public library at Manchester (q.v.). See BOOK-CLUB.

Chettle, HENRY, a dramatist and pamphleteer of the 16th century, was the editor of *Green's Groat's-worth of Wit* (1592), wrote thirteen plays of considerable merit, and was part author of thirty-five others, including *Robin Hood* in two parts, *Patient Griseld*, *The Blind Beggar of Bethnal Green*, and *Jane Shore*. In Meres's *Palladis Tamia* (1598) he is mentioned as one of 'the best for comedy amongst us.' Of his other works, his *Kind-Hart's Dreame* (1593?) and *England's Mourning Garment* (1603) are of interest, the former as containing an apology undoubtedly intended for Shakespeare as one of those whom Greene had attacked; the latter, a stanza supposed to be addressed to Shakespeare as 'silver-tongued Melicert.' Chettle died about 1607.

Chevalier, an honorary title given, especially in the 18th century, to younger sons of French noble families. Brought up in comparative luxury, and left at the death of their fathers almost entirely unprovided for, these men generally lived at the expense of others, as a sort of aristocratic parasites, even when they did not prefer recourse to such less honourable means of livelihood as gave occasion to the synonym for swindler, *chevalier d'industrie*. In the plays of the 18th century the chevalier is a constant figure.—Both the Old and Young Pretender were called the Chevalier by their partisans.

Chevalier, MICHEL, an eminent French economist, was born at Limoges, January 13, 1806, and was trained as an engineer. At first an ardent St Simonian and busy contributor to the *Globe*, he attached himself to the party of *Enfantin*, and took an active part in the compilation of the famous propagandist *Libre Nouveau*. After six months' imprisonment in 1832, he had the prudence to retract all that he had written in the *Globe* contrary to Christianity and against marriage. Soon after he was sent by Thiers to inquire into the systems of water and railway communication in the United States. In 1837 he published his chief work, *Des Intérêts Matériels en France*. He was made a councillor of state in 1838, and was appointed in 1840 to the chair of Political Economy in the Collège de France. In 1845 he was returned by Aveyron to the Chamber of Deputies. After the revolution of 1848 he made onslaughts that were never met upon the socialism of Louis Blanc in *Questions de Travailleurs*, as well as in the *Revue des Deux Mondes* and the *Journal des Débats*. A number of these vigorous and masterly articles were collected under the titles, *Lettres sur*

l'Organisation du Travail (1848) and *Questions politiques et sociales* (1852). A free-trader in economics, Chevalier in 1860 aided Cobden in carrying into effect the commercial treaty between France and England. For this he was created a senator and Grand Officer of the Legion of Honour. He took an active interest in the great exhibitions at London (1862) and Paris (1867). He died at Montpellier, 28th November 1879.

Chevaux-de-Frise (Fr., 'Friesland horses,' so called as having been first used in Friesland during the wars of the 17th century) is a military obstacle of the form shown in the

Chevaux-de-Frise.

figure. It is difficult to make unless skilled labour and the necessary materials, such as iron railings, gas-pipes or hop-poles, are at hand, but is kept in a fortress as an article of store. The pattern used by the British army consists of a cylindrical iron tube, 6 feet long and about 5 inches in diameter, pierced with 12 holes to receive as many spears of the same length, which are packed in the tube when not required. Several lengths connected by chains may be used as barriers or as obstacles in the ditch of a fort, or in any place where required. It is, however, generally easy to roll them out of the way, though at the siege of Badajoz, during the Peninsular war, one formed of sword-blades fixed into beams of wood, and placed in the breach, was found to be a very serious obstacle by the British storming party.

Chevet. See ARSE.

Cheviot Hills, a mountain-range occupying contiguous parts of the counties of Northumberland and Roxburgh, on the English and Scotch borders, and running 35 miles from near the junction of the Till and Tweed, in the N.E., to the sources of the Liddel, in the S.W. The principal points are Cheviot Hill (2676 feet) and Peel Fell (1964). West of Carter Fell, these hills chiefly consist of Silurian rocks overlaid by Old Red Sandstone, and Lower Carboniferous strata, with which various igneous rocks are associated. The east portion of the range, including higher and more or less conical and abrupt hills, is built up almost exclusively of ancient lava-flows and tuffs (porphyrite and porphyrite-tuff), which are traversed by a mass of augite-granite, and by veins of felsite, dikes of basalt, &c. In the Cheviot Hills are the sources of the Liddel, Tyne, Coquet, and some of the branches of the Tweed. Grouse abound, and the golden eagle is occasionally seen. These hills afford pasture for the Cheviots, a superior breed of sheep. They have been the scene of many a bloody contest between the English and Scotch, and the name is commemorated in that of the famous old ballad of *Chevy Chase*, for the history in which see OTTERBURN. See five articles by Professor James Geikie in *Good Words* (1876).

Chevreul, MICHEL EUGÈNE, a great French chemist, born at Angers, August 31, 1786. At seventeen he went to Paris, where he pursued the study of chemistry at the Collège de France, under the famous Vauquelin, with such zeal and success that at twenty he was allowed to take charge of the laboratory. He next lectured at the Collège Charlemagne, and was appointed special professor of Chemistry in charge of the dyeing department

at the Gobelins. In 1826 he took his seat in the Academy of Sciences, and in 1830 became director of the Museum of Natural History. One of his earliest discoveries was that of margarine, oleine, and stearine in oils and fats. His studies in fatty bodies and his theory of saponification have opened up vast industries. Between the years 1828 and 1864 Chevreul studied colours, publishing important memoirs from time to time. This patriarch of the scientific world, 'le doyen des étudiants de France,' as he loves to be called, has kept up his studies to an age seen by but few. In 1886 the hundredth anniversary of his birth was celebrated with great enthusiasm. A medal was struck, and a grand fête given at the Museum in his honour, while he was presented with his bust by his colleagues at the Academy of Sciences. Chevreul is F.R.S. and a Commander of the Legion of Honour. Besides papers and memoirs innumerable in the learned journals, he has published works on dyeing (1831), on the optical effects of silk stuffs, on colours and their application to the industrial arts (1864), and histories of chemical science (1866) and of theories of matter (1878). His *De la Baguette divinatoire, du Pendule explorateur et des Tables tournantes* (1854), is the best book on the subjects which it treats.

Chevron, in Architecture, a moulding in the form of a succession of chevrons, otherwise called a zigzag moulding. In general, it is characteristic

Chevron or Zigzag, Andover, Hants.

of Norman architecture, but is also found with the pointed arch, during the transition period from Norman to Early English.

CHEVRON, in Heraldry, an ordinary formed of two bands, joined together at the top, and descending to the extremities of the shield in the form of

Chevron. Chevronel. Per Chevron.

a pair of compasses. *Chevronel*, a diminutive—half the size—of the chevron.

CHEVRON is also the name of a V-shaped band of worsted braid or gold lace, worn on the sleeve by non-commissioned officers of the British army as a badge of rank. Four chevrons indicate a sergeant-major or staff-sergeant, three a sergeant, two a corporal, and one a bombardier in the artillery, a second corporal in the engineers, and a lance-corporal in other branches. Good-conduct badges are precisely similar, but the point is upwards instead of downwards. They are worn by non-commissioned officers below the rank of sergeant, and by private soldiers as well. A similar use is made of chevrons in the army of the United States and other countries.

Chevrotains, or MOUSE-DEER (*Tragulidae*), a family of small ungulates, intermediate between true deer and hogs. The family includes two genera, *Tragulus* and *Hyomosciurus*, often confused with musk-deer, with which they have no special connection. As to characters it may be noted that they have no upper front teeth, but well-developed

pointed canines, especially in the males; there are four complete toes on each foot; there are no horns nor musk-glands; the stomach has no distinct manplies, and thus only three chambers; the placenta is diffuse. *Tragulus* is represented by a number of small species from southern and south-eastern Asia, Malay Archipelago, &c.; *T. javanicus* is much eaten. *Hyomoscius* is represented by a single species (*H. aquaticus*) from the west coast of Africa. It is rather larger and stouter than *Tragulus*, and has aquatic habits. The family dates from the Miocene period. See UNGULATES.

Chevy Chase. See OTTERBURN.

Chewing-gum. a preparation the use of which has become a widespread habit in the United States. It is made from a gum called *Chicle*, produced by a Mexican tree allied to the india-rubber tree, and first imported in 1867 with a view to its employment in india-rubber manufacture. The gum is sweetened, and may be flavoured with peppermint, liquorice, tolu, or other flavouring substances, and is now supplied by automatic boxes at railway stations and other public places.

Cheyenne, the capital of Wyoming territory, U.S., situated on the eastern slope of the Laramie Mountains, at the height of 6000 feet above the sea. It is an important station of the Union Pacific Railroad at its junction with the Denver Pacific and Colorado Central railroads, and is 106 miles N. of Denver, and 516 miles W. of Omaha. Coal and iron are found in its neighbourhood. Cheyenne, settled in 1867, had in 1870 a population of 1450; in 1880, 3456; in 1888, about 8000.

Cheyenne Indians, a warlike branch of the Algonquin stock, originally on the Red River of the North, later on the Cheyenne River in Wyoming, and as far south as the Arkansas. From 1861 to 1867 the government had frequent wars and other troubles with them. They are now partially settled in Indian Territory.

Cheyne, GEORGE, physician, was born in 1671 at Methlick, in Aberdeenshire, and, after studying at Edinburgh under Pitcairn, started a London practice in 1702, in which year he was elected a Fellow of the Royal Society. Full living made him enormously fat (thirty-two stone weight), as well as asthmatic, but from a strict adherence to a milk and vegetable diet he derived so much benefit that he recommended it in all the later of his dozen medical treatises, which included *A New Theory of Fevers* (1701); *Philosophical Principles of Natural Religion* (1705); *Essay of Health and Long Life* (1725), and *The English Malady, a Treatise on Nervous Disorders* (1733). Cheyne died at Bath, 13th April 1743.

Cheyne, THOMAS KELLY, one of the foremost Old Testament scholars in England, was born in London, September 18, 1841. Educated at Merchant Taylors' School and Worcester College, Oxford, he carried off among other honours the Chancellor's medal for the English essay, and became Fellow of Balliol College in 1869. He was rector of Tendring in Essex from 1881 to 1885, when he was appointed Oriel professor of the Interpretation of Holy Scripture at Oxford, and Canon of Rochester. He was a member of the Old Testament Revision Company, and has contributed many articles on biblical questions to the magazines and reviews. A critic of ripe scholarship and remarkable clearness in exposition, free from the tendency to rash destructiveness that mars the work of so many of the best contemporary critics in Germany, he has done much to advance biblical science in England without weakening the real buttresses of the faith. His chief books are *The Prophecies of Isaiah* (1880; 3d ed. 1885); *Exposi-*

tion of Jeremiah and Lamentations (1883); and *The Book of Psalms, or Praises of Israel* (1888).

Chhatísgarh is the south-east division of the Central Provinces of India, with an area, including feudatory states, of 39,761 sq. m.; pop. (1880) 4,612,705. It is mainly a vast fertile plateau, and has of late become a great centre of the Indian grain trade. Dongargarh is the capital.

Chiabrera, GABRIELLO, an Italian poet, born at Savona, 8th June 1552. He was educated at Rome under the care of his uncle, after whose death he entered the service of Cardinal Cornaro, but was obliged to leave it for revenging himself upon a Roman nobleman who had wronged him. He married at fifty, and after an easy and well-spent life, died at eighty-five, 14th October 1637. Chiabrera's poetical faculty blossomed late. An enthusiastic student of Greek, he conceived a great admiration of Pindar, and strove not unsuccessfully to imitate him. He was not less happy in catching the naïf and pleasant spirit of Anacreon; his canzonette being distinguished for their ease and elegance, while his *Lettere Famigliari* was the first attempt to introduce the poetical epistle into Italian literature. Chiabrera also wrote several epics, bucolics, and dramatic poems. Collections of his lyrics, under the title *Time*, were published at Rome in 1718 (3 vols.), at Venice in 1737 (5 vols.), and at Milan in 1807 (3 vols.). Prefixed is a naïf but interesting fragment of autobiography.

Chi'na (ancient *Clanis*), a river of Central Italy, originally a tributary of the Tiber, watering the perfectly level Val di Chiana, which its overflow (see CHITSI) rendered once the most pestilential district of Italy. The bed was deepened in 1789-1816, and in 1823 extensive hydraulic works were undertaken for further improving the river-course, and for leading a northern branch, through canals, to the river Arno, a few miles below Arezzo, the southern stream reaching the Tiber through the Paglia at Orvieto. The double stream is 60 miles long, and $\frac{1}{2}$ to 1 mile broad; and the district has since become one of the most fruitful in all Italy.

Chianti, an Italian mountain-range, in the province of Siena, clothed with olive and mulberry trees and vines; the mountain gives name to an excellent red wine grown here.

Chiapas, LAS, a state of Mexico, on the Pacific, adjoining Guatemala. Largely a part of the tableland of Central America, it enjoys a delicious climate; and where the navigable Rio Chiapas cuts through the middle of the plateau, the valleys are among the most fertile portions of the republic, although the country is still almost everywhere clothed with primeval forest. Area, 21,275 sq. m.; pop. (1882) 205,362, chiefly aborigines. Capital, San Cristobal. Near Palenque, one of its towns, are most extensive and magnificent ruins.

Chiaramon'te, a town of Sicily, 30 miles W. of Syracuse, with trade in wine. Pop. 9364.

Chia'ri, a town of Lombardy, 13 miles W. of Brescia by rail, with manufactures of silk. At one time strongly fortified, it is memorable for the victory here of the Austrians, under Prince Eugene, over the French and Spaniards, under Villeroy, 2d September 1701. Pop. 5999.

Chiar-oscuro (Ital.), an artistic term, composed of two Italian words, the one of which signifies light, the other darkness or shadow. But chiar-oscuro signifies neither light nor shadow; neither is it adequately described by saying that it is the art of disposing of both the lights and shadows in a picture, so long as either is regarded apart from the other. It is rather the art of representing light in shadow and shadow in light, so that the parts represented in shadow shall still

have the clearness and warmth of those in light, and those in light the depth and softness of those in shadow. It is not the making of the one die softly and gradually away into the other, but the preservation of both in combination, as we constantly see it in nature, when the light is not the mere glare of the sun striking on a particular object, nor the shadow the entire absence of the influence of light. That the skilful treatment of chiar-oscuro is a matter of extreme difficulty is plain enough from the very small number of artists who ever attain to it. Still, it is a branch of art without the mastery of which no painting can be successful in any department. It is as indispensable in portrait-painting as in the highest departments of ideal arts; and though a just and even a lofty conception of the subject may be distinctly indicated by attention to form alone, it is impossible that its realisation can ever be satisfactorily accomplished by any one who has not mastered this most subtle mode of handling colours. The only mode by which a knowledge of chiar-oscuro can be attained, so as to apply it to practice, is by studying it as exhibited in the works of such painters as Titian, Rubens, Rembrandt, and Correggio.

Chiastolite, a variety of the mineral Andalusite (q.v.).

Chia'vari, a port of Italy, 24 miles ESE. of Genoa by rail, with a number of fine churches and palaces, fisheries, and some trade. Pop. 8582.

Chiavenna, a town of Lombardy, beautifully situated to the north of Lake Como, on the way to the Splügen Pass. Pop. 2848.

Chica, a dyestuff giving an orange-red colour to cotton. It is obtained by boiling the leaves of a species of *Bignonia* (*B. chica*), a climber of the banks of the Cassiquiare and the Orinoco. The Indians use it for painting their bodies. See BIGNONIACEÆ.—**CHICA**, or **CHICHA**, is also the name of a kind of beer made from Maize (q.v.).

Chicacole, a town of the district of Ganjam, in the Madras province, on the Languliya River, 567 miles NE. of Madras by the Grand Trunk Road. For many years it was a military station, and has a reputation for muslins. Pop. (1881) 16,355.

Chicago (pronounced *Shekahgo*) is situated in the north-east corner of the state of Illinois, about the fork and mouth of the Chicago River, on the west shore and near the head of Lake Michigan, in 41° 52' N. lat., and 87° 35' W. long. The city covers an area of nearly 37 sq. m., or 23,680 acres, which is divided into north, south, and west 'sides' by the river and its branches, and are connected with each other by thirty-three bridges, and two tunnels for vehicles and passengers. The river frontage, counting both sides, extends 41 miles.

Joliet and Marquette visited the place in 1673, and a rude church was erected by the latter in the following year. At a subsequent date the French, in extending their possessions to New Orleans, built a fort here, which was afterwards abandoned. In 1795 the Indians, who had been very troublesome, agreed to a treaty whereby they, among other things, ceded to the government 'one piece of land, six miles square, at the mouth of the Chekajo River, emptying into the south-west end of Lake Michigan, where a fort formerly stood; and near the mouth of the river 'Fort Dearborn' was built in 1804. The history of Chicago as a city dates from 1837, when it was incorporated, with a population within its limits of 4170. In 1840 the first census was taken, the inhabitants numbering 4479. In 1845, however, these figures were nearly trebled, the statistics showing 12,088. Since that

time the city has made prodigious strides in extent and in the acquisition of wealth. From a small trading village it has expanded into a great metropolis, ranking, in the United States, second only to New York. It is the largest grain market in the world; and more hogs are killed, and more pork, bacon, and lard shipped, than in and from any other two cities on the continent. Its rapid growth has continued, and the population was in 1888 estimated at 850,000.

The site on which to rear such a city was anything but enticing, the land in places being barely on a level with the lake; but thoroughfares were gradually raised from 8 to 12 feet, and the surrounding lots progressively filled in. Now Chicago has some of the finest streets (laid out with mathematical regularity; cf. map) in all America, notably Michigan Avenue and Drexel Boulevard, and its thoroughfares measure altogether 640 miles. There are four city railway companies, with 113 miles of track; considerable portions of the north and south side roads being worked by the cable-car system.

The dark shading shows the area of the great fire.

Among the public buildings of Chicago, many of them noted for their architectural beauty, are the new Board of Trade building, of granite, with a tower, rising 304 feet from the street level; the county court-house and city-hall, a structure of Silurian limestone and Maine granite, erected at a cost of nearly \$6,000,000; the criminal court and county gaol; the United States custom-house and post-office; the Art Institute building; the Dearborn Observatory; the Exposition Building, an immense structure on the lake front, frequently used for concerts and exhibitions; the Auditorium, a public hall, with a seating capacity of 7500; 20 theatres, and several music-halls; 34 hotels, some palatial in size and appointments; the Cook County Hospital, with accommodation for 800 patients; 6 other hospitals, and 25 orphan asylums and other benevolent institutions.

Chicago is also a city of church buildings, yet it contains fewer church-going people in proportion to its population than any other American city. All the places of amusement—theatres, concert halls, dime museums, summer gardens, &c.—are crowded with the working-classes on Sunday; and in the summer season the pleasure-steamers are loaded with excursionists. All Sunday laws

have been repealed, and the day is one of general festivity. Of churches there are about 290 of all denominations, many of them fine specimens of ecclesiastical architecture. The educational scheme of Chicago is excellent. Besides three high schools, there are ninety-five public schools where, in 1887, 84,902 pupils were enrolled, under 1574 teachers and principals; the total cost of the system for the year being \$2,020,738. There are also a large number of medical and commercial colleges, a university at Evanston, 12 miles to the north, with some 800 students, and several religious seminaries in the city and its suburbs; besides about 180 private schools of all denominations, with 46,000 pupils and over 1000 teachers. The public library, with 138,902 volumes, in 1888 ranked third in the United States; and in that year the Newberry Free Library, founded by a legacy of \$2,000,000, was in course of establishment. There are 15 daily newspapers published in Chicago, and about 200 magazines and periodicals.

The park system is without a parallel in America; it embraces Lincoln Park, on the lake shore to the north, and five others, and is divided into three sections, all connected or nearly so by magnificent boulevards, which, with the park drives, measure 58 miles. Among other open spaces are 20 large cemeteries, beautifully laid out, besides numerous smaller parks and squares, and three driving parks close to the city. The water-supply system is considered to be the finest of any in the country, with its 640 miles of pipe; a new tunnel, capable of furnishing 100,000,000 gallons a day, and running 4 miles out into Lake Michigan, was constructed in 1888.

The sewerage of the city is emptied, by a canal connecting the Chicago and Illinois rivers, into the Mississippi, and thence to the Gulf of Mexico; and the garbage is disposed of by fire, in a furnace specially constructed for the purpose, capable of consuming 150 tons a day. Of the large cities of the country, Chicago is one of the healthiest. The lowest death-rate was 15.70 in 1878, and the highest 23.60 in 1882. The rate of mortality for 1887 was 20.27.

The great secret of Chicago's phenomenal growth is its transportation facilities by rail and water. Fully one-third of the railroad system of the United States centres there, and, with its branches, comprises over 66,000 miles of permanent way. The amount of through tonnage forwarded *via* Chicago lines during 1887 was 3,257,315 tons. But the great waterway by Lake Michigan and its connections is unquestionably of most importance for the prosperity of the city. In 1887, 11,950 vessels, with a tonnage of 4,328,292, entered, and 12,023, with a tonnage of 4,421,560, cleared the port. Most of the lake-vessels, though they are often large and handsome craft, differ considerably in build and rig from sea-going vessels. In 1888 a steamer from London direct landed her cargo at this city. This was the first event of the kind, although sailing-vessels had previously cleared thence for European ports.

South-west of the city, and just beyond its limits, are the Union Stock-yards, established in 1866, the largest live-stock market in the world, occupying 345 acres of land, and costing upwards of \$3,000,000. The yard and pens cover 146 acres, with accommodation for 25,000 head of cattle, 150,000 head of hogs, 20,000 sheep, and stabling for 1000 horses. About 40 miles of railroad track are owned by the company, and these connect with every road centering in the city. The combined capacity of the packing-houses located at the yards is about 60,000 hogs per day. Another remarkable feature of the Chicago cattle trade is the 'dressed beef' business; and large orders for canned meats are also filled

here for the different European governments. The following table shows the general trade returns for 1887:

	Receipts.	Shipments.
Cattle.....	2,882,008	791,483
Sheep.....	1,360,862	445,094
Dressed hogs.....	13,508	140,747
Live hogs.....	5,470,852	1,812,001
Horses.....	46,404	
Cured meats, tons.....	106,834	333,941
Canned meats, cases.....	8,967	924,217
Dressed beef, tons.....	3,423	366,881
Beef, packages.....	2,397	128,455
Hides, tons.....	42,403	81,201
Wool, tons.....	13,164	14,619
Pork, barrels.....	76,155	335,720
Lard, tons.....	42,191	142,419
Cheese, tons.....	22,316	20,112
Butter, tons.....	51,500	51,001
Coal, tons.....	7,672,530	1,092,624
Lead, tons.....	25,000	
Lumber, m.....	1,860,060	920,417
Shingles, m.....	610,440	71,470
Salt, barrels.....	1,841,594	1,397,382
Potatoes, bushels.....	4,000,000	

Chicago is also the leading grain market of the world, and has unequalled facilities for handling, storing, and marketing this produce. There are 28 elevators, with a carrying capacity of 28,475,000 bushels. The receipts and shipments of grain, &c. for 1887 were as follows:

	Receipts.	Shipments.
Flour, barrels.....	6,572,327	6,302,598
Wheat, bushels.....	21,411,249	26,850,576
Corn, bushels.....	51,538,217	50,443,992
Oats, bushels.....	45,309,277	37,148,221
Rye, bushels.....	847,000	690,830
Barley, bushels.....	12,170,402	7,216,580
Total bread-stuffs, bushels.....	160,851,025	150,981,890
Grass-seeds, tons.....	30,547	31,215
Flax-seed, bushels.....	5,449,073	5,285,598

Across the lake lie the immense 'pineries' of the states of Michigan and Wisconsin, from whence the Chicago market is mainly supplied with lumber, the transactions in which exceed those of any other city. The estimated stocks on hand in the yards and planing-mills at the close of 1887 was 586,000,000 feet.

The manufactures of the city include nearly every conceivable variety of production, from a child's toy to the largest steam-engine. The number of establishments for 1887 is given as 2396; capital employed, \$113,900,000; employees, 134,615; wages paid, \$74,567,000, with the value of the whole product estimated at \$403,109,500. The wholesale trade of the city is of equally extensive proportions, the volume of business for 1887 being placed at \$449,000,000; the value of imported merchandise entered for consumption was \$13,145,563, and the duties collected thereon \$4,734,950.97. Chicago has 28 banks, with a total capital of about \$25,000,000; the bank clearings for 1887 amounted to \$2,969,216,210. The assessed valuation of real and personal property in the city for 1887 was \$161,204,535.

What is known as the great fire, which broke out on Sunday, October 7, 1871, devastated a total area, including streets, of nearly 3½ sq. m.; about 17,450 buildings were burned, 98,500 persons rendered homeless, and some 200 lives sacrificed, the total money loss being estimated at \$190,000,000. As a result of this disaster, when this central portion was rebuilt, brick, iron, and stone structures were erected, and stone pavements also were substituted for wood. Another conflagration, on July 14, 1874, destroyed about \$4,000,000 worth of property, including over 600 houses, mostly frame shanties. On the evening of May 4, 1886, occurred the 'Haymarket Massacre', in which eight policemen were killed and sixty maimed by a dynamite bomb thrown by an anarchist from among a crowd of labour agitators. For this crime four men were hanged, November 11, 1887, and three others

received various terms of imprisonment. Another anarchist plot was detected in July 1888. See Andreas' *History of Chicago* (Chicago, 1885).

Chicha. See STERCULIA.

Chichen, one of over fifty ruined towns in the Mexican province of Yucatan, a few miles WSW. of Valladolid, with the remains of an ancient Indian city, comprising a vast temple with bas-reliefs, a pyramid, houses containing sculptured chambers, &c.

Chichester, a municipal borough and episcopal city in Sussex, 17 miles ENE. of Portsmouth, and 28 W. of Brighton. It stands on a plain between an arm of the sea and the South Downs, which rise gently on the north. It is well built, and has wide streets. The two main streets cross at right angles, and meet in an elaborate eight-sided market-cross (*circa* 1500). Within the suburbs the city is surrounded by an ancient wall, $\frac{1}{2}$ mile in circuit, with some semicircular bastions, and now a promenade under the shade of elms. The cathedral, erected in the 12th and 13th centuries, on the site of a wooden one founded 1108, and burned 1114, measures 410 by 131 feet, with a spire 277 feet high (rebuilt 1865-66, after its fall in 1861), and a detached bell-tower or campanile, 120 feet, the only structure of the kind retained by an English cathedral. The aisles are double—a mode of construction elsewhere seen only in Manchester Cathedral and in some parish churches. The choir, lady chapel, and cloisters offer interesting features. The bishop's palace is supposed to have been erected on the site of a Roman villa. Chichester has twelve parish churches, a market-house, corn exchange, guildhall (formed out of the chapel of the Franciscan monastery), council-house, a theological college (1872), and several other educational establishments. The chief trade is in agricultural produce and live-stock. Wool-stapling, malting, brewing, and tanning are also carried on. Pop. (1851) 8662; (1881) 9652. From the time of Edward I. till 1867 Chichester returned two members, and till 1885 one. The port of Chichester, 2 miles to the south-west of the city, is situated on a deep inlet of the English Channel, of about 8 square miles, and is connected with Chichester by a canal. Chichester was the Roman *Regnum*, and has afforded Roman remains—as a mosaic pavement, coins, urns, and an inscription of the dedication of a temple to Neptune and Minerva. Chichester was taken and partly destroyed in 491 by the South Saxons. It was soon after rebuilt by Cissa, their king, and called Cissanceaster, or Cissa's Camp. It was for some time the capital of the kingdom of Sussex. The South Saxon see was removed by Stigand from Selsey to Chichester towards the close of the 11th century. Among its bishops have been Reginald Pecock, Lancelot Andrews, John Lake, and Simon Patrick. In December 1642 the royalists of Chichester surrendered to the parliamentarians after an eight days' siege, recaptured the city in the December of 1643, but had again to surrender to Waller a month later after a siege of seventeen days. Among the prisoners of war was the famous Chillingworth, who was allowed to die here, and lies buried in the cathedral. See works by Willis (1861), Stephens (1876), and Swainson (1880).

Chickadee (*Parus montanus* or *atricapillus*), a North American titmouse, of sober black and gray plumage, and lively active habit. It is fond of pine-trees, feeds on insect larvæ, has a hardy constitution, and remains through the winter. Its cheerful song is echoed in one of Emerson's poems. See TITMOUSE.

Chickahominy, a river of Virginia, which flows within 5 miles of Richmond, and enters the

James, after a south-easterly course of 90 miles. Four battles were fought near its banks in June 1862.

Chickamauga, a tributary of the Tennessee River, rising in Georgia, and flowing north-west into Tennessee, in which state the Confederate General Bragg defeated Rosecrans in a battle fought on the banks of the stream, September 19 and 20, 1863.

Chickaree is a name given to the red, pine, or Hudson Bay squirrel. See SQUIRREL.

Chickasaw, a tribe of Indians, allied to the Cherokees (q.v.), formerly occupying the northern parts of Alabama and Mississippi, but now settled in Indian Territory. They number about 6000.

Chicken-pox, a contagious febrile disease, chiefly of children, and bearing some resemblance to a very mild form of Smallpox (q.v.). Chicken-pox is distinguished by an eruption of vesicles or blebs, which rarely become pustular or yellow, and leave only a very slight incrustation, which falls off in a few days, leaving little or none of the marking or pitting which is such a prominent feature in smallpox. From its vesicular character it has been called the *crystal pock*. It has been argued that chicken-pox is, in fact, only smallpox modified by previous vaccination; but this opinion, though maintained on good authority, is not accepted by most medical men. It is a disease of little or no danger, the fever being often hardly perceptible, and never lasting long.

Chick Pea (*Cicer*), a genus of the vetch tribe of Leguminosæ. The common chick pea (*C. arvense*) is an annual, $1\frac{1}{2}$ to 2 feet high, of a stiff upright habit, covered with glandular hairs, with inflated pods containing a few angular and wrinkled peas. It is largely cultivated in southern Europe and in many parts of the East, and hence occurs frequently also as a weed in cornfields. It is also grown in Spanish America. Large quantities of the peas are exported from British India under the name of *gram*, now well known in commerce; but the name is extended to other East Indian kinds of pulse. The peas are used as food, either boiled or roasted, and are the most common *parched pulse* of the East. They are a notable article of Spanish and French cookery; while their importance in Roman times is evidenced by the phrase, *fricti ciceris emptor* ('buyer of roasted chick peas'), as a conversational equivalent for a poor fellow. Its cultivation extends as far as southern Germany; but in the climate of Britain it is found too tender to be profitable. The herbage affords fodder, and the seeds are one of the occasional substitutes for coffee. In summer weather drops exude from this plant, which, on drying, leave crystals of almost pure oxalic acid. The too free and prolonged use of chick peas as food is believed to be liable to become the cause of dangerous and obstinate forms of disease.

Chickweed (*Stellaria media*), one of the most common weeds of gardens and cultivated fields, is a species of Stitchwort (q.v.). It is a native of most parts of Europe and of Asia, appearing during the colder months even on the plains of India; an annual, with a weak procumbent stem and ovate leaves, very variable; some of the smaller varieties in dry sunny situations sometimes puzzling young botanists from having no petals or only five or three instead of ten stamens; but always characterised by having the stem curiously marked with a line of hairs, which at each pair of leaves changes from one side to another, and in four changes completes the circuit of the stem. The leaves of chickweed afford a fine instance of the *sleep of plants*, closing up on the young shoots

at night. Chickweed is a good substitute for spinach or greens, although generally little regarded except as a troublesome weed, or gathered only by the poor to make poultices, for which it is very useful, or for feeding cage-birds, which are very fond of its leaves and seeds. A number of species of a nearly allied genus, *Cerastium*, also bear the name of Chickweed, or Mouse-ear Chickweed, and the name is occasionally given to other plants, either botanically allied, or of somewhat similar appearance.

Chiclana, a pretty town of Andalusia, Spain, 12 miles SE. of Cadiz, with a notable bull-ring and vineyards. Its mineral baths are much frequented. Pop. 11,627.

Chiclazo, a town of Peru, 12 miles SE. of Lambayeque, is the centre of a valuable sugar district. Pop. 11,325.

Chicopee, a post-village of Hampden county, Massachusetts, on the east bank of the Connecticut River, 4 miles N. of Springfield, with manufactures of cottons, bronze cannon, cutlery, and locks. Pop. 5000; of the township, including the large manufacturing village of Chicopee Falls, (1885) 11,528.

Chicory, or **SUCCORY** (*Cichorium*), a genus of Compositæ (sub-order Ligulifloræ), with few species, all herbaceous perennials, with spreading branches and milky juice, natives of Europe and West Asia.

Chicory (*Cichorium Intybus*):
a, single flower; b, a separate floret.

The Common Chicory or Succory (*C. Intybus*) is wild in England and most parts of Europe, growing in waysides, borders of fields, &c. It has a long carrot-like root, externally of a dirty or brownish-yellow colour, and white within. The stem rises 1 to 3 feet, the leaves resembling those of the dandelion; the flower-heads are sessile, axillary, large (1 to 1½ inch), and beautiful,

generally blue, more rarely pink or white. Chicory is pretty extensively cultivated, both in England and on the continent of Europe, as also in California, for its roots, while its herbage is good food for cattle. The blanched leaves are sometimes used as a salad, and are readily procured in winter by placing the roots in a box with a little earth in a cellar. To this genus belongs also the Endive (q.v.).

Chicory has been used as a substitute for coffee, or to mix with coffee, for at least a century. The roots are pulled up, washed, cut into small pieces, and dried on a kiln, which leaves a shrivelled mass not more than one-fourth the weight of the original root. It is then roasted in heated iron cylinders, which are kept revolving as in coffee-roasting, during which it loses 25 to 30 per cent. of its weight, and evolves at the same time a disagreeable odour, resembling burned gingerbread. An improvement to the chicory during roasting is the addition of 2 lb. of lard or butter for every cwt. of chicory,

which communicates to it much of the lustre and general appearance of coffee. It is then hand-picked, to remove chips of wood, stones, &c., and is reduced to powder, and sold separately as *chicory powder*, or is added to ordinary ground-coffee, and is sold as a mixture. Chicory contains a good deal of sugar, but otherwise does not serve to supply the animal economy with any useful ingredient. It gives off a deep brown colour to water when an infusion is made, and hence its main use in coffee. Some people dislike the taste of chicory, and when largely used, it has a tendency to produce diarrhœa; but many people prefer to use coffee mixed with chicory owing partly to the taste it communicates, but mainly to the appearance of strength which it gives to the coffee. See ADULTERATION.

Chief, in Heraldry, an ordinary consisting of the upper part of the field cut off by a horizontal line. It is generally made to occupy one-third of the area of the shield. The expression 'in chief' means not on a chief, but that the charge is borne in the upper part of the shield.

In Chief.

Chief-justice. See JUSTICE (LORD CHIEF).

Chiem-See, a lake of Upper Bavaria, the largest in the country, lies about 40 miles SE. of Munich, at an elevation of 1650 feet above the sea, with a length of 12 miles, a breadth of 7, and a greatest depth of 512 feet. It has three islands; its surplus water is discharged by the Alz into the Inn. The lake is famous for its fish; and a small steamer plies on it, although the primitive dug-out canoes are still its characteristic craft.

Chieri, a town of Northern Italy, 12 miles SE. of Turin by rail, with some fine churches, and silk, cotton, and linen manufactures. Pop. 9494.

Chieti, an archiepiscopal city of Italy, beautifully situated on a hill near the Pescara, 69 miles E. of Aquila by rail, and only 8 from the Adriatic. It has a fine Gothic cathedral, a lyceum, and a theatre, and manufactures cloth and silk. Pop. (1881) 12,273. Chieti was built on the site of the ancient *Teate* of the Romans, many of the remains of which are still visible. In 1524 St Gaetano founded here the order of the Theatines.

Chiff-chaff (*Sylvia hippolais*), a small species of warbler, of very wide distribution. It is common in the south of Europe, and arrives in Britain in early spring as a summer visitor, but does not reach Scotland. Its general colour is brown; the under parts lighter. It is a very sprightly little bird; but its song consists merely of a frequent repetition of two notes resembling the syllables chiff-chaff. It is also called the Lesser Pettychaps. *Phylloscopus tristis* is sometimes called the Siberian Chiff-chaff. See WHITETHROAT.

Chigi, a princely Italian family, whose founder was Agostino Chigi (died 1512), of Siena, who in Rome became banker to the popes, and was noted for his pomp and encouragement of art. See CIGNONI'S *Agostino Chigi il Magnifico* (Rome, 1881).—A descendant, FABIO CHIGI, occupied the papal throne as Alexander VII. (1655-67).—FLAVIO CHIGI, born in 1810, was till 1848 in the papal guard, and then became Bishop of Mira in *partibus*, nuncio at Munich, and till 1873 at Paris, and died a cardinal, 15th February 1885. The head of the family is Prince of Campagnano and Duke of Ariccia, and is also hereditary marshal of the Conclave.

Chignecto Bay, an inlet at the head of the Bay of Fundy, in British North America. It separates Nova Scotia from New Brunswick, is 30 miles long and 8 broad, and has an isthmus of only

14 miles in width between it and Northumberland Strait, in the Gulf of St Lawrence.

Chignon (Fr., originally the 'nape of the neck'), a general term for the long back hair of women when gathered up and folded into a roll on the back of the head and neck. Padded and powdered, it was a common mode of the 18th century; in 1866 it reappeared, and with the generous assistance of false hair attained such ungraceful proportions as by 1875 brought about its dismissal.

Chigoe, or **JIGGER** (*Sarcophylla penetrans*), a genus of flea, somewhat smaller than the familiar Pulex, and without its jumping legs. It is an American pest, found for about 30 degrees on each side of the equator, but especially abundant in the West Indies and in the north of South America. It is found also in the West African coast region.

Chigoe (*Sarcophylla penetrans*):
a, male; b, gravid female.

One of its many names—the 'sand-flea'—indicates its favourite haunt among sand. It seems always to keep near the abodes of men. The males and immature females live like other fleas on chance bites, and relish of course the blood of animals as well as of man. It is the impregnated female which is the chief trouble. Like many other animals it seeks a safe and quiet breeding-place. This is found under the skin of animals, on the feet or under the toe-nails of man. There the minute creature swells up enormously, attaining under the pressure of the growing eggs the size of a pea. Respiratory communication with the outer world is kept up by an air-hole at the posterior end. In less than a week the eggs are ready to be liberated, for the larvæ are not parasitic. The mother-animal has meanwhile undergone a marked degeneration, the internal organs being much squeezed and atrophied by the growth of the ova. The entrance of the female chigoe is marked by a tingling and itching sensation, but if the development be allowed quietly to proceed no evil results seem to follow. Pressure and premature attempts to isolate the intruder may, however, lead to ulceration. Its evil effects seem to have been exaggerated. When the development of eggs has been completed, the entire animal with its progeny may be gently removed, and in this operation the West Indian negroes are experts. Washing with tobacco-juice is also resorted to, and the leaves are sometimes pressed on the feet as a preventive.

Chigwell, a village of Essex, on the border of Hainault Forest, 13 miles N.E. of London. Its 'Maypole Inn' is familiar to readers of *Barnaby Rudge*; and it has a grammar-school, founded by Samuel Harsnet, Archbishop of York, in 1629, and improved and enlarged since 1871 at a cost of £10,000. Penn was a pupil. Pop. of parish (1861) 2676; (1881) 5431.

Chihuahua, the largest state of Mexico, bounded on the N. and N.E. by New Mexico and Texas, has an area of 83,746 sq. m., and a pop. (1882) of 225,251. In the east is the *Bolson de Mapimi*, a vast desert of sand and alkali plains; in the south and west the surface is mountainous,

and there are numerous rivers. The state is better adapted for stock-raising than for agriculture; the fertile districts are mainly confined to the valleys and river-courses. Cotton is grown in the south. The silver-mines were for centuries among the richest in Mexico, and though many are now abandoned, mining is still the chief industry. The state is traversed by the Mexican Central Railway. —The capital, Chihuahua, 225 miles S. of El Paso by rail, rises like an oasis in the desert, among roses and orange-groves. It is well built, with broad, clean streets, an imposing cathedral (1717–89), a mint, and an aqueduct 3 miles long, and is the centre of considerable trade with Texas. Founded in 1691, it had in the 18th century 80,000 inhabitants. Pop. (1889) 12,116.

Chikislar, a small port in Russian Turkestan, on the eastern shore of the Caspian, north of the mouth of the Atrek.

Chilblains are localised inflammations of the skin which occur in cold weather, and affect the parts farthest from the centre of the circulation—viz. the hands and feet, more rarely the ears or nose. They are at first bright red, but as they disappear assume a purplish tinge. Sometimes they break and give rise to ulcers, which are slow to heal. They occur most frequently in young people, affect women more often than men, and are generally associated with weak health and a sluggish circulation. They are often extremely irritable and painful, especially when the affected part has been chilled, and is quickly warmed again. In their treatment, regard must be had to the general health; good feeding, exercise, and tonics should be prescribed. It is very important that tight shoes, gloves, garters, and bracelets should be avoided; and that the affected parts should be warmly covered when exposed to the open air. Locally, when the skin is whole, some stimulating agent answers best; tincture of iodine, spirit of camphor, or mustard applied moist and rubbed till it dries. If the skin be very tender, collodion painted over it is useful. Broken chilblains should be dressed with resin ointment or Peruvian balsam on lint.

Child. For various subjects connected with children, see BIRTH, FETUS, FOUNDLING, INFANT, MAN; for legal standing, see PARENT AND CHILD, INFANT, MINOR, PUPIL, GUARDIAN, INHERITANCE, TUTOR; and for child-stealing, see ABDUCTION.

Child, FRANCIS JAMES, the most learned of ballad editors, was born in Boston, Massachusetts, February 1, 1825. He graduated at Harvard in 1846, and was an instructor there for some time in the department of mathematics, and afterwards in that of rhetoric. After a year or two spent in Europe, he was in 1851 appointed to the chair of Rhetoric at Harvard, which he exchanged in 1876 for that of Anglo-Saxon and Early English Literature. His first work was *Four Old Plays* (1848); but more important were his annotated edition of *Spenser* (5 vols. Boston, 1855), and of the *English and Scottish Ballads* (8 vols. Boston, 1857–59), in a great American series of 'British Poets.' The latter was at once recognised as the best collection of English ballad poetry—a place which it will lose only on the completion of the great comparative collection by the same editor (already 5 parts, Boston, 1882–88). This may be accepted as the final work on its subject, as it contains all the versions and variants collected from all sources, while the introductions to each ballad are masterpieces of luminousness and learning. An *édition de luxe* in form, and singularly free from typographical and other errors, this work will continue to be indispensable to all serious students of

popular poetry. Professor Child also contributed some valuable notes to Hales and Furnivall's reprint of Bishop Percy's folio manuscript (1867-68). His invaluable 'Observations on the Language of Chaucer and Gower,' forming two papers in the *Memoirs of the American Academy*, and reprinted in part i. of Ellis's *Early English Pronunciation* (1869), reveal a marvellously intimate knowledge of Middle English grammar.

Child, SIR JOSIAH, writer on commerce, was born in 1630, the second son of a merchant of London. He himself made a fortune of £200,000 as a navy victualler at Portsmouth and a director of the East India Company. In 1678 he was made a baronet, and he died 22d June 1699. His principal work is *Brief Observations concerning Trade and the Interest of Money* (1668); a 3d edition (1690), much enlarged, is entitled *A New Discourse of Trade*, and has as an appendix, 'A small Treatise against Usury.' In this work he explains his plans for the relief and employment of the poor, including the substitution of districts or unions for parishes, and the compulsory transportation of paupers to the colonies.—His brother, **SIR JOHN CHILD**, was governor of Bombay, where he died, 4th February 1690.

Child (born FRANCIS), **LYDIA MARIA**, American author, born in Medford, Massachusetts, in 1802, published her first novel in 1821, and in 1828 married David Lee Child (1794-1874), a journalist, with whom she edited the *Anti-slavery Standard* in New York in 1843-44. She was a conspicuous champion of the slaves, for whom she published an *Appeal* in 1833; the principal of her numerous other works are novels, the best of them relating to early New England history, and an ambitious but inaccurate work on the history of religion (1855). She died 20th October 1880.

Childermas, or **HOLY INNOCENTS' DAY** (28th December), is observed by the Church of Rome with masses in commemoration of the children killed by Herod. It was long considered unlucky to marry or to begin any work on this day, and from Fenn's *Letters* we learn that the coronation of King Edward IV. was put off till the Monday, because the preceding Sunday was Childermas Day. Innocents' Day is also a red-letter festival of the Church of England.

Children, PREVENTION OF CRUELTY TO. Experience has proved that defenceless children, even within the range of our boasted civilisation, are not infrequently grossly maltreated by parents, their natural protectors, and that therefore special legislation is necessary to secure their proper treatment. To ameliorate the condition of children has therefore entered largely into the scope of modern legislation. The Factory Acts (q.v.), the Education Acts, the Reformatory and Industrial Schools Acts, the Criminal Law Amendment Act, and the Dangerous Performances Act are all evidence of this fact. The operations of the recently formed *Societies for the Prevention of Cruelty to Children* show in the strongest light the necessity for their action, though it is but a very few years since this special agency was introduced among us. The first societies of the kind were established in the United States. That in New York was the earliest, as it is the largest and most influential. Liverpool in 1883, and London in 1884, followed this example, and now, by means of other local societies, or of local aid committees affiliated to the London society, the work they have undertaken is rapidly spreading. The London Society has published the following statement of its work during the first four years of its existence—i.e. from October 1884 to March 1888 inclusive. Number of cases undertaken in each

successive year: 95, 147, 258, 284; total, 784. Total of convictions for cruelty: 9, 16, 29, 54; total, 108. Night's lodgings afforded to children brought to the society's shelter: 779, 1768, 2906, 3017; total, 8470. Meals given to the children sheltered: 2294, 5010, 8834, 7936; total, 24,074. All this has been accomplished with an income averaging for the four years under £1450 per annum. With all this, the need of additional legislation has become more and more urgent. A further improvement in the law of evidence is required. It has already been enacted that a child's simple statement, judged intrinsically true, can be received, though the age has not been reached for the understanding of an oath. But a wife cannot give evidence against her husband of his drunken midnight cruelty to their child which she alone has witnessed, though a mother's evidence is legally admissible if she is not married to her child's father. State protection should be as freely accorded to the lives and limbs of children as, through the Court of Chancery, it is afforded to their property. By the Dangerous Performances Act perilous actions may be prohibited, but there is no stated authority to put the law in operation. This benevolent work for children is indeed essentially a special work, and the police have not the sufficiency of time, resource, and special training which its full discharge requires. Municipal corporations should be empowered to regulate as in America what is called 'street peddling,' as of evening newspapers and the like. The hours, varying with the season of the year, in which it may be carried on at all, and the ages of the boys and girls who may be engaged in it, should be fixed and enforced. Once give the necessary powers, and many present evils will cease.—For the Criminal Law Amendment Act, see ABDUCTION.

Childs, GEORGE WILLIAM, born in Baltimore, Maryland, 12th May 1829, became clerk in a bookstore in Philadelphia, and by 1850 was already head of a publishing firm, which soon became famous. In 1864 he became proprietor of the *Public Ledger* newspaper. He is distinguished for beneficence. He it was who placed a memorial window in Westminster Abbey to Cowper and George Herbert, and erected a monument to Leigh Hunt at Kensal Green.

Chili (written CHILE by its own citizens), one of the republics of South America. It is situated on the west coast, and may be described as a long strip of territory lying between the summit of the Andes and the Pacific Ocean, extending from about the 18th parallel of south latitude to the southern extremity of Tierra del Fuego. Boundaries: N. by Peru, E. by Bolivia and Argentine Republic, W. and S. by the Pacific Ocean. By recent treaties the territory of Chili has been considerably extended. After the war with Bolivia and Peru (1879-81), Chili acquired the coast between 23° and 25° S. claimed by Bolivia, and annexed the Peruvian province of Tarapacá. She also occupies the Peruvian provinces of Arica and Tacna, subject to the payment of a war-indemnity by Peru. In the south the disputed claims of Chili and Argentina to Patagonia have been settled by Chili taking all territory and islands south of the 52d parallel and west of 68° 30' W. This includes the larger portion of Tierra del Fuego. The Strait of Magellan is by treaty considered neutral. The length of Chili is about 2500 English miles. Its breadth varies from 40 to 200 miles. The Andes extend in two parallel lines throughout nearly the entire length of the country. Between these two ranges of the 'Cordillera' there is a central valley or tableland which attains its greatest breadth between 33° and

40° S. The streams in the north are of little importance, being mostly shallow brooks, which, after a short course, are licked up by the thirsty land; in the south they are larger and more numerous, although most are navigable for only a few miles. The principal are the Maipo, which waters the valley of Santiago; the Máuile; the Biobio (q.v.), the largest river in the country; the Cauten, or Rio Imperial; the Bueno; and the Callecalle, or Rio de Valdivia (100 miles), the most important of all, because of the sheltered harbour at its mouth. In the south are also many deep lakes, such as Llanquihue (30 miles long by 22 broad) and Ranco (32 miles by 18). Mineral waters, chiefly saline and sulphureous, are abundant; the principal spa is at Chillan (q.v.). The most important islands are those constituting the province of Chiloé (q.v.); Juan Fernandez (q.v.) also belongs to Chili. Owing to its great extension from north to south, Chili comprises regions of very different nature and climate. The north provinces, Tarapacá, Atacama, and part of Coquimbo are arid, rainless districts, where the principal industry is mining and extraction of saltpetre. The middle and southern provinces—viz. Aconcagua, Valparaiso, Santiago, Colchagua, Curicó, Talca, Linares, Máuile, Nuble, Concepcion, Arauco, Biobio, and Valdivia, are agricultural and viticultural, and have also valuable coalfields. The Patagonian region is densely wooded and sparsely inhabited by a few Indians. The climate of Chili is temperate. In the north it is moderately hot and rainless, but banks of clouds always hang overhead, and heavy dew falls at night. In the south it is dry for about eight months of the year, and rainy the other four. The temperature is remarkably even and pleasant, and always cool at nights. The south wind blows fiercely during many days of summer dry and cold; the north wind brings heat, tempest, and rain; other winds are unknown. In Southern Chili generally the land is poor and of hardly any value for agriculture, which, indeed, is carried on in a very primitive fashion; but the soil of the valleys, where large herds of cattle graze, is very fertile. Vines, also, grow well on the hillsides, and the wines of the country are superseding in Chili the French red wines. The Andes are almost everywhere visible, covered with perpetual snow. The highest peak is Aconcagua, 22,867 feet. The average height of the great range is 8000 feet. There are many volcanic peaks, mostly extinct. Amongst these may be mentioned Tupungato, Descabezada, Chillan, Osorno, Villa Rica, &c. Chili is subject to frequent shocks of earthquake, and occasionally to destructive *terremotos*. The most notable of these recorded was in 1822, when the coast near Valparaiso was thrown up permanently between 3 and 4 feet: this elevation extended over 100,000 sq. m. In 1835 Concepcion and Talcahuano were destroyed by a fearful earthquake which produced disaster all over the southern provinces. In 1868 Iquique was destroyed by a shock which was felt more in the northern districts, and again in 1875.

The population of Chili according to the census of 1885 was 2,524,476. After making allowance for the new territories acquired, it is computed that this is an increase of 352,813 since the preceding census of 1875, or about 17 per cent. The number of foreign residents increased from 26,635 to 40,000 during that period. The natives of Chili are a mixture of Spanish with the Araucanian Indians. In the upper classes the race has been kept more purely Spanish than in any other South American country. The working-classes are laborious and docile, but it cannot be said that there is as yet any effectual protection for property. Wages are still very low. On estates labourers receive about

1s. 6d. per day, but are allowed a patch of land to cultivate for themselves. Since the acquisition of the territory of the Araucanian Indians in 1881 the government has been anxious to attract European emigrants, but British adventure in that direction has been deprecated. There is practically no demand for English mechanics, and the manufactures, properly so called, are confined to copper-smelting, sugar-refining, tanning, brewing, manufactures of soap and candles, biscuits, boots and shoes, woollens, flax, and nitrates. A special effort is being made to introduce new manufacturing industries which will be protected by tariff.

The established religion of Chili is Roman Catholic, but public opinion is now very liberal, and other religions are tolerated. Education receives much attention. By statistics of 1886 there were 862 state schools, with a staff of 1232 teachers, having 78,810 scholars on the books; there were also 532 private schools, with 27,860 scholars. In 1887 the state schools had increased by 88, and the pupils by 2552. Government proposed in 1888 to spend \$3,500,000 in the erection of additional school-houses. There is a first-class university at Santiago, and a lyceum in every provincial capital. The language spoken in Chili is Spanish, but with many local words of Indian origin.

The value of imports in 1887 was \$48,630,862, and of exports \$59,549,958; a third of the imports and two-thirds of the exports were British, the German and French trade being next in importance. Mineral products represented five-sixths of the total exports. The chief articles of export were nitrate and iodine, copper, silver, gold, manganese, hides, wool, wheat, and barley. The principal imports were cotton, woollen, and jute goods, iron, hardware, coal, machinery, timber, rice, sugar, earthenware, cement, paper, beer, glassware, kerosene, tallow, matches, tea and coffee.

The railway system of Chili is well developed. A government broad-gauge line runs from Valparaiso to Santiago, crossing the coast-range of the Andes, and thence southwards through the central valley to Concepcion, and through Araucania towards Valdivia, making a total length of about 1500 miles. A branch from the Valparaiso and Santiago line also runs to Santa Rosa at the foot of the Andes, from which a line is now in progress, to unite with the Argentine railway system, *via* the Uspallata Pass, which it will cross at the elevation of 9843 feet above sea-level by means of a tunnel 6½ miles in length. When this is finished there will be a through communication from the Pacific to the Atlantic Oceans, and by many it is argued that this will be the shortest route from England to the Australian colonies. The length of the railway from Valparaiso to Buenos Ayres will be 880 miles. In the northern provinces there are several mineral railways belonging to English companies. One of these, the Antofagasta, is now being prolonged to Bolivia.

The financial position of Chili is satisfactory, and its credit stands higher than that of any other South American state, as is proved by the fact that it has been able to borrow money in the London market at the rate of 4½ per cent. per annum. At the end of 1887 the foreign debt amounted to about \$40,100,000, and the internal debt, including forced paper currency in circulation, to \$48,335,071. The revenue for 1888 was stated at \$39,000,000, and the expenditure \$39,615,770, but in this was included a large number of extraordinary expenses, so that in reality there would be, as in several preceding years, a considerable surplus. An idea of the progress of the country may be formed from the fact that the customs revenue, which in 1856 amounted to \$4,147,298, in

1866 to \$3,053,416, and in 1876 to \$7,422,791, in 1886 reached \$23,416,346. The current money of Chili previous to the late war was gold and silver and a restricted bank-note issue which stood at par. The necessities of the government caused an issue of inconvertible paper notes which subsequently fell to a serious depreciation. The par value of a dollar is equal to 5 francs or a little over 48d., but its value in exchange during the war with Peru was as low as 16d. Its value in 1888 was about 26d. Owing to this circumstance it is difficult to form an exact estimate in sterling of the exports and imports. Elaborate statistics are regularly published by the government. The values are arrived at by official valuation, which is not always in proportion to the real value. Government accounts are also still kept as though the dollar was equivalent to 48d. The foregoing statistics must therefore be modified in view of those conditions.

The constitution of Chili is republican and based upon that of the United States. Every citizen is entitled to a vote who can read and write and prove that he earns \$150 or upwards a year, and is twenty-one years of age if married, or twenty-five if single. The president is appointed by a body of electors chosen by the people. His term of office is five years, and his salary \$18,000 per annum. The cabinet consists of six ministers—viz. of Finance, the Interior, Foreign Affairs, War, Commerce and Public Works, and of Justice, Public Worship, and Instruction. The Council of State consists of five members nominated by the president, and six appointed by congress. The legislature is composed of two chambers—viz. the Deputies, about 100 in number, being in proportion of one to 20,000 inhabitants; and the Senate, numbering one to every five deputies. Deputies must have an income of at least \$500, and senators of \$2000. The elections are conducted with considerable fairness, but as the majority of the representatives chosen have come from the ranks of a few leading families, Chili has been well described as 'an aristocratic republic.' This state of affairs, however, has brought excellent results, as the Chilean government has long had a deservedly high reputation for ability and integrity.

History.—The name Chili is supposed to be derived from an ancient Peruvian word signifying 'snow.' The northern portion, as far as the river Maule, formed part of the dominions of the Incas of Peru. The southern was held by the valiant Araucanians, the only aboriginal race which was not subdued by the Spaniards, and which until a few years ago maintained their independence against the Chileans. The first European to land in Chili was the Portuguese discoverer Magellan, after his famous voyage through the strait which now bears his name. He landed at Chiloé in 1520. After the conquest of Peru by Pizarro, an expedition was made to Chili from that country overland under the leadership of Diego de Almagro in 1535. This expedition penetrated as far as the Rio Clano, but returned unsuccessful. Another was sent under command of Pedro Valdivia in 1540, which succeeded in annexing the territory as far as the river Maipo. Santiago, the capital, was founded by Valdivia in 1542. During the colonial period the governors of Chili were appointed by the viceroys of Peru. In 1810 a revolt against the Spanish power broke out, in which Don Bernardo O'Higgins, son of one of the last viceroys of Peru, but a native of Chili, played a conspicuous part, and finally became the first dictator of the new republic. The conflict between the Spanish troops and the republican army continued until 1826, when peace was definitely settled, and Chili left to govern itself. The first constitutional

president was General Blanco Encalada. The government was unsettled until 1847. A revolution broke out in 1851, but since then there has been no serious attempt to overturn the government by force of arms. In 1864 Chili gave Peru very valuable support in her war with Spain. Valparaiso was bombarded by the Spaniards in 1866. In 1879 Chili declared war against Bolivia, and immediately thereafter against Peru, with which Bolivia was allied. For a time the Peruvian fleet kept the Chileans in check, but in August 1879 the Peruvian ironclad *Huascar* was captured by the Chilean men-of-war *Cochrane* and *Blanco Encalada*, both armour-plated. After this event the success of the Chileans was uninterrupted. Peruvian towns were bombarded, and their other war-ships captured. Finally Lima was taken by storm on 21st June 1881. The Chileans occupied Lima and Callao until October 30, 1883, when a treaty of peace was signed. By this a portion of Peruvian territory (see above) was ceded to Chili.

See Sir Horace Rumbold, *Le Chili* (Paris, 1877); Robiano, *Chili* (Paris, 1882); Ochsensius, *Chile, Land und Leute* (Leip. 1884); Boyd, *Chili and the Chileans during the War* (1881); Clements R. Markham, *The War between Chili and Peru* (1883); Lord Cochrane, *Concerning Chili*, in the *Fortnightly Review* (1884); the *Historia General* by Arana (Valparaiso, 4 vols. 1863), and that by Rosales (1878).

Chiliasm. See MILLENNIUM.

Chili Nettle. See LOASACEÆ.

Chillán, capital of the Chilean province of Nuble (area, 3556 sq. m.; pop. in 1885, 149,871), was formerly an important centre of the Jesuit missions, but is now only of interest for its commercial activity. Close by, however, romantically situated on the slope of the extinct volcano of Chillán (9445 feet), are the *Baños de Chillán*, with bathing establishments, which are in high repute among persons suffering from gout, rheumatism, dyspepsia, and cutaneous diseases. Pop. of Chillán, 16,000.

Chillesford Beds. See PLIOCENE.

Chilli. See CAPSICUM.

Chillianwalla, a village of the Punjab, 5 miles from the east bank of the Jhelum, and 85 miles NW. of Lahore. It was the scene of an indecisive but sanguinary battle during the second Sikh war, 13th January 1849, and is the site of an obelisk erected to the memory of the British officers and men who fell in the engagement.

Chillico'thé, capital of Ross county, Ohio, pleasantly situated on the Scioto River and on the Ohio Canal, 50 miles S. of Columbus by rail. It has manufactures of paper, leather, farming implements, &c., and was from 1800 to 1810 the capital of the state. Pop. (1880) 10,938.

Chillingham, a village in the north of Northumberland, on the river Till, 8 miles SW. of Belford. To the south is Chillingham Castle, seat of the Earl of Tankerville, built in the reign of Edward III. In the park, as at Cadzow, are preserved a herd of wild white cattle. See CATTLE.

Chillingworth, WILLIAM, one of the greatest of English controversial theologians, was born at Oxford in 1602, the son of a prosperous citizen, who afterwards became mayor. Laud, then Fellow of St John's College, was his godfather. In 1618 he became a scholar of Trinity College, and in 1628 was elected to a fellowship in his college. Aubrey's story that he acted here as a kind of spy for Laud rests on Sir William Davenant's dubious authority alone, and may safely be neglected. His great parts soon secured him the intimacy of Sir Lucius Carey, afterwards Lord Falkland, John Hales of Eton, and Gilbert Sheldon, afterwards Archbishop of Canterbury;

and his restless intellect soon turned to the question of chief interest at that time in his university—the controversy between the Church of England and the mother Church of Rome. The arguments of an able Jesuit, known by the name of John Fisher, at length convincing him of the necessity of an infallible living judge in matters of faith, he embraced the Romish communion 'with an incredible satisfaction of mind.' In 1630 he went to Douay, and here being urged to write an account of the motives of his conversion, a fresh examination of the whole questions at issue, and a series of letters from Laud, at length brought him from doubt of the soundness of his recent conclusions to a complete renunciation. But although he had become convinced that the claims of the Church of Rome to an infallible judgment on matters of faith had no real foundation, he adhered alone to Scripture as interpreted by the light of reason, and for a time declined to take orders in the Church of England, regarding her Articles as themselves a needless 'imposition on men's consciences.' Meantime he had become involved in a succession of controversies with John Lewgar, a Catholic convert; Floys, a Jesuit, who went under the name of Daniel; and White, the author of *Rushworth's Dialogues*. His papers in answer to these—mere preliminary studies for the great work that was to follow—are contained in his *Additional Discourses*, published in 1687. Another Jesuit, known as Edward Knott, having published in 1630 his *Charity Mistaken, &c.*, which was answered by Dr Christopher Potter, provost of Queen's College in Oxford in 1633, rejoined in 1634 with *Mercy and Truth, &c.* This second book Chillingworth undertook to answer, and with that view retired to the quiet of Lord Falkland's house and library at Great Tew in Oxfordshire. Meantime, Knott hearing of his intention, hastened to take an unfair advantage of his antagonist, by an attempt to pre-judge the public mind beforehand. In 1636 he issued in a forty-two page pamphlet a series of mere scurrilous insinuations, the main drift of which was that Chillingworth was a Socinian, whose opinions tended to the overthrow of all supernatural religion no less than of Catholic doctrine. At length, in 1637, appeared Chillingworth's famous book, *The Religion of Protestants a safe Way to Salvation: or an Answer to a Booke entitled Mercy and Truth, &c.* This great work suffers from its being necessarily to some extent an answer to a now completely forgotten book, and being thereby weighted with a great mass of extraneous matter. Indeed, it is only after the author has demolished the arguments of his temporary antagonist that he is at liberty to follow the unembarrassed course of his own thought, and it is evident that only a writer of consummate talent could so have surmounted the disadvantages of such a form, as to make a book of enduring interest and value. Yet it is all this and more, for we have here not only a masterly demonstration of the sole authority of the Bible in the essential matters relating to salvation, but an assertion of the free right of the individual conscience to interpret it, laid down once for all with perfect confidence and fullest plainness—the freedom of religious opinion and the right to toleration for honest difference of opinion placed on its true basis, and this two centuries and a half ago. The great question at issue is that of the basis of religious certitude, or 'the means whereby the truths of revelation are conveyed to our understanding,' whether this is to rest on the infallible authority of the Church, or ultimately on the authority of the Scriptures alone.

Here Chillingworth's conclusion is, in his own oft-quoted words: 'The Bible, I say, the Bible

only, is the religion of Protestants.' The great principles of religion, and everything of faith essential to salvation, are herein clearly revealed patent to the 'right reason' and judgment of every man. Religious certitude can thus be reached by every honest mind, from the plain interpretation of the Bible, which is necessarily itself intelligible and sufficient, without need of any medium to transfer it or judge to interpret it. Indeed, the measure of the responsibility of faith is just the measure of the clearness and simplicity of the divine revelation. Scripture and the candid mind acting together, under the quickening grace of God and the guidance of the Holy Spirit, are thus the sole factors of religious certitude, which is necessarily based on rational personal conviction. The simplest creed is the best creed, and the only possible basis on which to reconstruct the divided church is such a 'simple, assured, and accepted religious minimum as the apostles' creed, with full freedom to individual opinion in everything supplementary and unessential. 'For why,' he asks, 'should men be more rigid than God? Why should any error exclude any man from the Church's communion, which will not deprive him of eternal salvation?' It may be that Chillingworth's ideas carried out would have made any kind of church polity or even successive organised religious life impossible, but at least they would have preserved something perhaps quite as precious—an intellectual conception of toleration, that would have saved England years of misery and blood; and which need not necessarily have eliminated also the religious enthusiasm of the individual, together with his confidence in the absolute infallibility of his own opinions.

The reasoning throughout the great work of Chillingworth is marked by strong and clear intellect; singularly simple but direct and straightforward style, warming at times into a suppressed but vehement eloquence, and informed throughout with an honesty, an earnestness, and, above all, a fairness but rare in controversial literature. Locke, in his *Thoughts concerning Reading and Study for a Gentleman*, commends 'the constant reading of Chillingworth, who, by his example, will teach both perspicuity and the way of right reasoning better than any book I know.' Chillingworth left little besides his masterpiece—nine sermons, the 'Additional Discourses' already referred to, and a brief fragment on the apostolical institution of episcopacy forming the whole. The rest of his life is soon told. At length he found himself able to give a general assent to the Articles, and in July 1638 he was made Chancellor of Salisbury, with the prebend of Brixworth in Notts annexed, and soon after master of Wigstan's Hospital in Leicester. In 1640 he was elected proctor to convocation by the Chapter of Salisbury. At the outbreak of the Civil War he accompanied the king's forces, though his heart sank within him to see 'publicans and sinners on the one side, against scribes and Pharisees on the other.' He was with the royal army before Gloucester, where, we are told, he devised an engine for purposes of assault after the pattern of the old Roman *testudo*. At Arundel Castle he was taken ill, and when the garrison surrendered to Waller, being too ill to be carried to London, was lodged in the bishop's palace at Chichester, where he died, 30th January 1643. His last hours were pestered by the ill-timed and cruel exhortations of one Cheynell, an ignorant and rabid Puritan preacher, who, at his burial in Chichester Cathedral, flung a copy of the noblest theological treatise of the age into the grave, that it might 'rot with its author and see corruption.' The *Chillingworthi Novissima, &c.* (1644), in which this Westminster divine did such dishonour to

himself, is one of the most melancholy monuments that exist of fanatical and unchristian bigotry. It was Chillingworth's fate to be assailed with 'great asperity and reproaches' all his life, and throughout to be misunderstood by blind Papist and blind Puritan alike.

See the *Life* by Des Maizeaux (1725), and that by Rev. Thomas Birch, prefixed to his edition of the works (1742). Of these the best edition is that published at Oxford in 3 vols. in 1838. See chapter v. (vol. i.) of the late Principal Tulloch's *Rational Theology in England in the Seventeenth Century* (2 vols. 1872).

Chillon, a celebrated castle of Switzerland, at the eastern end of the Lake of Geneva, $1\frac{1}{2}$ mile SSE. of Montreux. It stands on an isolated rock, 22 yards from the shore, and connected therewith by a bridge, though the strait between them is dry. Dating perhaps from the 8th century, it seems to have been partly rebuilt in 1238, by Amadeus IV. of Savoy, and it long served as a state prison. Here for six years (1530-36) Bonivard (q.v.) endured the captivity immortalised by Byron's *Prisoner of Chillon* (1821). Among the thousands of names inscribed on the pillars of the dungeon are those of Byron, Georges Sand, and Victor Hugo. The castle is now used as a magazine for military stores.

Chiloé, the insular province of Chili, consists of the island of that name on the west coast, which is separated from the mainland by a narrow strait on the N., and by a gulf 30 miles wide on the E., and has a length of 115 miles, and an extreme breadth of 43 miles, and of a number of neighbouring islets, mostly uninhabited; total area, 3980 sq. m.; pop. (1885) 73,420, almost all Indians living on the principal island. Chiloé proper is hilly in the interior, and everywhere covered, except immediately along the shores, with nearly impassable forest. The climate is mild and not unhealthy, although inordinately wet. The Indians belong to a subdivision of the Araucanian family; they are a gentle and honest race, mostly engaged in fishing and in lumbering, timber being at present the chief export from the island, although immense deposits of coal have been reported. The capital, Ancud, on the north coast, has a good harbour, but is meanly built; it is the seat of a bishop, and has a population of 6000.

Chilog'natha, **Chilop'oda**. See MYRIPODA.

Chiltern Hills, the southern part of the low chalk range which runs north-east, about 70 miles, from the north bend of the Thames, in Oxfordshire, through Bucks and the borders of Herts and Beds. In Oxford, Herts, and Beds the Chiltern Hills are 15 to 20 miles broad, and the highest point is near Wendover (950 feet). In his sketch of John Hampden's home, Mr Green paints finely 'the quiet undulations of the chalk country, billowy heavings and sinkings as of some primeval sea suddenly hushed into motionlessness, soft slopes of gray grass or brown-red corn falling gently to dry bottoms, woodland flung here and there in masses over the hills. A country of fine and lucid air, of far shadowy distances, of hollows tenderly veiled by mist, graceful everywhere with a flowing unaccentuated grace, as though Hampden's own temper had grown out of it.'

Chiltern Hundreds. In former times the beech-forests which covered the Chiltern Hills were infested with robbers, and in order to restrain them it was usual for the crown to appoint an officer, who was called the Steward of the Chiltern Hundreds. The hundreds in question (see HUNDRED) are those of Bodenham, Desborough, and Stoke, in Buckinghamshire. The stewardship, which has long ceased to serve its primary purpose,

now serves a secondary one. A member of the House of Commons cannot resign his seat unless disqualified either by the acceptance of a place of honour and profit under the crown, or by some other cause. Now, the stewardship of the Chiltern Hundreds is held to be such a place, and it is consequently applied for by, and granted, usually as a matter of course, to any member who wishes to resign, though it has been refused in a case of bribery. As soon as it is obtained, it is again resigned, and is thus generally vacant when required for the purpose in question. When the Chiltern Hundreds are not vacant, however, the same purpose is served by the stewardship of the manors of East Hendred, Northshead, and Hempholme. The practice of granting the Chiltern Hundreds for the purpose above described began only about the year 1750; the gift lies with the Chancellor of the Exchequer.

Chimæra, a fire-breathing monster, described by Homer as having a lion's head, a goat's body, and the tail of a dragon. In Hesiod's account a daughter of Typhaon and Echidna, she devastated Lycia until killed by Bellerophon. Gigantic carvings of the chimæra on rocks have been found in Asia Minor, representing the monster as a lion, out of the back of which grows the neck and head of a goat. It is frequently depicted on shields as a heraldic charge. The name is used figuratively as a word denoting any monstrous or impossible conception, the unnatural birth of the fancy—Tennyson's '*chimæras*, crotchets, Christmas solecisms.'

Chimæra, a genus of cartilaginous fishes, and type of a distinct order, Holocephali, which is often ranked along with the sharks and rays, or Elasmobranchs. The chief distinctions are the presence of a fold of skin covering the (4) gill-clefts, the nakedness of the skin, the fusion of the upper jaw to the skull, the separation of anal, urinary, and genital apertures. There are no 'spiracles,' nor 'spiral-valve.' Except in the above particulars, and a few others of a more technical nature, the members of this small order agree with the ordinary Cartilaginous Fishes (q.v.). There are only two living genera—*Chimæra* and *Callorhynchus*. The best-known species of chimæra (*C. monstrosa*) is often called the King of the Herrings, and is occasionally taken in herring-nets in British seas.

Chimæra monstrosa.

It is found on the coasts of Europe and Japan, in North Atlantic, and at the Cape of Good Hope. In the United States it is called Sea Cat. It is an ugly fish, seldom over 3 feet in length, of a whitish colour, spotted with brown above. The males have claspings organs; the large eggs are inclosed in a leathery case. The *C. Collieri* is found on the west coast of North America; and the *C. Affinis* on the coast of Portugal. In the other genus, *Callorhynchus*, in the South Pacific, the snout bears an appendage, and the tail is not symmetrical as in the above, but slightly shark-like.

Chimaphila. See WINTER-GREEN.

Chimbora'zo, a conical peak of the Andes, in Ecuador, 20,517 feet above the sea, but only about 11,000 above the level of the valley of Quito, to the north. The 'silver bell' of perpetual snow and glacier was long erroneously regarded as the loftiest mountain not only in America but in the whole world. From 1745, when La Condamine ascended as high as 16,730 feet, numerous only partially successful attempts had been made to scale the mountain before Whymper in 1880 twice reached the summit.—The peak gives name to the province of Chimborazo, to the south, with an area of 5523 sq. m., and a pop. (1885) of 90,782, exclusive of the uncivilised Indians.

Chimere, a bishop's upper robe, to which the lawn-sleeves are attached. That of Anglican bishops is of black satin, that of English Roman Catholics is of purple silk.

Chimes. See BELL.

Chimney, a flue constructed in the thickness of a wall or in a separate 'stalk' for the purpose of carrying off the smoke from a fireplace or furnace. The heated air being lighter than the atmosphere which maintains the fire, presses the smoke upwards, and rises with a rapidity proportioned to the difference in weight, assuming that the chimney is of proper construction and size. It has been found in practice that a diameter of from 9 inches to 12 inches is suitable for the fireplaces of ordinary rooms, but in the case of kitchens and other large fires a greater width is required. In olden times it was usual to build fireplaces of great size, with very large chimneys, but as these admit a great quantity of air at the ordinary temperature, the draught is thereby checked, and the chimneys are apt to smoke. Experience has taught that the 'throat' or entrance to the chimney from the fireplace should be made as small as possible compatible with its task of carrying off the products of combustion from the fire. A proper draught depends also on the height of the chimney, which ought to be sufficient to be above the interference of swirls of air caused by surrounding buildings or other objects. The higher the chimney, the greater the draught.

Chimneys are of comparatively modern origin. Only traces of them are found in classic antiquity; but there must have been some such means of discharging the smoke from the fires which heated the hypocausts of the Roman baths. In medieval times, the earliest examples of fireplaces with chimneys, such as those in the Norman castles of Rochester and Castle Hedingham, erected in the 12th century, have only a short flue ascending a few feet, and discharging by an oblong aperture in the outer face

of the wall. These were no doubt found very smoky and inconvenient, and ultimately the chimneys were carried to the roof. In Gothic buildings they are often detached, and the outlet is ornamented with trefoil and other openings. In the English halls the centre hearth was long retained, without any chimney, the smoke being allowed to find its way out through an opening in the roof called the Louvre (q.v.). In Scottish mansions and castles the fireplace was an invariable feature in every apartment from the 13th century. The hall has always a large fire-

bedrooms are smaller. In the late Gothic and Elizabethan styles the chimneys are amongst the most striking features of the design, being carried up in lofty and highly ornamented stalks, frequently built in brick.

In modern times the external appearance of chimneys has been greatly neglected, to the sad disfigurement of our houses, but a better taste is now beginning to prevail. In

one direction, however, modern chimneys have received a great development in connection with furnaces and steam-engines. In order to create a draught, and so cause the fire to burn with intense heat, these chimney-stalks are carried to a great height. The difference of pressure of the atmosphere between the top and bottom, added to the lightness of the air caused by the heat, acts as the motive power to the 'draught,' which thus increases with the height of the stalk. Amongst the highest existing chimneys may be mentioned the following: (1) the Townsend shaft, Port Dundas, Glasgow, which is 468 feet in total height, and has a diameter of 32 feet at base, and 13 feet 4 inches at top; weight, about 8000 tons. (2) St Rollox shaft, Glasgow—total height, 455 feet 6 inches; diameter at base, 50 feet; at top, 13 feet 6 inches.

(3) Mechernich shaft, Cologne—total height, 441 feet; diameter (square) at base, 39 feet; at top (round), 11 feet 6 inches; weight, about 5459 tons.

An act to regulate chimney-sweeping was passed as early as 1789; and in 1842, to prevent the fearful cruelties practised on young chimney-sweepers, it was rendered penal to compel or knowingly allow any person under the age of twenty-one, to ascend or descend a chimney or enter a flue for the purpose of cleaning or curing it; and no child under sixteen could be thereafter apprenticed to the trade. The act was extended and made more stringent in 1864 and 1875.

To extinguish a chimney on fire, it is only necessary to hang over the fireplace a piece of wet carpet or blanket: some handfuls of salt thrown into the fire at the same time will greatly aid the extinction. It is also recommended to scatter a handful of flowers of sulphur over the duller part of the burning coals, the vapour arising from which will not support combustion, and will consequently extinguish the flames. Throwing water down from the top is a clumsy expedient, by which much damage is frequently done to furniture; so also is stopping at the top, by which the smoke and suffocating smell of the burning soot are driven into the apartment. If every fireplace were provided with a damper, or shutter of sheet-iron, sufficiently large to choke it thoroughly, fire in chimneys would become of little consequence, as it would only be necessary to apply this damper to extinguish them. All good modern grates are furnished with such dampers. To set chimneys on fire with a view to clean them is highly objectionable, even where there is no danger of fire to be apprehended, as the intense heat produced rends and weakens the walls. For other connected subjects, see SMOKE-NUISANCE, VENTILATION, WARMING.

Chimpanzee (*Troglodytes niger*), one of the highest of the anthropoid or more manlike apes,

Chimney, Thornbury Castle, Gloucestershire, 1514.

(From Parker.)

Chimney, Tisbury, Wilts.

(From Parker's Glossary.)

place and capacious

chimney, while those of the

belonging to the same genus as the gorilla (*T. gorilla*).

History.—The first historical notice of the chimpanzee seems to be that given in an account of a Carthaginian exploration of the north-west of Africa, conducted by Hanno in 470 B.C. Along with other anthropoid apes, it was known to the Romans in their varied communications with Africa. The first thorough investigation of the anatomy was made by Tyson in 1699. Various travellers gradually gathered information in regard to its habits, and captured specimens were known in France and England by the 18th century. The structure of the animal has been studied by several famous anatomists, such as Owen, Duvernoy, Bischoff, and Huxley; and much information, both historical and anatomical, will be conveniently found in Professor R. Hartmann's *Anthropoid Apes* (Inter. Sc. Series, 1885). To this naturalist much of our knowledge as to the exact anatomy of the chimpanzee and related forms is due. For more general considerations, Huxley's work entitled *Man's Place in Nature* may be profitably consulted. See also his *Anatomy of Vertebrate Animals*.

Characteristics.—As the general features of Anthropoid Apes (q.v.) have been already sketched, it will be enough to sum up the more striking characteristics of the chimpanzee. The animal stands about four feet high, has very dark, all but black hair, a broad, leathery, reddish-brown face, small nose, large mouth, protruding lips, large brow-ridges, and small ears. The face has an angle of 70 degrees. The head hangs down upon the chest.

Chimpanzee (after Hartmann).

There are no cheek-pouches. The arms are very long, and reach the knee; their span is about half as much again as the height. The hand is narrow, but as long as the foot. The sole of the foot can rest flatly on the ground, and the animal readily stands or walks erect. But his favourite attitude is leaning forward, and supporting himself on the knuckles of the hand. The backbone begins to exhibit the curves characteristic of man, and the chimpanzee is alone among anthropoids in having the spine of the second neck vertebra bifurcated as in man. It has one pair of ribs in addition to the twelve possessed by man. There is of course no tail, nor are there any sitting-pads or ischial callosities. 'The volume of the brain is about half the minimum size of a normal human brain. All the gyri (ridges) of the human brain are represented

in the cerebral hemispheres of the chimpanzee; but they are simpler and more symmetrical, and larger in proportion to the brain.'

Habits.—The chimpanzee is found on the coast of Guinea and farther inland. It occupies a wider area than the gorilla, and is even said to have been found in East Africa, to the south of Abyssinia. It lives in forests, is an adept climber, but keeps a good deal to the ground. The diet consists mainly of wild fruits; but animal food seems to be occasionally eaten. The chimpanzees live in families or in small societies. They construct pent-houses in the thick forest darkness, and the males are said to pass the night below the family nest. They make a great deal of noise, of a dreary and horrible character, especially when provoked by other monkeys. Though they generally flee at the sight of man, they can with hands and teeth make themselves in extremity most formidable antagonists. The natives shoot them with arrows or javelins, or in recent days with firearms. The flesh is eaten by the natives of some parts of Africa; the skulls may serve as fetiches.

There is considerable dispute as to the species or varieties of chimpanzee. Hartmann discusses the question at length in the work already referred to, describing one distinct variety in addition to the typical *Troglodytes niger*, and admitting the possibility of hybrids. Chimpanzees are occasionally brought to European zoological gardens, but rarely stand the climate for more than two or three years. They are known to exhibit great cleverness, and admit of some education.

China. The Chinese Empire, consisting of *China Proper* and Manchuria (q.v.), with its dependencies of Mongolia, I-li, and Tibet (q.v.), embraces a vast territory in Eastern Asia only inferior in extent to the dominions of Great Britain and Russia. The dependencies are not colonies, but subject territories; and China Proper itself, indeed, has been a subject territory of Manchuria since 1644. It will be convenient, however, to confine ourselves in this article to the former.

China is not known among the people themselves as the designation of the country, and the use of the term is spreading among them only through its all but universal employment by other nations. In the oldest classical writings the country is called *Hwa Hsia*, 'The Flowery Hsia.' *Chung Kuo*, 'The Middle State,' or kingdom, grew up in the feudal period as a name for the royal domain in the midst of the other states, or for those states as a whole in the midst of the uncivilised states around them. The idea of its being 'in the middle of the earth' did not enter into the designation, though the assumption of universal sovereignty, *de jure* if not *de facto*, that has been so injurious to the nation, appears in the very ancient names *T'ien hsiä*, 'all beneath the sky,' and *Sze Hsi*, 'all within the four seas.' In the treaties with western nations concluded in the present century the empire is called by the title of the reigning dynasty, 'the Kingdom of the Great Pure (dynasty)'; and this is in accordance with the practice of Chinese writers, who are fond of calling their country 'the Land of Han,' and 'the Hills of T'ang,' from the two great dynasties so named.

Serica, *Sera*, and *Seres*, in Ptolemy and other ancient geographers, indicate China and the Chinese as the country and people producing *silk*, being taken from *sze* (silk), originally the pictorial symbol of a packet of cocoons.

Cathay, a poetical name with us, and still apparent in the Russian name for China (*Kitai*), came into use as a designation for the northern part of the empire through Marco Polo and other medieval writers. It was the Persian designation of the Tartar *K'itan* tribes which contended with

the Sung dynasty for the supremacy of the empire, then merged in the dynasty of Chin (*Kin*), and were extinguished by the Mongol conquest. The country south of the Yang-tze River was then styled *Manzi* or *Manzy*, from the old name of *Man* for all the southern aboriginal tribes.

The name China has come to us from India through Buddhism. In a conversation (apocryphal probably), related by Nien Chi'ang in his *History of Buddhism*, between the Han emperor who welcomed them to his capital and the first two of the Buddhist missionaries, there appear the names of *Chi-na* and *Chin-tan* ('the Land of Chin'). We do not know how long before our first century the name had obtained in India, nor how it originated. If it had begun with *ts* instead of *ch*, the view of many that it was derived from the great state of Ts'in, whose fortunes culminated in the first but short-lived imperial dynasty (221-209 B.C.), might have been considered as certain. This question must be left as hardly capable of determination; as also how it is that we find the empire called by the Asiatic peoples *Sin*, *Tsin*, *Tsinistan*, and the inhabitants *Tsiniste*. 'The land of Sinim,' in Isa. xlix. 12, should be added to these denominations.

CHINA PROPER was divided in the K'ang-hsi reign (1662-1722) into eighteen provinces; and since the recent separation of the island of Formosa from Fû-chien, and its constitution into an independent province (as T'ai-wan), we may say that it now consists of nineteen. These form one of the corners of the Asiatic continent, having the Pacific Ocean on the south and east. They are somewhat in the shape of an irregular rectangle, and lie, if we include the island of Hâi-nan, between 18° and 49° N. lat., and 98° and 124° E. long. Their area has been given at 1,297,300 sq. m., being more than twenty-five times that of England, but that estimate does not include large additions to Chih-li on the north-east, and Kan-sû on the north-west, made since the K'ang-hsi reign. Including these, the area is at present not much, if at all, short of 2,000,000 sq. m. (The whole empire, without Corea, has an area more than twice as large.)

On the north there are four provinces—Chih-li, Shan-hsi, Shen-hsi, and Kan-sû; on the west, two—Sze-ch'wan (the largest of all) and Yun-nan; on the south, two—Kwang-hsi and Kwang-tung; on the east, four—Fû-chien (Kien—the initial *ch* used to be pronounced *k*), Cheh-chiang, Chiang-sû, and Shan-tung. The central area inclosed by these twelve provinces is occupied by Ho-nan, An-hui (Gan- and Ngan-lwei), Hû-pei, Hû-nan, Chiang-hsi, and Kwei-châu (a poor province, but with parts of it largely occupied by clans or tribes of aboriginal Miao-tsze). The island of Formosa, lying off the coast of Fû-chien, 90 miles W. of Amoy, is about 235 miles in length, fertile, and rich in coal, petroleum, and camphor-wood. The first settlement of a Chinese population only took place in 1683, and the greater part of it is still occupied by aboriginal tribes of a more than ordinarily high type.

The population of these provinces is immense, but the various censuses that have been adduced by inquirers vary and fluctuate so much that the writer entirely agrees with the late Dr Williams in holding that, 'until there has been a methodical inspection of the empire' published and guaranteed by the government, questions concerning the population must be held in abeyance (*The Middle Kingdom*, 2d ed. preface, p. 10). The *Almanach de Gotha* for 1888, basing its conclusions on reports of the imperial maritime customs, gives for all the provinces a total of 381½ millions. The late ambassador in England, however, the Marquis Ts'ang, writes in the *Asiatic Quarterly Review* of January

1887 of 'the awakening of 300 millions to a consciousness of their strength!' Our own impression is that 400 millions is not an overestimate of the population of the Chinese empire. Of the twenty-two ports open to foreign commerce, only five have a population under 50,000. That of Canton is estimated at 1,600,000; of T'ien-tsin at 950,000; of Han-k'au at 750,000; of Fû-châu at 630,000; of Shang-hai at 355,000; of Ning-po at 240,000.

As to the physical features of China Proper, the whole territory may be described as sloping from the mountainous regions of Tibet and Nepal towards the shores of the Pacific on the east and south. The most extensive mountain-range in it is the Nan Ling or Southern Range, a far-extending spur of the Himalayas. Commencing in Yun-nan, it bounds Kwang-hsi, Kwang-tung, and Fû-chien on the north, and, passing through Cheh-chiang, enters into the sea at Ning-po. It thus forms a continuous barrier, penetrated only by a few steep passes (of which the Mei Kwan is the best known) that separates the coast-regions of South-eastern China from the rest of the country. This great chain throws off numerous spurs to the south and east, which, dipping into the sea, appear above it as a belt of rugged islands along the seaboard. Of this belt the Chusan Archipelago is the most northerly portion.

North of this long range, and west of the 113th meridian, on to the borders of Tibet, the country is mountainous, while to the east and from the great wall on the north, to the Po-yang lake in the south, there is the *Great Plain*, comprising the greater part of the provinces of Chih-li and Shan-tung, Ho-nan, An-hui, and Chiang-sû—an area of about 210,000 sq. m., estimated to support a population of 177,000,000.

In the provinces west from Chih-li—Shan-hsi, Shen-hsi, and Kan-sû—the soil is formed of what are called the loess beds, which extend even to the Koko-nor and the head-waters of the Yellow River. The name loess is adopted from that of a Tertiary deposit which appears in the Rhine Valley—a brownish coloured earth, extremely porous, crumbling easily between the fingers, and carried far and wide in clouds of dust. It covers the subsoil to an enormous depth, and is apt to split perpendicularly in clefts which render travelling difficult. And yet by this cleavage it affords homes to multitudes of the people, who live in caves excavated near the bottoms of the cliffs. Sometimes whole villages are so formed in terraces of the earth that rise above one another. But the most valuable quality of the loess is its fertility, the fields composed of it hardly requiring any other manure than a sprinkling of its own fresh loam. The husbandman in this way obtains an assured harvest two and even three times a year. This fertility, provided there be a sufficient rainfall, seems inexhaustible. The province of Shan-hsi has borne the name for thousands of years of 'the Granary of the Nation;' and it is no doubt to the distribution of this earth over its surface that the Great Plain owes its fruitfulness.

The rivers of China—called for the most part *ho* in the north, and *chiang* (*kiang*) in the south, are one of its most distinguishing features. Two of them stand out conspicuous among the great rivers of the world; the Ho, Hoang-ho, or Yellow River, and the Chiang, generally misnamed the Yang-tze. They rise not far from each other; the Ho, in the plain of Odontala, called in Chinese the 'Sea of Stars'—i.e. of springs or lakelets, in 35½° N. lat., and 96° E. long.; and the Chiang (Kiang), from among the mountains of Tibet. The Ho pursues a tortuous eastward course to Kan-sû, and the Chiang with a southern inclination enters China at Batang, in Sze-ch'wan. From the prefecture of Lan-châu the Ho flows north-east more or less along the Great Wall, till it arrives

nearly at the northern limit of Shen-hsi, when it turns directly south, and flowing for 500 miles between that province and Shan-hsi, comes to the edge of the Great Plain, and pursues an eastward course. The Chiang on the contrary flows south from Batang, between Sze-ch'wan and Yun-nan, till it reaches the southern limit of the former province. Then it turns north, and holds its way eastward through Sze-ch'wan and the other intervening provinces till it enters the ocean in lat. 32°. The Ho does not pursue so regular a course. Its direction indeed from the edge of the plain is eastwards, but in the course of time it has ever and anon changed its channel. Chinese history opens, in the Shû King, in the 24th century B.C., with an account of one of its inundations, described in terms which have suggested to some students the Noachian deluge, and the labours on it of the Great Yü. The terrible calamities caused by it so often have procured for it the name of 'China's Sorrow.' So recently as 1887 it burst its southern bank near Ch'ang Ch'au, and poured its mighty flood, with hideous devastation and the destruction of millions of lives, into the populous province of Ho-nan. It is now the task of the Manchû rulers of the empire to remedy this disaster, and regulate the terrible river for the future. Both the Ho and the Chiang must have a course of more than 3000 miles. These two rivers are incomparably the greatest in China, but there are many others which would elsewhere be accounted great. And among those rivers we may well account the *Grand Canal*, intended to connect the northern and southern parts of the empire by an easy water communication; and this it did when it was in good order, extending from Peking to Hang-ch'au in Cheh-chiang, a distance of more than 600 miles. The glory of making this canal is due to Kublâi, the first sovereign of the Yüan dynasty, of whom Marco Polo says: 'He has caused a water communication to be made in the shape of a wide and deep channel dug between stream and stream, between lake and lake, forming as it were a great river on which large vessels can ply.' Steam communication all along the eastern seaboard from Canton to T'ien-tsin has very much superseded its use, and portions of it are now in bad condition, but as a truly imperial achievement it continues to be a grand memorial of Kublâi. Even Barrow wrote of it in 1806: 'In point of magnitude, our most extensive inland navigation in England can no more be compared to the grand trunk that intersects China than a park or garden fish-pond to the great lake of Winandermere.'

After the Grand Canal a few sentences may be given to the *Great Wall*, another vast achievement of human labour, especially as in 1887 there were paragraphs in many of our newspapers representing its existence as merely a myth. Not so useful as the canal, and having failed to answer the purpose for which it was intended—to be a defence against the incursions of the northern tribes, there it still stands, while the walls of Hadrian and Antoninus in our own country have crumbled to the ground, and their course can only be indistinctly traced here and there. It was in 214 B.C. that Shih Hwang Ti determined to erect a grand barrier all along the north of his vast empire. The wall commences at the Shan-hai Pass (40° N. lat., 119° 50' E. long.), where it was visited by a squadron of Her Majesty's vessels of war in 1839, and was seen, as Lord Jocelyn describes it, 'scaling the precipices, and topping the craggy hills of the country.' From this point it is carried westwards till it terminates at the Chia-yü barrier gate, the road through which leads to the 'Western Regions.' Its length in a straight line would be 1255 miles, but, if measured along its sinuosities, this distance must be increased

to 1500. It is not built so grandly in its western portions after it has met the Ho River, nor should it be supposed that to the east of this point it is all solid masonry. It is formed by two strong retaining walls of brick, rising from granite foundations, the space between being filled up with stones and earth. The breadth of it at the base is about 25 feet, at the top 15, and the height varies from 15 to 30 feet. The surface at the top was covered with bricks, and is now overgrown with grass. What foreigners go to visit from Peking is merely a loop-wall of later formation, inclosing portions of Chih-li and Shan-hsi.

The lakes are very many, but not on so great a scale as the rivers. It will be sufficient to mention three—the Tung-ting Hû, the largest, having a circumference of 220 miles, and entering into the names of the provinces Hû-pei and Hû-nan; the Po-yang Hû, in the north of Chiang-hsi, the seat of the manufactories of the best porcelain; and the T'ai Hû, partly in Chiang-sû and partly in Cheh-chiang, famous for its romantic scenery and numerous islets.

The country is rich in the products necessary for the support and comfort of the people, and for the adornment of their civilisation. There is in it every variety of climate; but the average temperature is lower than in any other country in the same latitude. The Chinese themselves consider Kwang-tung, Kwang-hsi, and Yun-nan to be less healthy than the other provinces; but foreigners using proper precautions may enjoy their life in every province.

Wheat, barley, maize, millet, and other cereals are chiefly cultivated in the northern regions, and rice in the southern. The writer once had a bag of oatmeal sent to him from Kalgan, north of the loop-wall mentioned above. Culinary or kitchen herbs, mushrooms, and aquatic vegetables, with ginger and a variety of other condiments, are everywhere produced and largely used. From Formosa there comes sugar, and the cane thrives also in the southern provinces. Oranges, pummeloës, litchis, pomegranates, peaches, plantains, pine-apples, mangoes, grapes, and many other fruits and nuts, are supplied in most markets. Tea is noted below. Opium has been increasingly grown of late within the country. The Chinese are emphatically an agricultural people. From time immemorial the sovereign has initiated the year, which begins with the spring, by turning over a few furrows in the 'sacred field'; and in each province the highest authority performs a similar ceremony—to impress on the people the importance of husbandry. The hoe holds the place of our spade; the plough retains its primitive simplicity; irrigation is assiduously and skilfully employed. The *tsing*, or well, which was anciently in the centre of the plots of land assigned to the families which cultivated them, is still seen in the north; and where the canal or river-beds are below the level of the fields much ingenuity is displayed in raising the water to them by wheels and scoops. No other people show such a sense of the value of human ordure as manure. Nothing that comes from man or beast is allowed to be lost. All is preserved and prepared for use. This does not conduce to the cleanliness of the towns or the fragrantcy of the country; but it largely increases the productiveness of the field and the garden.

The horse, the ox, the sheep, the fowl, the dog, the pig; these are the six animals which men breed for food,

are well-known lines; but we do not now hear of horses being eaten; and though dogs are to be seen in baskets in the markets, or cut up on the stalls, they are such as have been carefully fed. Fowls, including ducks and geese, are abundantly bred and consumed; of ducks, immense numbers

are artificially hatched. Comparatively little beef is eaten, not so much because of the prevalence of Buddhism, which forbids the taking of life, as from a feeling of gratitude to the animal which renders the most important service in tilling the ground. Pork is the most used of all flesh meat, and the number of pigs is enormous. In addition to these animals, the seaboard, rivers, lakes, and ponds supply an immense quantity of excellent fish taken by the net. Angling is not much practised; but a boat with its complement of cormorants, trained to dive for the fish and bring them to their masters, is a pleasant sight. Shellfish also yield their quota to the food of the people. An idea is prevalent that the Chinese are gross feeders, but this is true only of the very poor. A first-class Chinese dinner with its twenty-seven courses may hold its own with most luxurious tables. The famed birds'-nest soup is a misnomer. Nests of the *Collocalia esculenta*, brought from the Indian Archipelago, are sliced into other soup, and supposed to impart to the compound an invigorating and stimulating quality, but the writer never felt that it added either to its flavour or piquancy.

For beverages the use of tea has nearly superseded every other. The plant does not grow in the north, but is cultivated extensively in the western provinces and in those south of the Great Chiang. The infusion of the leaves was little, if at all, drunk in ancient times, but now its use is universal. Fû-chien, Hû-pei, and Hû-nan produce most largely the black teas; the green comes chiefly from Cheh-chiang and An-hui; both kinds come from Kwan-tung and Sze-ch'wan. Next to silk, if not equally with it, tea is China's most valuable export; and by nothing does it contribute more to the comfort and well-being of the rest of the world. To the people themselves its use has been invaluable, and more than anything else has promoted the temperance that is characteristic of them. They are acquainted with distillation, and from rice and millet produce alcoholic liquors. Their literature abounds from the 12th century B.C. to the present dynasty with warnings against the injury of strong drink; but more effectual than the proclamations of authority has been the habit of drinking tea. As compared with the populations of western nations, the Chinese are sparing in the use of strong drink, and it is rare to see one of them intoxicated. They do not sit down to tea as a special meal, nor do they make it so strong as we do, or add sugar or cream to it, but they have it at hand, and offer it to visitors, all day long. The ordinary name of the plant is *ch'á*; but the leaf was first imported into England from Amoy in Fû-chien, where the dialectical pronunciation of the name is *t'ay*, which the Irishman still retains. The use of opium will be discussed in a separate article.

The next essential to food and drink in the economy of life is *clothing*, and for this China has abundant provision in its stores of silk, linen, and cotton. It was no doubt the original home of *silk*. From the 23d century B.C. and earlier, the care of the silkworm, and the spinning and weaving of its produce, have been the special work of woman. As it is the duty of the sovereign to turn over a few furrows in the spring to stimulate the people to their agricultural tasks, so his consort should perform an analogous ceremony with her silkworms and mulberry-trees. The tree grows everywhere, and in all the provinces some silk is produced; but Kwan-tung, Sze-ch'wan, and Cheh-chiang furnish the best and the most. The manufactures of silk are not inferior or less brilliant than any that are produced in Europe, and nothing can exceed the embroidery of the Chinese. Indigenous to the country also are hemp and other fibrous plants, such as the *Bahmeria nivea*, from which

the grass-cloth is made. The cotton-plant, though not indigenous, appears to have been introduced from Khoten (Eastern Turkestan) in the 11th century, and is now found everywhere, but is cultivated most extensively in the great basin of the Chiang. The well-known *nankeen* is named from Nanking, a centre for its manufacture. The Chinese cotton is inferior to the imported cloth in its finish, but is heavier and more durable. (For the flora of China, see ASIA, Vol. I. p. 491.) Of *woollen fabrics* the production is not large; but we meet with felt caps, rugs of camels' hair, and furs of various kinds. As the houses have no fireplaces, people keep themselves warm in cold weather by increasing the number of garments which they wear. On the whole China has more resources in itself for the comfortable support and clothing of its vast population than most other countries.

For *building materials* the Chinese use, like ourselves, timber, bricks, and stone; but in the south inexpensive houses are often made of a kind of concrete called 'sifted earth,' a compound of decomposed granite and lime, with the addition sometimes of a little oil, pounded in a wooden framework, which is shifted till the walls have reached their intended height. Anciently, as we learn from the Shih King, the largest structures were raised in this way. The walls, if well protected by overhanging eaves and plaster against wet, are strong and durable. Granite and limestone are found in many places, and the largest rocks are ingeniously split and wrought into building blocks. The architecture of China is defective, however, in the grandeur and grace which mark that of some other countries; the best specimens of it are seen in the marble bridges and altars of Peking, and in the Buddhist buildings on the 'Hill of Longevity' and other places in the neighbourhood. No one who has seen them can ever forget the gigantic figures of animals and the statues lining the road that leads to the tombs of several of the Ming emperors, a considerable distance north from the capital. In the country, houses are seldom of more than one story. Even in the cities the public offices and large business establishments are not remarkable for their height, but for their depth, as you pass from one series of rooms to another through intervening courts. Rising conspicuous above the other buildings are the pawn-brokers' establishments, whilst the most substantial and elegantly finished structures are the guildhalls belonging to the various trades, or to the merchants congregating in them from the different provinces.

The most *picturesque* buildings are the pavilions and pagodas. Of the former the most striking is one in what has become famous by being misnamed the 'Summer Palace' at Peking, about 14 feet square and 20 high, made of pure copper. The pagodas are Buddhist structures, borrowed from the toposes of India, where they were built at first as depositories for the relics of Buddha and distinguished Arhats. In China they have taken a peculiar form, and are supposed to exercise mysterious geomantic influences. They are the most remarkable objects in the landscapes of the country, and there are few cities which cannot boast of one or more, always of an uneven number of stories. The most celebrated of them, the Porcelain Tower of Nanking, is now a thing of the past, having been blown up by the iconoclastic T'ai-p'ings in 1858. It was of an octagonal form, and was intended to be of thirteen stories, rising to a height of 329 feet; but only nine stories were completed, the building of which took nineteen years (1411-30). It was built massively of brick and faced with slabs of glazed porcelain—green, red, yellow and white; with lamps hanging outside from the projections of the

different stories—one of the architectural wonders of the world.

In the cities, and studding the country also, are many *Pai-laus* or *Honorary Portals*, which often carried the writer's thoughts to the old Temple Bar, though not of so substantial a construction as it was. They are tokens of imperial favour, erected in honour of distinguished persons, and many of them signalling the virtue of widows who steadfastly refused to be married a second time.

The streets of the cities, especially in the south, are not wider than so many lanes, and the streams of people hurrying through them give the stranger an idea that they are more populous than they really are, though against this hasty assumption must be set the rarity of the appearance of women in them. They are paved with slabs of stone, but badly drained, and the heat and stench render a promenade through them anything but agreeable. Most of them have high-sounding names, such as 'The Street of Benevolence and Righteousness.' As in the old Roman cities, tradesmen of the same pursuits are found very much together in the same street. The streets are wider in the northern cities, till we arrive at Peking, where the wide ways of the Manchú portion combine with the imposing walls and their lofty towers to make the visitor think for a time that he has arrived at the grandest city of the world.

When you enter the house of a well-to-do family, you find the furniture sufficient, though somewhat scanty and not luxurious. The floor may be covered with matting, but not with a carpet or rugs. The tables and straight-backed chairs are of a dark, heavy wood resembling ebony. A few pictures, not works of art, are hung on the walls, along with scrolls of fine writing, expressing moral sentiments or historical and topographical references, while some jars and other specimens of fine porcelain are put down here and there. There may be a couch or two made of bamboo and rattan, and stools of the same materials. The *bamboo*, that queen of the *Arundinaceæ*, deserves especial mention. A clump of bamboos adds a graceful charm to the scenery, and there seems to be no end to the uses which the plant serves. The schoolmaster employs it for his ferule, and the mandarin or magistrate for his most common instrument of punishment. The writing-paper is made from it. Its young shoots are used for food, and for comfits and pickles. Its stems, according to their size, are employed for pencil handles, for canes, and for poles. Fans, cages, baskets, and fish-creels are all constructed with it. Its roots are carved into grotesque figures, and fashioned into blocks of a peculiar shape to be used in divination. China would not be China without the bamboo.

The country is too thickly peopled and well cultivated to harbour many *wild and dangerous animals*, though one occasionally hears of a tiger that has ventured from the forest and been killed or captured. The lion was never a denizen of China, and is only to be seen rampant in stone in front of temples. The rhinoceros, elephant, and tapir are said still to exist in the forests and swamps of Yun-nan; but the supply of elephants at Peking for the carriage of the emperor when he proceeds to the great sacrificial altars has been decreasing for several reigns. Both the brown and black bear are met with, and several varieties of

the deer family. The musk-deer is greatly valued. Among the more *domestic quadrupeds*, the breed of horses and cattle is dwarfish, and no attempts seem to be made to improve them. The ass is a more lively animal in the north than with us, and

Temple of the Goddess Ma Tsu-pu, Ning-po.
(From *The Middle Kingdom*, by S. W. Williams, LL.D.)

receives more attention. About Peking one is struck by many beautiful specimens of the mule. Princes are seen riding on mules, or drawn by them in elegant litters, while their attendants accompany them on horseback. The camel is only seen in the north. One of the first things that strikes a stranger in the capital is the troops of the shaggy animal lying or feeding about the walls, with their Mongol keepers, looking as uncouth as their charge.

The *birds of prey* are many. Minors, crows, and magpies abound. The last are 'sacred birds,' which it is not safe for the traveller to shoot. The people are fond of song-birds, especially the lark, the thrush, and the canary. The song of the nightingale is familiar. The smaller birds are not so afraid of man as with us. Buddhism, with which life is sacred, has done much to secure for birds, both with old and young, immunity from molestation and death. The lovely gold and silver pheasants are well known, and also the *Yüan-yang* (*Anas galeuculata*), or mandarin duck, the emblem to the Chinese of conjugal fidelity.

The people are fond of *flowers*, and make excellent gardeners. You look in vain, however, in the gardens of the wealthy for the gay parterres which so please the eye in England. They cultivate their favourites mostly in pots; and the 'willow-plate pattern,' with its arbours, bridges, and ponds, glowing often with the large and brilliant flowers of the nelumbium, supplies a good picture of a Chinese garden of a superior order.

While the Chinese have, as we have seen, done justice to most of the natural capabilities of their country, they have greatly failed in developing its *mineral resources*. The skill which their lapidaries display in cutting crystal and other quartzose minerals is well known, and their work in jade, which they so highly prize, is very fine. But a mineral more valuable than any other has been comparatively neglected. The *coalfields* of China are enormous—more than twenty times the extent of those of Great Britain; but up to this time the majority of them can hardly be said to have been more than scratched. Immense quantities of iron ore, moreover, must have been extracted from the earth during the millenniums of its history, but a much greater amount is still untouched. Copper, lead, tin, silver, and gold are known to exist in

many places, but little has been done to make the stores of them available. More attention has been directed to their mines since the government and companies began to have steamers of their own; and a scheme has been approved by the government for working the gold-mines in the valley of the Amoor River. The government has become conscious of its mineral wealth, and there is no calculating the resources to which it may attain.

A gold and silver currency is one of the first things which it has to provide. Thus far the only currency has been the copper *cash*, cumbrous and often debased, varying in its relative value in every district, and the source of endless trouble to the traveller. Even foreign silver coins are treated as bullion, and taken by weight. What is called 'sycee silver' is made from them. After they have been defaced and broken to pieces, they are melted and cast into ingots of different sizes called 'shoes.' The comfort of the housekeeper, as well as of the traveller, is interfered with by the necessity of keeping small fine scales or steelyards to weigh every outlay and receipt. Paper money is indeed in circulation, but the banking system exists as yet only in a rudimentary condition.

Another want in China is that of *good roads and comfortable conveyances*. The necessity for good roads first presented itself to Shih Hwang Ti (214 B.C.), who, after he had extended the empire to nearly its present limits, ordered the preparation of them seven years before he commenced the building of the Great Wall; and it has been said that there are now 20,000 roads in China; but according to the reports of travellers in the present century, the good roads among them are very few. The government couriers perform their journeys on horseback. Where communication by water is abundant the want of roads is not so much felt; but in their absence in times of scarcity it is a most difficult thing to convey supplies to starving populations, as in the famine which prevailed in Shan-hsi and other northern provinces a few years ago. It is owing doubtless to the want of roads that the wheelbarrow is so much used as the chief vehicle of communication and commerce from the Chiang northwards. The writer once had an experience of this, when, along with a companion, he was conveyed 280 miles on one of those 'cany wagons light' in about 8 days. Slow as the journey was, the fatigue was much less than if they had been jolted over the same distance in a springless mule-cart in half the time. Even at Peking roads once paved with marble slabs have been allowed to fall into such a state of dilapidation as to be full of discomfort and danger; and the route and conveyances from the capital to T'ien-tsin, its port, are disgraceful to the government.

Social Habits.—The dress of the poor is very much alike in both sexes; and though it is regulated for all classes by sumptuary laws, it is varied among the wealthy by the richness of the materials and the various ornamentation. The most striking thing in the appearance of the men to a foreigner is the *queue* or *plaited tail* from the hair of the crown, all the rest of the head being shaved. This was not the old fashion of doing up the hair, but was enforced on the Chinese by the Manchus in 1627, when they had commenced the conquest of the empire. Inscriptions on stone tablets in old temples in Japan, erected by refugees of the 17th century, mention this degrading requirement as one of the reasons why they had fled from their country. All dislike to the custom, however, has now disappeared. A foreigner is surprised in the same way by the *small feet* of the more respectable women. These were not enforced upon them by the Manchu conquerors, whose women allow their feet to grow to the natural size, nor was it a very

ancient practice in the country, though it seems to have prevailed since our 6th century. The distortion is produced by bandaging the feet in early

Foot of Chinese Girl (aged 16 Years), in three positions:
Copied from a cast in Trinity College, Dublin.
(Length of foot, 4½ inches.)

years, so as to prevent their further growth. The very poor and servants are not subjected to this torture, but such is the force of fashion that we have known humble girls of twelve or thirteen vainly try to reduce the size of their feet, thinking thereby to make themselves more attractive.

The separation of the sexes until marriage has been a feature of the social life from the earliest times. In the old feudal period, 'at the age of seven, boys and girls of the same family did not occupy the same mat, nor eat together, and at the age of ten a girl ceased' to appear outside the women's apartments. Her governess taught her the arts of pleasing speech and manners, to be docile and obedient, to handle the hempen fibres, to deal with the cocoons, to weave silks and form fillets, to learn all woman's work, how to furnish garments, to watch the sacrifices, to supply the liquors and sauces, to fill the stands and dishes with pickles and brine, and to assist in setting forth the appurtenances for the ceremonies. At fifteen she assumed the hairpin (as a token that she had arrived at woman's estate), at twenty she was married, or if there were occasion for the delay, at twenty-three. We read nothing of any literary training for the daughters then, nor is there any now, though Chinese history is not without instances of learned women and distinguished authoresses. In the important event of *marriage* the parents exercise a supreme control; and this has given rise to the class of *match-makers* or *go-betweens*, who are consulted by the parents, make inquiries, and by an examination of the horoscopes of the parties and other methods of their profession determine the question of the mutual suitability of the match. When a marriage has been agreed upon, it is carried through with a great variety of ceremonies, the parties most concerned being supposed never to have previously seen each other. In the majority of cases the husband and wife thus brought together seem to take to each other very well. Notwithstanding its defects and differences from our ideal, its result seems to be a fair amount of peace and happiness. When the wife becomes a mother she is treated as a sort of divinity in the household. There is but one proper wife (*ch'ang-ch'ü*) in the family, but there is no law against a man's having secondary wives or concubines; and such connections are common wherever the means of the family are sufficient for their support. Many of the greatest names in the nation's history are stained with this practice, and the evils of it have been and are very great. There are seven legal grounds for divorcing a wife: Disobedience to her husband's parents; not giving birth to a son; dissolute conduct; jealousy (of her husband's attentions—i.e. to the other inmates of his harem); talkativeness;

thieving; and leprosy. These grounds, however, may be nullified by 'the three considerations: ' If her parents be dead; if she have passed with her husband through the years of mourning for his parents; and if he have become rich from being poor. In many cases the betrothment of children is made at an early age, leading often to injurious and melancholy issues.

The charge of *infanticide* has been brought against the family life in China, the victims in the vast majority of instances being the female children. That it is stained by this crime, though not to the extent that has often been alleged, cannot be denied. It is among the very poor that the barbarity is chiefly perpetrated, and their poverty is the reason of it. From the ancestral worship which prevails among the people, the *desire for male children* is greater in China than perhaps in any other country. In one case the wife of a professing Christian asked the writer whether her husband might not be allowed, like any other person, to bring a concubine to the house, as children were denied to herself, and she would bring up any boy that might be born on her knees as her own child. Public opinion is certainly against the crime of infanticide; the government is to blame in that it does not address itself to punish the deed and put it down. Even the public opinion against it is not so emphatic as it ought to be. Foundling hospitals and asylums for the aged are to be found in most of the large towns, but their cleanliness and management are not satisfactory.

The complexion of the Chinese inclines to yellow —, as they say themselves, of 'the colour of the olive.' The same coarse black hair and apparently oblique eyes, with high cheekbones and roundish face, belong to them all from the Great Wall to the island of Hâi-nan. They are stout and muscular as compared with other eastern peoples, temperate, industrious, cheerful, and easily contented. They are addicted to gambling, and are generally held to be given also to mendacity and larceny. Many of them are so; and where is the country where there are not many such? The longer one lives among them, however, the better he likes them, and the better he thinks of them.

They *bury* their dead in graves which are built round in the form of a horseshoe, and often with much display and at great expense. The mourning rites are tedious, and embrace a variety of sacrifices and other observances. No subject occupies so large a portion of the Classic of Ritual Observances.

There is no *weekly day of worship and rest* like our Sunday. At the New Year the government offices are shut for about a month. New-year's Day is the one universal holiday, and at this time shops are closed for several days. The whole nation seems to be dissolved in festivity and joy. The people dress in their best; the temples are visited; gambling tables are surrounded by crowds; the noise of fireworks or 'crackers' is incessant. Throughout the year every month has its festivals, of which the most general are that of 'Lanterns,' on the full moon of the first month; of the 'Tombs,' later on in the spring; of 'Dragon Boats,' in the fifth month; and of 'All Souls,' in the seventh month, for the benefit of departed relatives and hungry ghosts in the world of spirits. Theatrical representations are immensely popular. 'Strolling companies' can easily be hired; with the bamboo and matting, sheds, often very large, can be readily erected for the exhibition. Individual actors become celebrated as with us, and their services are well remunerated. Females do not appear on the stage. Their parts are performed by boys got up for the purpose.

History.—The chronology of China is measured not by centuries, but by sexagenaries, the first

cycle being made to commence with the sixtieth year of Hwang Ti in 2637 B.C. But this is merely a conventional arrangement. There were Chinese in China before Hwang Ti, and the cycle names for the years prior to 827 B.C. cannot be fully relied on. The documents of the Shû King begin with the reigns of Yâo and Shun (2356-2206 B.C.); and from various intimations in that work we are brought to conclude that the nation then consisted of a collection of tribes or clans of the same race, ruled by a sovereign, nominated by his predecessor, and approved by the people as the worthiest man to reign over them.

With Yü, the successor of Shun, and the hero of Yâo's deluge to which we have already made reference, there came a change in the principle of succession to the throne. As it is expressed, 'He *familied* the kingdom.' Then commenced the *Feudal State*, which lasted under three dynasties (Hsia, 2205-1767 B.C.; Shang or Yin, 1766-1123 B.C.; and Châu, 1122-255 B.C.) for a period of nearly two thousand years. The feudal system of China was very similar to that which prevailed in Europe during what we call the middle ages. At a grand *durbâr* held by Yü after his accession there were, it is said, ten thousand princes present with their jade symbols of rank. But the feudal states were constantly being absorbed by one another. On the rise of the Shang dynasty they were only somewhat over three thousand, which had decreased to thirteen hundred when King Wû established the sovereignty of the Châu. In 403 B.C. we find only seven great states, all sooner or later claiming to be 'the kingdom,' and contending for the supremacy, till Ts'in (Ch'in) put down all the others, and in 221 B.C. its king assumed the title of Hwang Ti, or Emperor, and determined that there should be no more feudal principalities, and that, as there is but one sun in the sky, there should be but one ruler in the nation.

From that year dates the *imperial* form of the Chinese government, which has thus existed for more than 2100 years. The changes of dynasty have been many, two or more sometimes ruling together, each having but a nominal supremacy over the whole nation. The greater dynasties have been those of Han (206 B.C.-220 A.D.), Tang (618-906), Sung (960-1279), Yüan (the Mongol, 1280-1367), the Ming (1368-1643), and the Ch'ing (Manchû-Tartar, 1643 to the present date).

The long and persistent existence of the Chinese nation has been owing partly to its geographical position keeping it apart from other great nations, and partly to its educational culture and training. Where the race came from at first takes us beyond the footsteps of history. The Chinese were not the earliest inhabitants of the country. They made their way from the north and west of China proper, pushing before them the older inhabitants, exterminating them or absorbing them, or leaving portions of them within their own ever-enlarging borders, as wrecks of tribes still subsisting here and there, and apparently mouldering to extinction. From the first appearance of the Chinese we find among them written characters (see the next article), and certain elements of intellectual and moral culture and religious beliefs. (The connection of Chinese culture with that of ancient Babylonia has been suggested but not proved.)

The *Ruler* and the *Sage* confront us in the earliest records of the nation; the Ruler to govern the people, and the Sage or Man of Intelligence to assist and advise him, and spread abroad among them the lessons of truth and duty. It is said in a document of the 18th century B.C., 'Heaven gives birth to the people with such desires that without a Ruler they will fall into all disorders, and heaven again gives birth to the Man of Intelligence to

regulate them.' Thus the sovereign and the sage are both the ordinances of heaven; and it has been the rule in the various stages of the nation's history that officers of the government should possess whatever educational culture its institutions could supply. The same written character (*shih*) serves to designate both a scholar and an officer, and of the 'four classes of the people, scholars or officers, agriculturists, mechanics, and merchants,' the first has always been held to be 'the head.' Even in the feudal times the system of examinations for the selection of the officials existed in a rudimentary state, though it was not till our 7th century that it began to assume its present form, open to all, excepting 'monks, play-actors, and menial servants.'

This competitive system, as now existing with all the necessary machinery, is organised in three principal gradations—the provincial, the metropolitan, and the palace examinations. The students of each province who have attained at the district examinations to the style of *Hsiä Ts'üi*, or 'men of talent,' assemble at the provincial capital,

where as a rule every third year special examiners from Peking conduct the examination for the degree of *Chü (Kü) jän*, or 'men for promotion,' which perhaps three in a thousand of them may obtain, and which entitles them to some minor appointments. To take the third degree of *Ts'in shih*, or 'men to be presented to the emperor,' the successful *Chü-jän* from all the provinces must proceed to the metropolis, perhaps about six thousand in all, and there, also as a rule triennially, pass a test examination, the successful candidates at which then go in for the *palace examination*, conducted within the precincts of the imperial palace itself; after which the lists are published in three classes, the first being a tripos of the three best men, who become for the time the heroes of the day. They and a proportion of the others are admitted to the ranks of the members of the Han-lin, the 'Forest of Pencils,' or 'Grand Academy of Literature.' The remainder receive appointments in the provinces or at the capital, according as vacancies occur. Such is an outline, as large as our space will allow, of the competitive system of examina-

A Chinese School when the master has gone out (Peking). (From a Chinese Picture.)

tions by which the government of China seeks to secure the ablest men of the empire for its service. The examinations are testing and fairly conducted. The subjects are taken from the literature of the country itself. There are already indications not a few that the system will undergo the modifications made necessary by the new relations with other countries which have arisen in our own time; mathematics became a subject of examination in 1888. The system has tended to impress the people with the value of education; but it must not be supposed that as a whole they are highly educated. Everywhere indeed there are primary schools, not governmental, but maintained by the people themselves. A smattering of education is widely diffused; but apart from the official classes, those who can read freely or write readily are few.

The three religions of China are Confucianism, Taoism, and Buddhism. Most writers represent the first not so much as a religion, but as a morality; but there always underlies its teachings a recognition of the religion which prevailed in the country from the most ancient times—the belief of a Supreme Power, expressed at first by the name 'Heaven,' which soon came to be designated also by the personal names *Ti*, 'the Ruler,'

and *Shang-Ti*, 'the Supreme Ruler.' The state worship of Heaven or God was, and still is, confined to the sovereign as the father and priest of the people. The will of God is to be learned from the moral principles of man's nature. Government is ordained by God for the good of the people, and as soon as a sovereign ceases to seek that good and his rule is antagonistic to it, he has forfeited his title to the throne; and thus it is that the changes of dynasty are always referred to as 'the will of Heaven,' and the sovereign professes to be such 'by the grace of God.' Associated with the worship of Heaven or God, there was the worship of heaven and earth and the powers of nature, but only as subordinate to God and fulfilling His will for the good of men; and also of distinguished men, as having by their discoveries and achievements defended, benefited, and blessed the people of their own and future times. There was also common to their sovereign and all the people the worship of their ancestors. This last was and is considered as an expression of filial piety, the perpetuation of 'the duty which every one owes to his parents—the first and chief of all virtues.' On this Confucius laid great stress, endeavouring to develop all other virtues from it.

His great object may be said to have been the inculcation of *duty*, setting forth with wondrous iteration the character of his superior or ideal man. Several times he enunciated 'the golden rule' in a negative form, 'What ye would not that men should do to you, do not do to them.' *Taoism* derives its name from the treatise of Li Urh, commonly called Láo-tsze, a contemporary of Confucius, called 'The *Tao* or *Way* and its Characteristics.' The *Way* is the quiet, passionless discharge of all which our nature and relations prompt or require us to do, without striving or crying, and the method of maintaining and preserving life. 'Heaven' in this 'Way' is not a ruler or legislator as in Confucianism, but only a pattern. The system was older than Láo-tsze, and indigenous in China, but associated with many superstitions; and after the entrance of Buddhism into China it adopted many of its peculiarities. The recognised head of *Taoism* has his seat on the Lung-há Mountain in Chiang-hsi. Láo-tsze has the merit of having formulated the grand principle that good will overcome evil, and should be returned for it. For Buddhism, which was introduced or rather invited to China in our first century, see the article BUDDHISM.

There is no priesthood in Confucianism; but Buddhism has its monks and nuns, and *Taoism* its monks. The government, while not interfering with the internal organisation of either of these systems, has established a scheme of gradations of rank and authority in order that it may have the control of them in its own hands. It would no doubt recognise Christianity in the same way, if the different missions could possibly be amalgamated, and would unitedly try to adapt themselves to the bed of Procrustes which it would prepare for them in the various departments and districts. This is not the place in which to speak of the comparative number of the adherents of the 'three religions' in China. To claim a majority for those of any one of them is very absurd. As a matter of fact, Confucianism represents the intelligence and morality of China; *Taoism* its superstitions; and Buddhism its ritualism and idolatry, while yet it acknowledges no God.

THE GOVERNMENT of the empire (omitting the regulation of the imperial court and family, or the special Manchú department) is conducted from the capital, supervising, directing, controlling the different provincial administrations, and exercising the power of removing from his post any official whose conduct may be irregular or considered dangerous to the state.

There is the *Grand Cabinet*, the privy-council of the emperor, in whose presence it meets daily to transact the business of the state, between the hours of four and six A.M.! Its members are few, and hold other substantive offices. There is also the *Grand Secretariat*, formerly the supreme council, but under the present dynasty very much superseded by the cabinet. It consists of four grand and two assistant-grand secretaries, three of them Manchús and three Chinese.

The business on which the cabinet deliberates comes before it from the *Six Boards*—of Civil Office, of Revenue, of Ceremonies (including all matters pertaining to religion), of War, of Punishment, and of Works. Each Board has two presidents and four vice-presidents, three of them again Manchús and three Chinese. In 1861 the changed relations between the empire and foreign nations led to the formation of what we may call a seventh Board, styled the 'Ya-mán (or court) of Foreign Affairs.' There is also another important department which should be mentioned—the *Censorate*—members of which exercise a supervision over the Boards, and, distributed

through the provinces, have it as their duty to memorialise the emperor on all subjects connected with the welfare of the people and the conduct of the government.

In the administration of the provinces, a governor-general and governor are for the most part associated as colleagues; though in Chih-li, Kan-sú, and Sze-ch'wan there is only the governor-general, and in Shan-hsi, Shan-tung, and Ho-nan only the governor. Below these two functionaries there are the lieutenant-governor (commonly called the treasurer), the provincial judge, the salt comptroller, and the grain-intendant. The provinces are further divided for the purposes of administration into *fú* or prefectures (amounting in all the provinces to 191), *cháu* or departments (in all, 58 independent of the *fú*, within which they are comprehended, and 155 subject to it), and *hsien* or districts, subject to the *fú* (in all 1288). There are also four *fú* occupied principally by the aboriginal peoples, twenty-eight *cháu* and four *hsien*. The rank of the different officials in these provinces is indicated by a knob or button on the top of their caps. In the two highest it is made of red coral; in the third it is clear blue; in the fourth, of *lapis lazuli*; in the fifth, of crystal; in the sixth, of an opaque white stone; and in the three lowest it is yellow, of gold or gilt. They also wear insignia or badges embroidered on a square patch, in the front or back of their robes, representing birds on the civilians and animals on the military officers.

As regards the *revenue* of the empire we need more information than we possess at present. Each province is required to support itself and to furnish a certain surplussage for the imperial government; but both the provinces and the court are constantly finding their income insufficient. Of the income of the several provinces for local purposes we cannot speak; but we take the following estimate of the *imperial revenue* from a series of carefully prepared articles contributed to the *China Mail* of Hong-kong in 1885:

	Tsals.
1. Land-tax portion, payable in silver.....	20,000,000
2. " " rice tribute to Peking at T.1.50 per pecul, and rice levy in provinces or money commutation.....	7,000,000
3. Salt Gabelle, and <i>likin</i> or transit duty on salt.....	9,500,000
4. Maritime customs under foreign supervision.....	13,000,000
5. Native customs, maritime and inland, and first inland levy on foreign opium.....	5,000,000
6. <i>Likin</i> on miscellaneous goods and opium, both foreign and native.....	9,500,000
Total.....	64,000,000

The *treel* at present has fallen to little more or even less than five shillings, but however we stretch its value we do not obtain the amount of £20,000,000; surely a very small imperial revenue for so great an empire with so vast a population. It has been increased at times by sales of office and by forced contributions, such as were once in England misnamed *benevolences*, both dangerous expedients; but the former was put a stop to by an edict in 1879. China had no foreign debt till 1874; in 1888 the foreign loans had amounted to about \$5,000,000.

The *imperial army* proper consists of Manchús, Mongols, and the descendants of Chinese who revolted from the Ming dynasty and joined the Manchús on their invasion of the empire, the first defection taking place in 1621. These are divided each into eight *corps* with different coloured banners, and as a whole are styled 'The Eight Banners.' Their headquarters are in Peking, and they are distributed in garrisons in most of the provinces, and also in Turkestan and I-li. Their number available for actual service amounts to nearly 350,000, of whom 100,000 are supposed to be

reviewed by the emperor at Peking once a year. In addition to this there is the *national army*, distributed in more than one thousand camps throughout the provinces, nearly twice as numerous as the imperial, and called 'The Army of the Green Standard,' being in fact little more than a vast militia or *gendarmérie*. These forces may in times of emergency be added to considerably by patriotic gentlemen calling out bands of 'braves,' effective enough to cope with insurgents, but all unfit to encounter the disciplined forces of any foreign power. Of this character at first were the troops of the T'ai-p'ing rebellion, which, till its suppression in 1867, for about twenty years proved a match for the imperial and national forces, and threatened the overthrow of the Manchû dynasty. See T'AI-P'INGS, and GORDON (CHARLES GEORGE). The navy is divided into a northern and a southern fleet—the former comprising four turret-ships, seven armoured rams, and twenty-three gunboats, besides torpedo boats; the latter, seven cruisers, sixteen gunboats (some of them armoured), besides floating batteries and torpedo boats. Most of the armoured ships have been built in Germany or in England, but several of the most powerful have been built in China.

Intercourse with Western Nations and Commerce.

—It was not till after the Cape of Good Hope was doubled, and the passage to India discovered by Vasco da Gama in 1497, that intercourse between any of the European nations and China was possible by sea. It was in 1516 that the Portuguese first made their appearance at Canton; and they were followed at intervals of time by the Spaniards, the Dutch, and the English in 1635. The Chinese received none of them cordially; and their dislike of them was increased by their mutual jealousies and collisions with one another. The Manchû sovereignty of the empire, moreover, was then in the throes of its birth, and its rulers were the more disposed to assert their own superiority to all other potentates. They would not acknowledge them as their equals, but only as their vassals. They felt the power of the foreigners whenever they made an attempt to restrict their operations by force, and began to fear them. As they became aware of their conquests in the Philippines, Java, and India, they would gladly have prohibited their approach to their territories altogether. In the meantime trade gradually increased, and there grew up the importation of *opium* (see OPIUM TRAFFIC) from India, and the wonderful eagerness of multitudes to purchase and smoke it. Before 1767 the import rarely exceeded 200 chests, but that year it amounted to 1000. In 1792 the British government wisely sent an embassy under Lord Macartney to Peking with presents to the emperor, to place the relations between the two countries on a secure and proper footing; but though the ambassador and members of his suite were courteously treated, the main objects were not accomplished. In 1800 an imperial edict expressly prohibited the importation of opium, and threatened all Chinese who smoked it with condign punishment. It had been before a smuggling traffic, and henceforth there could be no doubt of its real character. Still it went on, and increased from year to year. A second embassy from Great Britain in 1816 was dismissed from Peking suddenly and contumeliously because the ambassador would not perform the ceremony of *Sun kwei ch'ü k'au* ('the repeated prostrations'), and thereby acknowledge his own sovereign to be but a vassal of the empire.

So things went on till the charter of the East India Company expired in 1834, and the head of its factory was superseded by a representative of the sovereign of Great Britain who could not con-

duct his intercourse with the Hong merchants as the others had done. The two nations were brought defiantly face to face. On the one side was a resistless force, determined to prosecute its enterprise for the enlargement of its trade, and the conduct of it as with an equal nation; on the other side was the old empire seeming to be unconscious of its weakness, determined not to acknowledge the claim of equality, and confident of its power to suppress the import of opium. The government of China made its grand and final effort in 1839, and in the spring of that year the famous Lin Tsêh-hsiu was appointed to the governor-generalship of the Kwang provinces, and to bring the barbarians to reason. Out of his measures came our first war, which was declared by Great Britain against China in 1840. There could be no doubt as to the result in so unequal a contest; and we hurry to its close at Nanking, the old capital of the empire, where a treaty of peace was signed on the 29th August 1842 on board Her Majesty's ship *Cornwallis*. The principal articles were that the island of Hong-kong should be ceded to Great Britain; that the ports of Canton, Amoy and Fû-châu (in Fû-chien), Ning-po (in Cheh-chiang), and Shang-hai (in Chiang-sû) should be opened to British trade and residence; and that thereafter official correspondence should be conducted on terms of equality according to the standing of the parties. Nothing was said in the treaty on the subject of opium, the smuggling traffic in which went on as before.

Before fifteen years had passed away, because of troubles at Canton not all creditable to Great Britain, and the obstinacy of the governor-general Yeh Ming-chih in refusing to meet Sir John Bowring, it was thought necessary by the British government that war should be commenced against China again. In this undertaking France joined as our ally. Canton was taken on the 29th December 1857, when Yeh was captured and sent a prisoner to Calcutta. Canton being now in the possession of the allies, arrangements were made for its government by a joint commission; and in February 1858 the allied plenipotentiaries, accompanied by the commissioners of the United States and Russia as non-combatants, proceeded to the north to lay their demands before the emperor at Peking. There was not so much fighting as there had been in 1842, and on June 26 a second treaty was concluded at T'ien-tsin, renewing and confirming the former, but with many important additional stipulations, the most important of which were that the sovereigns of Great Britain and China might, if they saw fit, appoint ambassadors, ministers, or other diplomatic agents to their respective courts; and that the British representative should not be required to perform any ceremony derogatory to him as representing the sovereign of an independent nation on an equality with China. Other stipulations provided for the protection of Christian missionaries and their converts; for liberty for British subjects to travel, for their pleasure or for purposes of trade, under passports, into all parts of the interior of the country; for the opening of five additional ports for commerce—Niû-chwang (in Shing-king, the chief province of Manchuria), T'ang-châu (with port of Chefoo, in Shan-tung), T'ai-wan (Formosa, several ports), Ch'ao-châu (with port of Swa-t'au, in Kwang-tung), and Ch'ung (Kiung-châu, in Hái-nan)—and for authority for merchant-ships to trade on the Yang-tze River, ports on which would be opened when rebellion should have been put down and peace and order restored. (The river was not opened to steamer traffic till 1888.) Treaties on the same lines were concluded also with the United States, France, and Russia. A revision of the tariff regulations of 1842 was to take place subsequently in the year at

Shang-hai. This was done in October, and then opium was entered among the legitimate articles of import, and the arrangement confirmed that the government should employ a foreign official in the collection of all maritime duties. It might seem that these treaties secured everything which foreign nations could require, and that the humiliation of the Chinese government was complete. But they were nearly wrecked by one concluding stipulation in all of them but that of the United States, that the ratifications of them should be exchanged at Peking within a year. The emperor and his advisers, when the pressure of the force at T'ien-tsin was removed, could not bear the thought of the embassies entering the sacred capital, and foolishly cast about to escape from the condition. The forts at Ta-kü, guarding the entrance to the Pei-ho, and the approach to T'ien-tsin and thence to Peking, were rebuilt and strongly fortified. When the English, French, and American ministers returned to Shang-hai with the ratified treaties in 1859, the Chinese commissioners who had signed them at T'ien-tsin were waiting for them, and urged that the ratifications should be exchanged there. The French and English ministers then insisted on proceeding to Peking as the place nominated for the exchange. But when they arrived at the mouth of the river, with the gunboats under their command, they were unable to force the defences. A severe engagement ensued, and the allied forces sustained a repulse with heavy loss. It was the one victory gained by the Chinese. The British and French governments took immediate action. A third expedition under the same plenipotentiaries as before, with a force of nearly 20,000 men, was at the same place in little more than a year. The forts were taken on August 21, and on the 25th the plenipotentiaries were again established in T'ien-tsin. We can only refer to their march in September on Peking, with all its exciting details. The emperor (Hsien-fung) fled to Jeh-ho in the north of Chili-li, the imperial summer-retreat; and his brother, Prince Kung, whose name is well known, came to the front in the management of affairs. On the 13th October he surrendered the north-east gate of the city; and on the 24th the treaties were exchanged, and an additional convention signed, by which of course an additional indemnity was exacted from the Chinese, and an arrangement made about the emigration of coolies, which had become a crying scandal, while a small piece of the continent of the empire, lying opposite to Hong-kong, was ceded to that colony. So it was that the attempt of China to keep itself aloof from the rest of the world came to an end, and a new era in the history of the empire was initiated.

Hsien-fung died at Jeh-ho in August 1861, leaving the empire to his young son only six years old. A cabal at Jeh-ho tried to keep the boy in their possession, but his uncle, Prince Kung, succeeded in getting him to Peking, and along with the young emperor's mother and the empress-dowager, by whom Hsien-fung had had no child, loyally and successfully administered a regency in accordance with the new conditions of the government. The style of the reign was T'ung-chi, or 'Government in Union'; and on February 23, 1873, the emperor announced publicly, and specially to the foreign ministers, that he had taken the government into his own hands. This brought up the question of an audience, but, after a good deal of protocolling and negotiation, it was finally settled on June 29 by the emperor receiving all the ministers then in Peking without the ceremony of prostration. His reign did not last long, for he died in January 1875. As he left no son, and had designated no successor, the members of the im-

perial house, according to the rules in such a case, appointed as his successor Tsai-t'ien, the son of Prince Shun, a younger brother of Prince Kung. The new sovereign was a child of four years old, and began to reign under the style of Kwang Hsü, or 'The Illustrious Succession.' He assumed the government in March 1887.

Since the ratification of the treaties of T'ien-tsin, the ports on the Great Chiang, the opening of which was promised in them, have, with the exception of Nan-king, been opened—namely, Han-k'au (in Hù-peì), Chiü-chiang (Kiü-kiang, in Chiang-hsi), and Chin-chiang (Kin-kiang, in Chiang-sü). In addition to these, I-chang (in Hù-peì) and Wü-hü (in An-hui), also both on the Chiang, have been opened, with Wü-chü (in Cheli-chiang), and Pih-hai (Pak-hoi, in Kwang-tung), through the convention at Chefoo in 1876 between Sir Thomas F. Wade and Li Hung-chang. By the same convention certain concessions regarding the opium traffic were also stipulated for by the Chinese commissioner, and agreed to after various delays, with some modifications not unfavourable to the Chinese, by the British government.

According to the returns of trade and trade reports of the Imperial Maritime Customs for the year 1887, the vessels entered and cleared at the various treaty ports were 28,381, of which 14,337 were British. There were also among them 6402 vessels of foreign type, owned by Chinese, and sailing under the Chinese flag, and 1996 Chinese junks sailing under special licenses issued by the superintendents of customs at Shang-hai and Ning-po. The value of the whole trade, *net foreign and net native imports and exports*, was 246,172,053 *taels*. The revenue accruing from this immense trade (including import, export, and coast-trade duties, tonnage, and transit dues, and opium *li-kin*) was 20,541,997,402 *taels*, the average value of the *tael* during the year being 4s. 10½d. (having fallen from 5s. 8½d. in 1882).

The import of opium was 73,877 *piculs*, as against 67,801 in 1886. 'But it would be a mistake to assume that the demand for foreign opium increased in 1887. . . . The taste for it is languishing, a preference being given to the opium produced in Manchuria and some provinces of China Proper.'

The greatest increase of imports in 1887 was in cotton yarn. 'The yarn from Bombay is gradually taking the place of that from Manchester, it being a better wearing article.' Of the two principal exports of tea and silk, the quantities exported were rather less in 1887 than in 1886.

China has in the past been mainly a self-contained nation, but of late the Chinese have shown an increasing tendency to seek a livelihood abroad, especially in California, British Columbia, the Straits Settlements and Eastern Archipelago, and Australia. More than half the population of Singapore is Chinese; and in 1880 there were 200,000 Chinese in Java. In the Australian colonies there have never been more than 60,000. From 1855 to 1867 the immigration of Chinese into the United States varied from 3000 to 7000; from 1868 to 1881 it was usually between 10,000 and 20,000; in 1882 it was 33,614. But the imposition of prohibitory taxes on Chinese immigrants reduced this to 381 in 1883, and 17 in 1886. And in 1888 the immigration of Chinese workmen was absolutely forbidden for twenty-one years, though merchants and students with means are permitted to travel or reside in the Union. British Columbia and some of the Australian colonies have also sought to restrict Chinese immigration by imposing a heavy poll-tax on immigrant Chinese.

The government of the empire has in the meanwhile been on the whole eminently fortunate and successful. There is now peace within its borders and in its dependent territories. From

its hostilities with France about Annam, it came forth with more credit than in its former collisions with western powers, and the complications that might have arisen between it and Britain from the extension of the latter's eastern empire over Upper Burma were wisely arrested by the concession to it on the part of Lord Rosebery. It has its legations at the courts of Great Britain, France, Germany, Russia, and the United States. The advice of the foreign ministers at its court has been of important service to it in threatening emergencies. The collection of its maritime duties under foreign superintendence has materially added to its revenue. It has wisely employed the services of foreigners in its army and arsenals. Machinery for cotton manufacture and paper-making has been imported. Telegraphic communication has been established extensively between its different parts, and the making of railways is taken in hand. The government has commenced the proper training of its troops. It has acquired a considerable and powerful navy. It has founded schools and other institutions for the education of its young men in the knowledge of other languages, and in the various applications of western science. It has shown much sympathy with the sufferings of its people under unavoidable calamity. The one element of dissatisfaction with the present condition of China is the increasing growth of the poppy in its own provinces, and the increasing consumption of opium among the people. To set against this there is the accelerating diffusion of Christianity; nor is there reason to anticipate any but a great and good future for the empire.

CHINESE LANGUAGE, WRITING, AND LITERATURE.—The speech and the written composition of the Chinese differ more than those of any other people. The former addresses itself, like all other languages, to the mind through the ear; the latter speaks to the mind through the eye, not as words, but as symbols of ideas. All Chinese literature might be understood and translated though the student of it could not name a single character. The words and the names of the written characters are all monosyllabic, and are inconjugable and indeclinable, without inflection or change of any kind, and at the same time so versatile that there are few of them which may not perform the rôle indifferently, according to their position in a

sentence, of most of what we call Parts of Speech. That the speech has never advanced to anything like agglutination even (see PHILOLOGY), can be owing only to the early origin and cultivation of the written characters. These demand our chief attention.

The Chinese fathers spoke of course before they wrote, and when they had formed symbols to indicate their conceptions, they naturally called them by the names which they were accustomed to give to the objects of their perception and to their inward ideas. The time when they began to form those symbols cannot be exactly determined. Everywhere throughout China we find altars to Ts'ang Chieh, where paper with writing on it, often picked up from the ground, is burned in acknowledgment of his service to mankind as the inventor of written characters. Some authorities say that he was a sovereign prior to Fû Hsi; others that he was a minister of Hwang Ti, several centuries later. Fû Hsi's reign, according to the least unlikely of the chronological schemes, must be assigned to the 34th century B.C. We may safely say that the written characters of the Chinese existed, it may be in a rudimentary condition, more than 5000 years ago.

These characters are divided into six classes, according to the principle regulating their formation: (1) Pictorial characters (*Hsiang hsing*), being originally rude pictures of objects; (2) Indicative characters (*Chih shih*), intended by their form and the relation of their parts to suggest to the reader the idea in the mind of their makers; (3) Composite characters (*Hui i*), made up of two or more characters, the meanings of which blend in the meaning of the compound; (4) Inverted characters (*Chuan chü*), formed from others by the inversion of the whole, or of parts, of them; (5) Borrowed characters (*Chia tseh*), used in other than their proper signification; and (6) Phonetical characters (*Hsieh shang*), of which one part has a phonetic use, and indicates, exactly or approximately, the name of the compound, and the other part the category of meaning which it conveys.

The first three classes may be called *origines scripture Sinica*, but do not comprehend 2000 characters; the next two are unimportant. The sixth class is beyond comparison the most numerous, and embraces well on to 40,000 of the 43,000 characters, or thereabouts, found in the *K'ang-hsi* dictionary of 1704. The third class is the most interesting, bringing us mind to mind abreast of their framers, and showing us their ideas of the things represented by the characters. For example, a wife (called *fü*, 婦) is denoted by *nü*, 女, 'a female,' and *ch'au*, 帚, 'a broom:' she was the woman that used the broom. And, again, a male child (called *nan*, 男) is denoted by *t'ien*, 田, 'a field,' and *li*, 力, 'strength:' his birth was welcomed as new strength for the work of the field.

The phonetical characters arose from the impossibility of framing a sufficient number of characters on the other five principles of formation to serve the purpose of a written medium. A certain number of characters, which has varied from 554 to 214 (employed in the dictionaries of the last and present dynasties), were set apart as 'ideograms' or 'mothers of meaning,' and a larger and more indefinite number were chosen, which in connection with them might express the name or sound of the compounds, and be called 'mothers of sound.' Their number altogether is large, but many are derivatives of others, and not a few of the ideograms themselves are among them. Dr Chalmers, of

Hong-kong, published in 1878 a 'Concise Chinese Dictionary' in which the phonetic constituents are reduced to 884. These, with the 214 ideograms, having been learned, 1098 characters in all, the student has mastered the elements of all the Chinese characters. Pronunciation is constantly varying, and his reading will often be far from giving 'the present truth' of the names of many characters; but a knowledge of these phonetic constituents does much to lighten the strain upon the memory in learning Chinese.

The monosyllabic utterances, however, available to name the 43,000 characters are few indeed. In Pekinese they are only 426. Even if there were as many as 1000 different syllables in the language, equally divided among the characters, more than forty meanings would belong to each. In the 'Syllabic Dictionary' of the late Dr Williams, containing only 12,527 characters, placed under 552 syllables, there are about 150 characters placed under the monosyllable *t* (= *cc* in *see*). To the eye there is no difficulty in distinguishing all these *t*'s; but to the ear such discrimination, unassisted otherwise, is impossible. To assist it, there is a system of *tones*, the number of which varies in different dialects. According to the tone in which the monosyllable is pronounced, its meaning is different; and this renders what we call a 'good ear' desirable in learning the speech of China. There are other devices by which the difficulty occasioned by the slender syllabary of Chinese speech is overcome, such as the combination of synonyms, and the multiplication of particles hardly to be found in the dictionaries. As a consequence, while conciseness is a characteristic of good Chinese composition, the spoken language is verbose—e.g. the fable of 'The Fox and the Grapes,' told in 131 English words, is rendered in good Chinese by 85 characters, while a version of it in Cantonese colloquial contains 163 words. Still the colloquial speech is not difficult of acquisition. The writer had often occasion to remark that the children of English families resident in China, who were not restricted from intercourse with the Chinese, spoke the colloquial more fluently and readily than the English which was spoken by their parents.

After the Buddhist missionaries came to China, and scholars got some acquaintance with the use of the Sanskrit alphabet, they began to devise a method of spelling (so to speak) their characters, dividing each monosyllable into an initial and a final sound, and then joining two other characters together, one to give the initial, and the other, always in the same tone as the character thus spelled, to give its final sound. This method, though cumbersome, might have been of use to the student if the same characters had always been employed for the same initial and the same final sounds, as in Chalmers's 'Concise Dictionary.' But every lexicographer adopted his own characters at his pleasure

—e.g. the character 理 (*l* = *l* + *i*) is spelled in one dictionary by 良 (*l*-iang) and 止 (*ch* + *i*); in a second by 兩 (*l*-iang) and 耳 (*érh*, anciently called *i*); and in a third by 良 (*l*-iang) and 以 (*i*). The K'ang-hsi lexicon, after reciting these three spellings, adds that the sound is the same as 里, which is the phonetic element, *li*. This spelling only distracts the student; the Chinese scholars failed to apprehend the nature of the alphabetic signs or letters.

From the analysis of the characters which has been given, their inconjugable and indeclinable character, and their versatility such that one of them may perform the rôle of most of our 'parts of

speech,' it is evident that the attempt to apply to them the categories and rules of grammar on the model of our Aryan languages must be very much 'love's labour lost;' yet composition with them has its own rules, which are not difficult to learn. As Dr Marshman expressed it in his grammar of 1814, 'the whole of Chinese grammar depends on position.' Under the skilful application of this principle, the Chinese characters weave the web of thought with the rapidity of engine-driven shuttles; and there has grown up an immense Chinese literature.

Before entering on a brief description of that literature, a paragraph may be allowed to what is called 'pidgin English,' a sort of *lingua franca*, which grew up between Chinese on the seaboard and foreigners, for the purpose of intercommunication, while neither party had the means or the wish to acquire an accurate knowledge of the language of the other. 'Pidgin' is a Chinese attempt to pronounce our word 'business;' and the materials of the lingo are nearly all English words similarly represented or misrepresented, and called 'broken English.' The idiom, on the other hand, is entirely that of colloquial Chinese. Foreigners get to master it in a short time, so as to carry on long conversations by means of it, and to transact important affairs of business. Dr Williams (vol. i. p. 832) gives the following example of it, taken from the *Chinese Repository*, vol. x.: A gentleman meets a Chinese acquaintance, accompanying a coffin which is being conveyed along the street, and asks him who is dead ('who hab die?'). 'No man hab catches die,' is the answer. 'This one piecy collin I just now give my olo fader. He likee too much counta my numba one plover; s'pose he someteem catches die, can usee he.'—'So fashion, eh? How muchee plice (price) can catches one alla same same?'—'I tinky can get one alla same so fashion one tousan dolla, so; this hab first chop hansom, lo!' There is often a charming raciness about such conversations, and one occasionally sees in his Chinese interlocutor the working of the mind which has been described in the formation of the third or composite class of characters. For instance, a Chinese boy (all servants are called *boys*) once came to ask the writer to intercede for him with his master, who was treating him, he thought, unjustly. 'He one sarcee (saucy = bad) man,' he said; 'he no hab topside pidgin;' meaning that his master had no *religion*, no dealing with the powers above. This jargon is passing away. Chinese who know English, and English who know Chinese, are increasing from year to year. See C. G. Leland's *Pidgin-English Sing-song* (1876).

How vast and varied the Chinese literature is may be seen from a very brief and imperfect analysis of the contents of the catalogue *raisonné* of the works collected by an order of the K'ien-lung reign in 1722, to be printed or reprinted as a great national library. The catalogue is arranged in four divisions under the name of *K'ü*, 'Arsenals,' or 'Magazines': the first, in 44 chapters, containing works on the classics and dictionaries necessary in the study of them; the second, in 46 chapters, works of history; the third, in 57 chapters, works on philosophy and the arts; and the fourth, in 53 chapters, works of poetry and belles-lettres.

The *classics* are the Confucian books, and a few others, on which an amount of commentary has been expended certainly not inferior either in voluminousness or in patient care to what has been put forth on our sacred Scriptures; and it still goes on without abatement. A collection of books on them by a multitude of scholars of the present dynasty was published at Canton in 1829 in 1400 chapters. The *historics* are

those of China itself, and are divided into four classes according to the different methods of the authors. The first place is given to the 'Correct' and 'Authoritative,' or the 'Dynastic,' which now form a collection of twenty-four different works. The writer's own copy of it, bound in English fashion, amounts to sixty-four thick volumes, imperial 8vo size. In general, each dynastic history contains an account of the several reigns, followed by treatises on chronology, rites, music, jurisprudence, food and goods or political economy, state sacrifices, astronomy, the five elements, geography, and especially topography, and the literature. After these treatises we have a host of biographies of the most remarkable individuals of the dynasty; and the history concludes with an account of the foreign peoples with which there has been any intercourse. These notices of the dynastic histories only occupy two of the 46 chapters of the division. Among the subdivisions are three chapters on 'Books on the Constitution,' embracing such works as Ma Twan-lin's *General Examination of Records and Scholars*, said by Rémusat to be 'a library in itself,' and the two continuations of it, each as voluminous as itself; and the *Penal Code* of the present dynasty, of which we have the translation by Sir G. T. Staunton, published in 1810.

The *philosophy and arts* division deals with the works of the class of the literati, both orthodox and heterodox; of writers on military affairs; on legislation; on agriculture, horticulture, and the mulberry-tree; on medicine; on astronomy and mathematics; on divination; on painting, music, engraving, and other arts; on ink and inkstones; on tea and the tea-plant; on articles of diet; on the works of several of the Roman Catholic missionaries; and concludes with works of Taoism and Buddhism. Five chapters are devoted to works on mythology and lighter subjects, not including, however, as we shall presently see, novels and romances.

The *belles-lettres* division has the general name of *Tsi*, 'Collections' or 'Compilations.' It comprehends the various classes of polite literature, poetry, and analytical or critical works. Chinese poetry has no epic; but it is rich in ballads, lyrical and descriptive pieces, rhythmical effusions and songs, eulogies and elegies, and monumental inscriptions. Its poets have been without number, and its poetesses not a few. One of the Confucian classics is 'The Book of Poetry;' and poetry is one of the standing subjects in the competitive examinations.

Novels and romances, dramas, and books written in the colloquial style are not admitted into such grand catalogues as the above; but the literature is not without them. There is no more pleasant reading than some of their historical romances, such as the *Expanded Narrative of the Period of the Three Kingdoms* (168-245 A.D.), by a raconteur of extraordinarily graphic power, written in our 13th century. Some of the best novels have been translated into European languages: *The Fortunate Union*, by Sir John Francis Davis; *The Rambles of the Chang-Teh Emperor in Kiang-nan*, under the superintendence of the present writer; *Les Deux Cousins* and *Les Deux Jeunes Filles Lettrées*, by the late Stanislas Julien; and others, as well as some of the dramas.

Great as the Chinese literature is, it would have been greater, especially in the earlier portions of it, but for the burning of the Confucian books by the founder of the Ts'in dynasty, and for the subsequent 'bibliothecal catastrophes' which overtook one imperial library after another down to the middle of our 6th century. Paper was made and employed for writing in our first century, and

printing by means of wooden blocks, according to the fashion still prevailing, was soon practised. An edition of all the classical books was so published in 922 A.D. The invention of movable types belongs to a blacksmith called Pi Shing less than a century afterwards, though such types are only now beginning to supersede the wooden blocks. Some of the inventions claimed for China have been called in question, but about this—perhaps the most important of all inventions after the alphabet—there can be no dispute.

See Prémare's *Notitia Linguae Sinicæ* (Malacca, 1831); Rémusat's *Eléments de la Grammaire Chinoise* (Paris, 1822); Marshman's *Clavis Sinica*; Julien's *Syntaxe Nouvelle de la Langue Chinoise* (Paris, 1869-70); Gabelentz's *Chinesische Grammatik* (Leip. 1881); Edkins's *Grammar of the Chinese Colloquial Language, commonly called the Mandarin Dialect* (Shanghai, 1864); Chalmers's *Structure of Chinese Characters* (Aberdeen, 1882); the *Dictionaries of Morrison, Medhurst, Williams, Chalmers, and others*; Wylie's *Notes on Chinese Literature* (Shanghai, 1867); Legge's *Chinese Classics*, and volumes iii. xvi. xxvii. and xxviii. of the *Sacred Books of the East*; Biot's *Le Tcheou Li, ou Rites des Tcheou* (Paris, 1851); and Zottoli's *Cursus Litteraturæ Sinicæ* (Shanghai, 1879).

China, or CHINA-WARE. See POTTERY.

China Bark, a name of Cinchona (q.v.) Bark, often to be met in books, and in common use on the Continent. It is derived, not from the empire of China, but from *Kina* or *Quina*, the Peruvian name of cinchona.

China Clay. See KAOLIN.

China Grass, or CHINESE GRASS. See BERMERIA, GRASS-CLOTH.

China Ink. See INK.

Chinandega, the capital of a department of Nicaragua, Central America, 30 miles NW. of Leon by rail, and 13 by rail from the Pacific coast. It has considerable trade, and about 8000 inhabitants.—OLD CHINANDEGA, 5 miles to the N., has a pop. of 4000.

China Root, the dry tuberous *rhizome* or root-stock of *Smilax China*, a climbing shrubby plant, closely allied to sarsaparilla; a native of China, Cochinchina, and Japan (see SARSAPARILLA and SMILACEÆ). It was formerly held in high medical repute in Europe, but is now disused; in China, however, it retains its reputation, especially in rheumatic or syphilitic cases. Various American species have been from time to time introduced as substitutes.

China Sea, the portion of the Pacific Ocean to the east of China and Siam, extending, in the widest application of the term, from Corea to Borneo. This extensive body of water falls into three divisions: the Yellow Sea (Chinese, *Whang-hai*), between Corea and North China, with the gulfs of Pechili and Leaotong, and Corea Bay; the Eastern China Sea (*Tung-hai*), from about 32° N. lat. to the Tropic of Cancer; and the South China Sea (*Nan-hai*), from Formosa to Borneo, with the Philippines on the east, and forming the great gulfs of Tonquin and Siam. Many geographers limit the term to this last division. See ASIA; and for the twin dangers, typhoons and pirates, that have combined to render the navigation of these waters notoriously perilous, see separate articles under these heads.

Chincha Islands, three bare, rocky islets, with a joint area of 6½ miles, rising 200 feet out of the sea off the coast of Peru, opposite the Bay of Pisco. From 1841 till 1874 they yielded millions of tons of Guano (q.v.); but the beds, originally some 100 feet thick, became exhausted.

Chinchay-cocha, a lake of Peru, in the department of Junin, 13,330 feet above the sea, is 36 miles long and 7 broad, with an area of about

300 sq. m. It is the source of the river Jauga, and abounds in fish and wild-fowl.

Chinchilla, a town of Spain, 12 miles SE. of Albacete by rail, situated on an abrupt rocky hill, in which are numerous caves that serve as dwelling-places. It has gypsum and marble quarries and manufactures of earthenware. Pop. 6080.

Chinchilla (*C. lanigera*), a South American rodent, well known by its soft gray fur. Two related animals (*Lagidium peruanum* and *Lagotomus trichodactylus*, the Viscacha) form along with the true chinchilla the small family Chinchillidæ in the porcupine section of the Rodent order. All the three are somewhat squirrel-like animals, but have long hind-legs, bushy tail, very soft fur, and complete collar-bones. The chinchilla and the lagidium occur on the higher Andes

Chinchilla.

of Peru and Chili at a high elevation; the viscacha is found on the Pampas. The three genera differ distinctly, but not widely. The chinchilla proper has a body about a foot long, and the tail measures fully 6 inches. They are extremely active animals, and climb among the rocks with the greatest agility. They are killed in thousands for the sake of their fur, and prolific as they are, seem to be diminishing in abundance. The fur is used for various articles of attire, and the Peruvians are said to have formerly woven the hair into fine fabrics. See VISCACHA.

Chinchon, a town of Spain, 25 miles SE. of Madrid. Pop. 4771. After a Countess of Chinchon, wife of the governor of Peru in 1638, Peruvian bark was named *Chinchona*, now habitually misspelled *Cinchona* (q.v.).

Chindwa'ra, chief town of a district in the Central Provinces of India, on a plateau 2200 feet above the sea, 70 miles N. by W. of Nagpur. It is the seat of a Free Church mission. Pop. 8220. —The district has an area of 3915 sq. m., and a pop. (1881) of 372,899.

Chinese Hemp, a kind of *Corchorus* (q.v.).

Chinese White, a permanent white pigment used in the arts, consists of the white oxide of zinc, ZnO. Its manufacture was first attempted in 1780, and in 1796 Atkinson patented its use as a substitute for white lead, which had previously been the only available white pigment, and was a most unsatisfactory one on account of its turning brown on continued exposure to the atmosphere. Only, however, in 1844 was a good and cheap method of preparing the pigment discovered by M. Leclaire.

Chingalpat (*Chengalpat*), a town of India, 36 miles SW. of Madras by rail, with district court and hospital, a public bungalow, and an old fort, now abandoned, but formerly of great strength and importance as a key of Madras. Clive captured it in 1752. Pop. (1881) 5617. —The district to which

the town gives name has an area of 2842 sq. m., and a pop. (1881) of 981,381, mostly Hindus. It is a flat country, cut up by canals. The soil is poor. With 115 miles of coast, it has not a single harbour or anything like shelter from the surf. Recently, plantations of *Casuarina* (q.v.) have been made on the wide sand-dunes along the coast, for the supply of firewood to Madras.

Chini, a village of the Punjab, 1 mile from the Sutlej's right bank, on the southern slope of a lofty mountain, 9085 feet above sea-level. It was a favourite hill residence of Lord Dalhousie.

Chin-Kiang, a Chinese port on the Yang-tze-kiang, in the province of Keang-su, 40 miles ENE. of Nanking. Formerly, as the southern key of the neighbouring Grand Canal, it was both an important stronghold and a centre of traffic; but it was bombarded by the British in 1842, and nearly destroyed by the Tái-pings in 1853. Opened to foreign trade in 1861, the commerce of the place has not greatly increased since, unless in the import of opium. Pop. 135,000.

Chinon, an antique town in the French department of Indre-et-Loire, beautifully situated on the Vienne, 31 miles SW. of Tours by rail. Crowning a lofty rock are the ruins of its vast old castle, the 'French Windsor' of the Plantagenets, the death-place of Henry II.; and later the residence of several French sovereigns, where, in 1429, Joan of Arc revealed her mission to the Dauphin. A farmhouse across the Vienne is pointed out as Rabelais' birthplace. Pop. 4397.

Chinooks, a tribe of Indians, now nearly extinct, on the Columbia River on the west coast of North America. Their language was very difficult to learn and to pronounce, and this led to the formation of the *Chinook jargon*, a trader's *lingua Franca*, consisting of words from French and English as well as Chinook and other Indian languages. Gibbs published a dictionary of it at New York in 1863.

Chin'sura, a town on the right bank of the Húgli, originally Dutch, but ceded to the British in 1825, and now included in Húgli (q.v.).

Chintz, a highly glazed printed calico, with a pattern generally in several colours on a white or light-coloured ground. It was chiefly used for bed-hangings, for covering furniture, and other purposes where there is much exposure to dust, which does not adhere to its highly calendered surface. In Great Britain chintz is now mostly employed for babies' bassinets. It has been long the practice in Persia to have the pattern on some chintzes partly in gold. Glue or other size is printed on the cloth, to which the gold dust or leaf adheres. See CRETONNE.

Chiococca, a genus of *Cinchonaceæ*, of which two species in particular, *C. unguifuga* and *C. densifolia*, the former a trailing herb, the latter a bushy shrub, enjoy a high reputation in Brazil as cures for snake-bites and in the treatment of dyspepsia. An infusion of the root is one of the most violent emetic and drastic medicines known, but it is happily no longer used in Europe.

Chioggia, or CHIOZZA, an important seaport town of Northern Italy, 15 miles SSW. of Venice, on an island at the southern end of the Venetian Lagoon, connected with the mainland by a stone bridge of 43 arches. It is founded on piles, and has a cathedral; its harbour, the deepest in the Lagoon, is guarded by forts and batteries. Pop., inclusive of Sottomarina, (1881) 25,084, chiefly engaged in the coasting trade, lace-making, weaving, shipbuilding, and fishing.

Chios (now called by the natives *Chio*, Italianised into *Scio*) is one of the most beautiful and

fertile islands in the Aegean Sea, belonging to Turkey, 7 miles off the coast of Asia Minor, at the entrance to the Gulf of Smyrna; about 30 miles long from north to south, by 8 to 15 miles broad, with a coast-line of about 110 miles, an area of 320 sq. m., and a pop. of about 70,000, almost all Greeks. The larger northern part is more mountainous than the southern. The climate is delightful and salubrious. Earthquakes are, however, not rare, and one in 1881 caused the death of 3558 persons, and the destruction of property to the value of three to four millions sterling. The wine produced on the north-west coast, the *Vinum Arvisium* of ancient times, is still esteemed. Other products are figs, also noted in classical days; mastic, silk, lemons, oranges, and olives. Goats' skins are also exported. The capital, Chios, about the middle of the east coast, contains about 13,000 inhabitants, and has a haven touched by various services of steamers, and doing a good trade. On the west coast is a rich monastery, Nea-Moni, founded in the 11th century. In ancient times excellent marble and potters' clay were quarried in the mountains, and recently pits of antimony and ochre are worked.

Chios is one of the places which contended for the honour of giving birth to Homer. It formed in early times one of the most flourishing of the Ionian States, and contributed 100 ships to the Greek force defeated by the Persians in the sea-fight off Miletus (494 B.C.). After the Persian victory the town and temples of Chios were burnt and many of the people enslaved. In more recent times the island was taken by the Genoese (1346), and by the Turks (1566), in whose hands it has since, except for a short interval, remained. It was conferred as private property on the sultana. After a long period of prosperity, Chios suffered a terrible blow during the war of Greek independence. A number of the Chiotas having in 1821 joined the revolted Samians, a Turkish fleet and army in 1822 inflicted dreadful vengeance; 25,000 Chiotas fell by the sword, 47,000 were sold into slavery, and only some 5000 escaped. A second rising in 1827 was likewise unsuccessful. The island has since been gradually recovering.

Chip Hats. See BRAZILIAN GRASS.

Chipmunk (*Tamias striatus*), a kind of squirrel, common in North America. The genus includes only a few species, often called Ground Squirrels, and distinguished from the common *Sciurus* by the possession of capacious cheek-pouches, by the longer snout but shorter tail and ears, by the constant absence of the first upper molars. They are pretty little animals, of active

Chipmunk (*Tamias striatus*).

disposition, living in underground burrows, where they indulge to apparent excess their mania for

storing food. The food consists of nuts, seeds, and grain; and the chipmunks plunder to no inconsiderable extent the fields of wheat and maize. They are, like many other rodents, very prolific, and keep up their population in spite of heavy mortality in severe winters and from the attacks of boys, carnivores, and birds of prey. *Tamias asiaticus*, another American species, also occurs along the north-east of Europe and Asia. See SQUIRREL.

Chippenham, a municipal borough in Wiltshire, on the Avon, here crossed by a bridge of twenty-two arches, 13 miles N.E. of Bath. An ancient place, it was captured by the Danes from Alfred the Great in 878, and now consists chiefly of a long well-built street. It has a trade in cheese and other agricultural produce, but its cloth manufactures have declined. It lost its last parliamentary member in 1885. Pop. (1841) 1875; (1881) 1352.

Chippeway Indians (written also *Chippewa*, *Ojchipee*, and *Ojibbeway*), a numerous tribe of American Indians, belonging to the Algonquin stock, and now settled on a reservation in northern Minnesota, and in various districts of Canada.

Chipping Norton, a small municipal borough in the North of Oxfordshire, 85 miles N.W. of London by rail, with woollen, tweed, and glove manufactures. Pop. (1881) 4167.

Chipping Wycombe. See WYCOMBE.

Chiquichiqui Palm (*Leopoldinia Piassaba*), the Piassaba of the north of Brazil, and one of the palms which yield the Piassaba (q.v.) fibre so much used for making brushes.

Chiquimula, a small town (pop. 6000) in the east of Guatemala, which gives name to a province, and to the ISTHMUS OF CHIQUIMULA, with a breadth from the Gulf of Honduras to the Pacific of about 150 miles.

Chiquinquirá, the largest town in the department of Boyacá, Colombia, near the Suarez, 30 miles W. of Tunja, was an Indian place of pilgrimage before the conquest; and the Spaniards having found here a miraculous image of the Virgin, the church where this is preserved is now visited by some 60,000 pilgrims annually. Pop. 18,000.

Chiquitos, or NAQUINOÑES ('men'), an Indian stem of Bolivia, dwelling between the Paraguay and the Madeira. Bronze-coloured and well built, with large, round heads, low foreheads, and small bright eyes, they are cheerful, hospitable, fond of music and dancing, but of a low morality, and live (about 20,000 in all) in villages formerly founded by the Jesuits.

Chirata, or CHIRETTA (*Ophelia Chirata*), an officinal plant belonging to the order Gentianæ. It is a native of the mountains of the north of India. The whole plant is intensely bitter, and has been long used in its native country as a tonic and stomachic, as also by European practitioners in India as a febrifuge.

Chiriquí, an administrative division of the department of Panama, Colombia, adjoining Costa Rica. Area, 6500 sq. m.; pop. 43,000. It is well wooded, and has rich pasturage, especially on the Atlantic coast, where the climate is very moist. The Cordilleras that occupy the interior reach their highest point in the volcano of Chiriquí (11,265 feet). Chief town, David.—On the north coast is a spacious lagoon of the same name, with a depth of water for the largest ships, which receives an unimportant Rio Chiriquí.

Chiromancy. See PALMISTRY.

Chí'ron, or CHEIRON, the most famous of the Centaurs (q.v.), son of Cronos and Philyra, and husband of Nais or Chariclo. He lived on Mount Pelion, and was famous for his skill in healing.

hunting, music, and prophecy. The great Achilles and other heroes were his pupils. He died by being accidentally wounded by one of the poisoned arrows of his friend Hercules.

Chiroptera. See BAT.

Chiru, or *PANTHALOPS* (*Antelope hodgsoni*), a species of antelope, inhabiting the pine-forests and elevated open plains of Tibet, in regions bordering on the snow-line. It is much larger than the chamois, being about five feet in length, and three feet high at the shoulder. The colour is reddish-fawn with some black. The chiru lives in great herds, and seems to exceed almost all the other gregarious ruminants in watchfulness against the approach of danger. They are said often to lie concealed in holes which they make for themselves among the stones.

Chislehurst, a village in Kent, 11 miles SE. of London. Sir Nicholas Bacon was a native. Camden Park estate (now built over) was the residence of Camden the antiquary. Napoleon III. died at Camden Place in 1873; his remains along with those of the Prince Imperial were removed to Farnborough in January 1888. There are an Orphanage and a Governesses' Benevolent Institution here.

Chiswick, a suburban parish of Middlesex, on the north bank of the Thames, $7\frac{1}{2}$ miles W. by S. of St Paul's. Here are some charming old river-side houses (one of them William Morris's home); here too are extensive market-gardens to supply London, and the gardens of the Horticultural Society. In the churchyard are Hogarth's grave and Foscolo's cenotaph; and at the Duke of Devonshire's beautiful villa, Chiswick House, died Fox and Canning. Pop. (1861) 6505; (1881) 15,975. See an article in *Harper's* for August 1888.

Chitaldrug, the chief town of Chitaldrug district, Mysore, India, 126 miles NW. of Bangalore, with manufactures of coarse blankets and cotton cloth. The military cantonments have been abandoned on account of their unhealthiness. Pop. (1881) 4271.—The district is the least populous in the Mysore State, in which it is distinguished for its low rainfall (10 to 25 inches) and arid, stony soil. Area, 4871 sq. m. Pop. (1871) 531,360; (1881) 376,310—the decrease being due to the famine of 1876–78.

Chitin, the substance which forms most of the hard parts of jointed-footed animals (arthropods), such as crustaceans, insects, and spiders. It was discovered by Odier in 1823, but regarded erroneously as free from nitrogen; rediscovered by Lassaigne in 1843; and since then recognised in all the four chief classes of arthropods and in some other types. Huxley has given an account of its formation in the crayfish. Chitin has been demonstrated in many arthropods, also in the pen of cuttle-fishes (*Mollusca*), and in the stalk and shell of *Lingula anatina*, a brachiopod. Its presence is at least probable in many other cases. In arthropods it is not confined to forming the firm and often very hard exoskeleton, but occurs internally in supporting plates, &c. among the tissues. In the crayfish it seems even to form the sheath of the strong ventral nerves. In arthropods the greater portion of the gut is formed as an intucking of the outer skin (ectoderm) from in front and behind, and the resulting portions known as fore- and hind-gut are also lined by this chitin, which frequently exhibit special internal thickenings for food-grinding purposes. The chitinous coating or cuticle is formed from underlying skin cells. In some cases the epidermic cells probably sweat it off after the manner of other secretions; but Huxley has shown in regard to the crayfish that the superficial portion

of the cells undergoes a chitinous modification, being literally turned into chitin. The outer coat of crustacea is hardened by the addition of calcium carbonate or phosphate, especially the former; such calcareous hardening is very rare in insects, but copper has been demonstrated in some beetle cuticles.

Chitin is an amorphous white substance. It contains nitrogen, but is free from sulphur. Its resistance to acids and alkalis is very great; it is unaffected by digestive ferments, by water, hot or cold, by alcohol or ether. It may be dissolved by strong mineral acids (hydrochloric or sulphuric), and prepared from the cleaned exoskeleton of a lobster, or better still from the pen of a squid. Chemically it is regarded as a derivative of carbohydrates, and may be split up into sugar and glycosamin. According to Ledderhose, its formula is $C_{12}H_{20}N_2O_{10}$; according to Sundwik, $C_{60}H_{100}N_8O_{38} + nH_2O$. See Krukenberg, *Vergleichend-physiologische Vorträge* (1886).

Chiton, a genus of marine molluscs, type of an important sub-class which may be regarded as introductory to gastropods. Unlike the lop-sided snails, the chitons are bilaterally symmetrical. The head is at the anterior end, the anus posterior; the 'foot' occupies the whole of the ventral surface; the heart, the gills, the excretory tubes, the genital ducts, all exhibit the same symmetry. This marked contrast to the gastropods proper is further supported by the disposition of the two important nerve cords (pedal and visceral) which run parallel to one another along the body. In some forms there are numerous eyes, which occur, however, not on the head, but on the body. Another striking feature is the presence of a series of eight shell-plates along the back. On these and other grounds the chitons are separated from gastropods proper, and established as a separate order, on which the

Chiton elegans.

name *Polyplacophora*, alluding to the multiple shell-plates, has been bestowed. Nor is the order a small one. Of the genus *Chiton* alone over 400 species have been recorded, and other smaller genera are also distinguished. The British species are small; those from warmer climates sometimes measure 3 to 4 inches in length. They are undoubtedly representatives of a primitive type, and include numerous fossil forms from the Silurian onwards. They are not, however, the simplest gastropods, for a few other forms, known it is true with less fullness, exhibit the same essential features in even simpler expression. These are (a) the *Neomenia*, including the genera *Neomenia* and *Proneomenia*, and (b) the single genus *Chæto-*derma. The systematic import of these last forms has been emphasised by Professor Hubrecht (*Quart. Jour. Micr. Sci.* 1882). Along with the chitons they

are usually gathered together into a special subclass or class styled *Isopleura* or *Amphineura*, names referring to the equal-sided symmetry and to the double parallel nerve-cords. See GASTEROPODS; Haddon, *Challenger Report*, xv. (1886); Moseley, *Quart. Jour. Micr. Sci.* xxv. (1886).

Chitrál, a small state under the supremacy of Cashmere, in the upper basin of the Kunar, or *Kashkar*, a tributary of the Kabul River, and on the borders of Kafiristan. It is 5200 feet above sea-level. Major Biddulph, the first European to enter it, has described it in his *Tribes of the Hindoo Koosh* (Calcutta, 1880). *

Chittagong, or ISLAMABAD ('residence of the faithful,' a name conferred by the Moguls, who captured it in 1665), a port of Bengal, 220 miles E. of Calcutta, on the eastern side of the Bay of Bengal, and on the Karnaphuli River, about 12 miles from its mouth. The town is very scattered, built entirely on a number of small, steep hills, and is notorious for the prevalence of malaria. Formerly an important centre of trade under the Portuguese, with one of the best ports in India, it has recently regained much of the commerce it lost with the rise of Calcutta; and in the year 1881-82 its trade was larger than ever before, the inland imports and exports being valued at £612,692, and the sea-borne trade at £1,886,346. The principal imports are salt and European goods, the chief exports rice, tea, and jute. Pop. (1881) 20,969.—The district of the same name, of which the town is the capital, is a long narrow strip of country lying between the Bay of Bengal and the hill tracts of Chittagong and Arakan, with an area of 2567 sq. m., and a pop. (1881) of 1,132,341, two-thirds Mohammedans. Most of the local traffic is by the rivers and numerous canals or creeks, the latter being one of the causes of the unhealthiness of the district, in which cholera is endemic, and every form of malarious disease constantly at work.—Chittagong also gives name to a *division*—area, 12,118 sq. m.; pop. (1881) 3,574,048—and to the hill district to the east—area, 5419 sq. m.; pop. 101,597, three-fourths Buddhists—from whose forests a large proportion of the government elephants are obtained.

Chittagong Wood, a name somewhat vaguely used by cabinetmakers, is usually the wood of *Chickrassia tubularis*, a tree of the order Cedrelaceæ, a native of the mountainous countries to the east of Bengal. In some parts of India it is called *Cedar* or *Bastard Cedar*, names, however, which are also given to other kinds of wood. It is much valued in India, and is used like mahogany; it is often beautifully veined and mottled.

Chittim, or KITTIM, in the Old Testament, is usually identified with Cyprus. See also HITTITES.

Chittor ('little town'), a town of India, the headquarters of North Arcot district, on the Poini, 100 miles W. of Madras. Pop. 5809.

Chiusa, the name of several places in Italy, the largest being CHIUSA SCLAFANI, a town of Sicily, 31 miles SSW. of Palermo, with oil, fruit, and sumach cultivation. Pop. 6874.

Chiusi, a town of Central Italy, 102 miles NNW. of Rome by rail, with a population of 1824, stands on an olive-clad eminence in the Val di Chiana, not far from the small Lago di Chiusi. In ancient times, under the name of *Clusium*, it was one of the twelve republics of Etruria, and the residence of Porsenna (q.v.). When Italy was overrun by the barbarians, it fell into decay, the whole valley was depopulated, and became the pestilential pool described by Dante. Since the improvement of the course of the Chiana (q.v.), Chiusi has begun to flourish again along with the whole district. But it is in connection with the discovery of

Etruscan antiquities that the place is chiefly heard of. Within this century immense quantities of these remains have been found in the neighbourhood in the grottoes that served the ancient Etruscans as tombs. They consist chiefly of sun-dried black earthenware vases, ornaments, reliefs, and carved stonework, and are preserved in the museums at Chiusi and Florence. See Liverani, *Le Catacombe di Chiusi* (1872).

Chivalry (Fr. *chevalerie*, from *chevalier*, 'a horse-man'), a social arrangement of medieval life in Christian Europe, of which knighthood formed a central feature. It included everything relating to martial accomplishments, and the relation between vassal and lord, then the chief bond of society. With regard to the position of the female sex and domestic life, it developed sentiments and manners which had a powerful and salutary effect on modern society, although it is true that the high ideal standard of purity of morals which it cultivated was not always fully exemplified in the lives of those who were trained under its influence.* Though closely connected with feudalism, its germ has by some writers been traced to a much earlier age; and analogies have been pointed out between the doctrines of Boethius's *Consolations of Philosophy* and the ideas contained in the *Testament of Love*. See FEUDAL SYSTEM, KNIGHT.

In English Law, Chivalry is used to mean the tenure of lands by Knight's Service, which might be general or special, according as the tenant was bound to perform to the King or superior military service generally, or some particular service.

The COURT OF CHIVALRY was a military court established by Edward III., of which the Earl Marshal and the Lord High Constable were judges. It tried military offences, and decided questions of personal honour, questions as to coat-armour and the like; and sat for the last time in 1737.

Chivasso, a town of Northern Italy, on the Po, 18 miles NE. of Turin by rail, with trade in cattle and corn. Its fortifications were destroyed in 1804 by the French. Pop. 4375.

Chive, or CIVE (*Allium schanoprasum*), a plant of the same genus with the leek and onion (see ALLIUM), a perennial, $\frac{1}{2}$ to 1 foot in height, with very small, flat, clustered bulbs, increasing by its bulbs so as to form dense tufts. The leaves are tubular, cylindrical-tapering, radical, nearly as long as the almost leafless flowering-stem, which is terminated by a hemispherical, many-flowered, not bulbiferous umbel of bluish red, or, more rarely, flesh-coloured flowers. The stamens are included within the perianth. This rather pretty little plant grows wild on the banks of rivers, in marshy or occasionally flooded places, and in rocky pastures in the middle latitudes of Europe and Asia, as also in the far north of North America. It is a rare native of Britain, being only recorded with certainty from some localities in Cornwall and Northumberland. In some of the mountainous districts of Europe a variety is found, larger and stronger in all its parts, and with flowering-stems more leafy. Chives—the name is generally used in the plural—are commonly cultivated in kitchen-gardens, often as an edging for plots, and are used for flavouring soups and dishes, and in salads. Their properties are very similar to those of the onion. The part used is the young leaves, which bear repeated cuttings in the season. The bulbs also are by some used in preference to onions for pickling, their flavour being considered more delicate. For this purpose the clumps of bulbs are broken up in autumn or early winter, and planted in well-manured ground, in lines four or five inches apart, but standing almost close in line. In this way they become larger and more succulent by the following autumn,

when they are lifted for use, the largest only being taken, and the smaller replanted for a future crop.

Chizerots and Burins form one of those peculiar races in France that live isolated in the midst of the rest of the population, and are despised and hated by their neighbours. They are found in the arrondissement of Bourg-en-Bresse, in the department of Ain; and the communes of Sermoyer, Arbigny, Boz, and Ozan belong to them. According to tradition, they are descended from the Saracens. Although industrious and prosperous, they are held in the utmost contempt and detestation by their peasant neighbours, often themselves indolent and destitute. They are looked upon as covetous and malicious, and scarcely would the daughter of a small farmer or well-to-do day-labourer become the wife of one of them, so that they mostly marry among themselves. From time immemorial, they have been field-labourers, cattle-dealers, butchers, and the like. Many of them are very good-looking, the young women in particular being handsome and clear-complexioned, with large black eyes. See Michel, *Histoire des Races Maudites de la France et de l'Espagne* (2 vols. Paris, 1847).

Chladni, ERNST FLORENS FRIEDRICH, founder of the science of acoustics, was born at Wittenberg, November 30, 1756. He studied law in his native place, and also in Leipzig, where, in 1782, he was made Doctor of Laws. Chladni ultimately abandoned juridical studies altogether, devoted his mind to natural science, and being acquainted with music, was led to observe that the laws of sound were by no means so well established as those of other branches of physics. He therefore began to apply his knowledge of mathematics and physics to acoustics, and travelled for ten years (after 1802) through Germany, Holland, France, Italy, Russia, and Denmark, giving lectures on the subject, which were very successful. He died in Breslau, April 4, 1827. Chladni's writings include works on the theory of sound (1787), and on acoustics (1802 and 1817), on meteors (1820), and on the improving of musical instruments. There is a Life by Melde (1866). See SOUND.

Chlamydo-phorus, a rare and peculiar mammal of the sloth and ant-eater order (Edentata); in its general features resembling the Armadillos, but unique in the character of its skin armour.

Pichiciago (*Chlamydo-phorus truncatus*).

The head and trunk are covered by about twenty movable cross bands of quadrangular horny (slightly bony) plates. These form an overhanging dorsal shield, attached to the body only along the middle line of the back. The hind parts are protected by the abrupt occurrence of a strong upright bony shield attached to the hip-girdle. The short tail, which is broadened out into a trowel shape, and tucked in between the legs, is protected by horny plates, as are also the dorsal portions of the short, clawed limbs. The rest of the body is covered with

long silky hair. There are 8 teeth on each side above, and 8-9 below. The eyes and ears are inconspicuous. *C. truncatus* (the Pichiciago) is a burrowing animal, living 'in the sandy plains of the western part of the Argentine Republic.' During the day it keeps to its burrow, and is little known. It is 5 or 6 inches in length, with white hair and pinkish scales. *C. retusa*, from Bolivia, is larger, and the dorsal shield has a wider attachment to the body. See ANT-EATER, ARMADILLO, EDENTATA, SLOTH.

Chlamydosaurus, the Frilled Lizard of Australia, is a lizard with an extraordinary frilled membrane attached to the hinder part of the head, neck, and chest, and covering its shoulders. This lies in plaits when at rest, but is expanded when the animal, which may be three feet long, is irritated or frightened. It is akin to the Iguanidae.

Chlamys, a short light mantle, worn as an outer garment by ancient Greek youths, and sometimes adopted, even at an early period, by particular Romans, as by L. Scipio and Sulla. A common way of arranging it was to pass one of its shorter sides round the neck, fastening the two corners with a clasp or buckle, and allowing the longer part to hang down behind as far as the knees.

Chlopicki, JOSEPH, a Polish soldier and patriot, was born in Galicia in 1771. Entering the army early, he took part in the first insurrection of the Poles, next entered the French service, and served with great credit under Napoleon in Italy, at Eylau and Friedland, in Spain, and next at Smolensk and Moskwa. After the taking of Paris by the allies in 1814, he led back to Poland the remains of the Polish troops who had fought under Bonaparte, and was well received by the Emperor Alexander, who made him a general of division. When the second insurrection of the Poles broke out in 1830, Chlopicki, who foresaw the hopeless nature of the attempt, was forced against his will to be dictator, but after six weeks of contentious opposition from the hot-headed and rashly extreme patriotic party, he resigned his office. But with a heroism all the more heroic that he knew too well the cause was hopeless, he re-entered the Polish army as a simple soldier, and fought with reckless bravery at Wawre and Grochow. Severely wounded in one engagement, he retired to Cracow, where he died 30th September 1854. (The name is pronounced *Chlopitzki*.)

Chloral (*trichloraldehyde*) is a limpid, colourless, oily liquid, with a peculiar penetrating odour, and is formed when anhydrous alcohol is acted on by dry chlorine gas. It dissolves sulphur, phosphorus, bromine, and iodine, and is closely allied to Aldehyde (q.v.). Chloral combined with one equivalent of water forms chloral hydrate, a white crystalline substance, with a pungent odour and a bitter taste, to which the name chloral is commonly though incorrectly applied. Chloral was discovered by Liebig in 1831, and investigated by Dumas; the chloral hydrate was first used as an anæsthetic and hypnotic by Liebreich in 1869. The chief action of a moderate dose of chloral (15 to 30 grains) is the production of sleep, closely resembling natural sleep, and usually sound and refreshing. It has also a marked effect in quieting excitement, as in insanity or delirium; and in relaxing spasm, and checking convulsions and allied conditions. Its action as an anæsthetic is very capricious and uncertain; medicinal doses sometimes relieve pain completely, but much more often fail to do so. It lessens the force of the heart's action, and in large doses greatly reduces the temperature of the body; and to these effects the fatal results that sometimes follow its administration are chiefly due. As a

hypnotic it is most valuable in cases where opium or morphia is dangerous or undesirable (in children, in disease of the kidneys), and where sleeplessness is combined with excitement (delirium of fevers, delirium tremens, insanity); but it may be employed in many other cases with advantage. In tetanus (lockjaw), and other diseases attended by convulsions, it is often of great value. It acts as an antidote in poisoning by strychnia and Calabar bean. It must be employed with the greatest caution, or not at all where there is any reason to suspect weakness of the heart, or embarrassment of the circulation from any other cause; in such cases dangerous symptoms are very readily produced by it. When habitually employed to procure sleep, it is generally less hurtful than opium; but sometimes 'profound melancholy and enfeeblement of the will, muscular lassitude, inability to sleep without the drug,' and other untoward symptoms (called collectively *chloralism*) result, and only disappear when its use is discontinued. Moreover, fatal accidents from its indiscriminate use are far from uncommon. Poisoning by chloral should be treated by keeping the patient warm, attempting to rouse him, administering coffee and small doses of strychnia or atropia.

When chloral hydrate is treated with caustic potash, pure chloroform is obtained; but owing to the expense, this process has not come into use in Great Britain. It has been supposed that its anæsthetic property is the result of a similar formation of chloroform in the blood, but no evidence of this is forthcoming.

Chloranthaceæ, a small group, chiefly tropical, allied to the peppers, aromatic and stimulant. *Chloranthus inconspicuus* is the Chu-lan of the Chinese, who use it for perfuming teas.

Chloric Acid, HClO_3 , is the acid corresponding to the hypothetical oxide of chlorine, represented by the formula Cl_2O_5 . It is a syrupy liquid, with faint chlorine odour and acid reaction. A piece of paper dipped into it becomes charred and takes fire, and it is instantly decomposed by contact with organic matter. In itself it is not of much importance, but it forms a class of salts called *chlorates*, one of which at least is well known. *Chlorate of potash*, KClO_3 , is an article of commercial value, and may be prepared by passing chlorine into a solution of caustic potash, heating the liquid, and crystallising out the salt. It forms pearly plates, which, when heated, melt and give off oxygen in abundance. So also when thrown on red-hot charcoal, oxygen is given off, and violent deflagration ensues. On account of this property it is used in the preparation of coloured fires, but its use is not unattended with danger, owing to their tendency to spontaneous combustion and its explosive properties when triturated with sulphur. Mixed cautiously with amorphous phosphorus, previously moistened with alcohol, it forms a mixture which, when dry, explodes if tapped with a pencil. This mixture is employed in the manufacture of some kinds of matches, which give a slight explosion when struck. If a crystal of chlorate of potash be placed on a piece of paper saturated with turpentine, and a drop of sulphuric acid added, it causes the inflaming of the turpentine with explosive rapidity. The chlorate is also used in medicine, and in a compressed form has become a popular remedy in certain forms of sore throat.

Chlorimetry is the process of estimating the proportion of 'available chlorine' in Bleaching Powder (q.v.), which may vary from 20 to 40 per cent. The term *available* applies only to that portion of the chlorine which is easily liberated, and which takes part in the bleaching process.

Chlorine, which is present as chloride, as in chloride of calcium, CaCl_2 , has no bleaching power, and is not estimated by chlorimetry.

The process is one of volumetric analysis, and the apparatus used is similar to that described in the article on Analysis (q.v.). There are several practical methods of chlorimetry, all based on the principle of measuring the oxidising power of the bleaching powder. This is arrived at by making a solution containing a definite amount of pure sulphate of iron, arsenious acid, or other substance capable of being oxidised, running in the solution of bleaching powder very slowly, and then by suitable tests determining the exact point when oxidation has taken place. By calculation the amount of 'available chlorine' is at once obtained. Where substances other than bleaching powder are under examination, slight modifications of the process may be necessary.

Chlorine (sym. Cl; atom. wt. 35.5; Gr. *chlōros*, 'pale green') is a non-metallic element discovered by Scheele in 1774, and named by him *æthiologisticated marine air*. Afterwards, in 1810, Davy proved it to be an elementary body, and gave it the name which it now bears. In nature it is always found in a state of combination. United with sodium, Na, it occurs very largely as the chloride of sodium, NaCl —common salt—in the ocean; in large beds, as rock-salt; in all natural waters, including even rain-water; in clays, soils, limestone; in volcanic incrustations; and in the vegetable and animal kingdoms. The preparation of gaseous chlorine by its liberation, directly or indirectly, from common salt, has been fully described under BLEACHING POWDER, which is the form in which chlorine is prepared and employed commercially. For experimental purposes the gas may be received in jars filled with warm water at the pneumatic trough, when the chlorine rises into the jar, and displaces the water. When thus obtained it is a yellowish-green gas with a peculiar and suffocating odour, is not combustible, and is a very feeble supporter of ordinary combustion. A lighted candle placed in it burns with a very smoky flame, owing to the hydrogen of the oil alone burning, while the carbon is liberated. Several of the metals, such as antimony, copper, and arsenic, in a fine state of division, or in the condition of thin leaves, at once become red hot, and burn when introduced into the gas. A piece of thin paper soaked in turpentine likewise bursts into flame. Chlorine is a very heavy gas, nearly $2\frac{1}{2}$ times heavier than air, its specific gravity being 2.470 (air = 1.000); it is soluble in cold water to the extent of two volumes of chlorine in one of water, and yields a solution resembling the gas in colour, odour, and other properties. The principal properties of chlorine are those of a bleacher of cotton and linen (see BLEACHING) and a most powerful Disinfectant (q.v.). The gas can be condensed by pressure and cold into a transparent dark greenish-yellow limpid liquid, with a specific gravity of 1.330 (water = 1.000), which also possesses bleaching properties and a most powerful odour. On the animal system chlorine acts, in very minute quantity, by producing a sensation of warmth in the respiratory passages, and increasing the expectoration; in large quantity, by causing spasm of the glottis, violent cough, and a feeling of suffocation. The workmen in chemical manufactories, who get accustomed to the chlorine in small quantities, are generally stout—at least, lay on fat—but complain of acidity in the stomach, which they correct by taking chalk, and also suffer from the corrosion of their teeth, which are eaten away to stumps. The antidotes to the evil effects of the introduction of chlorine into the lungs are the inhalation of the vapour of water, alcohol, ether, or chloroform; but

the latter two should never be resorted to except under medical supervision.

Chlorine forms with other substances a very large number of chemical compounds. Mixed with hydrogen in equal volumes, and exposed to sunlight or flame, union takes place with explosive energy, and hydrochloric acid, HCl , is produced. This acid forms an extensive class of salts called *chlorides* (see HYDROCHLORIC ACID), but many of these may be produced by the direct combination of chlorine with the metals, as in the experiments described above. Chlorine replaces other elements or groups of atoms in organic compounds, forming chloro-derivatives. In combination with carbon and hydrogen it forms many substances, among which Chloroform (q.v.) is perhaps chief. Chlorine forms with oxygen a series of oxygen acids—viz. Hypochlorous, HClO ; Chlorous, HClO_2 ; Chloric, HClO_3 ; and Perchloric Acid, HClO_4 ; the more important of which are referred to under separate heads.

Chlorite (Gr. *chloros*, 'green'), or RIPIDOLITE, an abundant mineral, consisting of silica, alumina, magnesia, and protoxide of iron, in somewhat variable proportions. It is of a green colour, and occurs now and again crystallised in minute hexagonal plates, or in aggregates of small leaflets, either singly or disposed in radial groups, which are scattered over the joint-surfaces of certain rocks, or may occur in a thin incrustation upon other minerals. It is rather soft, and is easily broken or scratched with a knife. Before the blowpipe it is with difficulty fused on thin edges. It is readily distinguished from talc by yielding water in a closed tube. There are several other minerals included with ripidolite under the 'chlorite group' which are with difficulty distinguished from ripidolite and from each other. Chlorite enters largely into the formation of certain schistose rocks (e.g. Chlorite-schist, q.v.), and is common as a decomposition-product after such minerals as mica, augite, hornblende, and garnet.

Chlorite-schist, a green schistose rock, in which chlorite is abundant in foliated plates, usually blended with minute grains of quartz, and often with felspar, mica, talc, or magnetite.

Chloritic Marl, a thin bed of white or pale-yellow marl, sometimes indurated, containing dark-green glauconitic grains, phosphatic nodules, and iron pyrites. It belongs to the Cretaceous system, coming between the Upper Greensand and Chalk Marl. It is characterised by the abundance of *Scaphites aequalis*, a species of ammonites. It is confined to the southern districts of England occupied by the Cretaceous rocks.

Chlorodyne is a patent medicine of considerable popularity, invented by Dr James Collis Browne (1819-84), but largely imitated by various chemists. It contains opium, chloroform, prussic acid, and probably Indian hemp, and is flavoured with sugar and peppermint. As it is apt to separate into two liquids on standing, it should never be taken unless it has previously been well shaken; and as, in taking a dose of chlorodyne, the patient swallows an unknown quantity of three or four of the deadliest poisons with which we are acquainted, it is always advisable to begin with small doses. It is unquestionably a compound which sometimes succeeds in allaying pain and inducing sleep when opiates have failed; but whether a physician is justified in recommending a remedy with the composition of which he is unacquainted is a doubtful question. To meet this difficulty the Medical Council, in the 1885 edition of the British Pharmacopœia, have introduced the tincture of chloroform and morphia, which practically represents chlorodyne. Five to fifteen drops is the average dose.

Chloroform, CHCl_3 , was discovered as a chemical curiosity about the same time (1831) by Guthrie in America, Liebig in Germany, and Soubeiran in France. Soon, however, its properties as a stimulant when taken internally attracted attention, and when in 1847 it was brought into prominent notice as an anæsthetic by Sir James Simpson, it was at once recognised as one of the most valuable contributions of chemical science to suffering humanity. See ANÆSTHESIA.

Chloroform is composed of 12 parts of carbon, 1 part of hydrogen, and 106½ parts of chlorine. It may be produced in several ways, but in this country at least the process by which it is obtained from bleaching powder is the only one adopted on the large scale. The materials employed are bleaching powder, alcohol, and water. The bleaching powder and water are mixed together to form a thin cream, the alcohol added, and the whole placed in a capacious still, connected with suitable condensing apparatus. On the application of heat the contents rapidly froth up, and even though the external application of heat be stopped, the chemical action is so violent that the chloroform distils over rapidly along with water and any excess of alcohol. As so obtained it is very impure, and requires to be carefully treated with sulphuric acid, and then redistilled before it is fit for anæsthetic purposes. Pure chloroform is a limpid, mobile, colourless, volatile liquid, with a characteristic odour, and a powerful sweetish taste. When diluted with alcohol it enters into the composition of artificial fruit-essences, to which it gives a flavour akin to that of ripe apples. It is a very heavy liquid, its specific gravity being about 1·500 (water = 1·000), and as it does not readily mix with or dissolve in water, it falls to the bottom when poured into a vessel of that liquid, forming a distinct layer. Chloroform is readily miscible with alcohol and ether, and it dissolves camphor, amber, gutta-percha, wax, black and red sealing-wax, iodine, and bromine, as well as strychnine and other alkaloids. It dissolves a small proportion of water, being also slightly soluble in that liquid. Chloroform is not combustible in the ordinary sense of the term, but when its vapour is brought in contact with flame it burns, imparting a green tint to it, and irritating fumes are produced. Pure chloroform is not met with in commerce owing to the readiness with which it decomposes when exposed to light. In order to prevent this a small proportion of alcohol is added, the specific gravity being thus reduced from 1·500 to 1·497. When evaporated on the hand no disagreeable odour should be noticeable, and when shaken with sulphuric acid only a very slight discoloration of the acid (due to the small proportion of alcohol) should result. Besides its anæsthetic properties, which are elsewhere discussed (see ANÆSTHESIA), chloroform is used in medicine both externally and internally. When applied to the skin or any of the mucous membranes it acts as a powerful irritant, producing a burning sensation, and on this account it is of value as an application in rheumatism, lumbago, and neuralgia. As an application to a decayed tooth its action is twofold, as a stimulant and counter-irritant locally, and also to a partial extent as an anæsthetic. Taken internally, diluted with alcohol, it is a powerful stimulant, and readily produces a species of intoxication. It is by some habitually taken as a narcotic luxury. As chloric ether, a product distilled from bleaching powder, and containing chloroform, it enters into the composition of cough mixtures, pick-me-ups, &c.

Chlorophyll, as its name implies, is leaf-green, the ordinary colouring matter of vegetation. Microscopic examination of plant tissues shows it some-

times to tinge the whole protoplasm of the cell (though never the cell sap). Much more generally, however, it is collected into definite bodies, the so-called chlorophyll granules, or less frequently, as in some of the lower algae, arranged in starlike masses (*Zygnema*) or spiral bands (*Spirogyra*). A brief immersion of the specimen in alcohol suffices to dissolve out the chlorophyll, and leave the form of the chlorophyll bodies unaltered; and the solution may then be conveniently studied in a fresh state, as it gradually fades on keeping. It is of a deep rich green by transmitted, but of characteristic deep red colour by reflected light; in a word, is highly fluorescent. The absorption-spectrum is quite characteristic; yet the complex nature of the substance is strongly argued for on the ground of the following experiment. Shake up the alcoholic solution with benzol, and when the two fluids have had time to separate, we find the green to have disappeared. The lighter alcohol above is now of a strongly yellow hue, while the subjacent benzol is of a distinctly bluish green. To these colouring matters the names *Xanthophyll* and *Cyanophyll* are commonly given. While their separate spectra are quite characteristic, their combined spectrum seems to restore that of chlorophyll. The latter substance resembles the blue-green colouring matter of some of the lowest algae (*Oscillatoria*, &c.), while the yellow substance recalls that of many buds and flowers. Others, however, maintain that these substances are really the result of a destructive decomposition of true chlorophyll; while Gautier has even prepared green needle-like crystals which he regards as chlorophyll in a pure state. The chemical composition of chlorophyll is also a matter of considerable difficulty, both on account of its own easy decomposability, and its being necessarily accompanied by other extractive substances; thus the question of the presence or absence of iron has been much debated, a matter which seems to indicate variability of composition. This is further borne out by the labours of spectroscopists. Thus in addition to the familiar well-defined analogous colouring matters which characterise respectively the blue-green alga, the brown and the red (see SEAWEEDES), researches such as those of Sorby and others seem to indicate a number of varieties too numerous even for enumeration. This varietal range, however, may best be approached after considering the conditions in which chlorophyll is formed. Of the chemical factors little can be said save that the presence of iron in the soil seems to be quite indispensable; the physical conditions are, however, simpler.

A sufficient temperature is necessary to the formation of chlorophyll; for seedlings from 4° to 8° C. being a minimum, while the process is said to take place most rapidly, on the average, at about 35° C. The most important condition is, however, the presence of light; with rare exceptions, plants cannot form any chlorophyll in darkness. The blanching of celery or leeks is a familiar instance of this, or conversely, the green coating acquired by a potato-tuber where it happens to have been denuded of its covering of earth. Shoots formed in darkness form colouring matter indeed, but only of a pale-yellow hue, the so-called *etioline*; after a very brief exposure to light, especially if direct sunshine, chlorophyll appears, apparently by direct transformation of the former. The other colouring matters of plants are sometimes in protoplasmic granules (chromoplasts), but more frequently also in solution in the sap; and these frequently are present in such abundance, especially in the epidermis, &c., as to mask the chlorophyll altogether, as happens especially in so many of our hothouse plants with decorative leaves. The general tendency of research is to indicate that all the phenomena of plant colour

seem intimately connected with what we may term the general life-history of chlorophyll. Thus the yellows and reds of young shoots and leaves in spring may be interpreted as having some relation to the development of chlorophyll, if not absolutely stages of the process; while the same suggestion arises with regard to the colouring matters of flowers, which are similarly to be regarded as imperfectly vegetative shoots, although in this case through the onset of the reproductive function, instead of merely by reason of immaturity. Finally also with regard to the autumnal hues, in which the chlorophyll pigment seems to be disintegrating through colour-stages analogous to those of its evolution in spring, or of its arrestment in the flower. In favour of such a view evidence is forthcoming from either end of the vegetable kingdom. Thus Cienkowski has shown that in the case of certain unicellular algae, which like the common *Protococcus* of rain-water, possess red pigment as well as green when passing into the resting stage, the quantity of red may be increased in proportion as autumnal conditions are reproduced by artificially lowering the temperature, and *vice versa*. The same experiment may be made with the common *Sempervivums*, *Sedums*, &c., whose leaves become more or less red in autumn or winter; those of *Thuja* (*Arbor Vitæ*) similarly become brownish, but recover themselves in spring. Among almost all cultivated plants, *variegated* varieties tend to arise, that is to say, we have certain cell-areas of the leaf-parenchyma destitute of chlorophyll. The conditions of this are obscure (see VARIEGATED PLANTS); but it is noteworthy that this loss of chlorophyll may also take place in lower plants, so that there is considerable ground for regarding at least many apparent fungi as simply algae which have degenerated in this respect through parasitism. Phanerogamous parasites like *Toothwort* (q.v.) or *Dodder* (q.v.) similarly become almost completely blanched.

Chlorophyll apparently identical with that of green parts of plants, can be experimentally demonstrated in the tissues of certain animals; and although this has in many cases been shown to be due to the presence of symbiotic algae (see SYMBIOSIS), there remain cases—e.g. *Hydra viridis*, &c., and at the very least *Paramacium viride*, in which we have undeniably intrinsic chlorophyll, and this of truly vegetable function.

The development of our knowledge with respect to the functions of chlorophyll is still far from complete, and may in any case be more conveniently treated under LEAF and VEGETABLE PHYSIOLOGY (q.v.); suffice it therefore to state here the elementary and essential fact that its presence is in every case constantly associated with the process of *assimilation*, or elaboration of new products by help of the energy of sunlight, upon which the continued nutrition of the green plant depends; and of which the formation of starch with decomposition of carbonic anhydride and disengagement of oxygen are the most obvious chemical results. A fuller account of the state of knowledge and opinion upon this portion of the subject will be found in the articles referred to.

Chlorops. See CORN FLY.

Chlorosis (Gr. *chlōros*, 'pale green'), a peculiar form of anæmia or bloodlessness, common in young women, and connected with the disorders incident to the critical period of life. It has been called the *green sickness*, from the peculiar dingy greenish-yellow hue of the complexion; the green colour, however, is not always present. The disease is attended with very great debility, and often with breathlessness, palpitation, and other distressing or even alarming symptoms. In a few cases it is

associated with imperfect development of the larger arteries, and is then incurable; but in the vast majority of cases it yields readily to treatment unless complicated with some other disease. The principal means to be employed are air, exercise, often salt-water baths, with a nutritious and rather stimulating diet, and purgatives if required; together with such special remedies as are adapted for restoring deficient secretions, and bringing the entire female system of organs into a natural condition; but above all, large doses of iron, continued for some weeks or months. The tendency to chlorosis is often hereditary, and relapses are very apt to take place. For Chlorosis in plants, see PLANTS (DISEASES OF).

Choate, RUFUS, a scholarly American lawyer, born in Essex, Massachusetts, 1st October 1799, graduated at Dartmouth in 1819, and was admitted to the bar in 1823. He sat in congress from 1830 to 1834, when he settled in Boston. Here his singular eloquence rapidly advanced him to the place of leader of the Massachusetts bar; indeed, it has been claimed for him that he was the most eminent advocate New England, or even America, has produced. After a term in the United States senate, 1841-45, he returned to his profession; in 1859, his health giving way, he sailed for Europe, but stopped at Halifax, Nova Scotia, where he died July 13. His writings, with a memoir, were published at Boston in 1862. See Neilson's *Memories of Rufus Choate* (Boston, 1884).

Chocolate is a preparation of the seeds of *Theobroma Cacao* (see COCOA), made by grinding the seeds mixed with water to a very fine paste. The mill is usually constructed of heavy metal rollers turning in a circular course upon a flat metal plate. A curved knife or scoop is attached to the rollers in such-wise that it shall return the paste continually to be crushed and recrushed by the rollers until it becomes almost impalpable. The object of this is to render the nut, otherwise difficult of solution, readily diffusible in water or milk when used as a beverage. The paste when unmixed, or mixed only with flour or other farinaceous material, is usually called *Cocoa*, but when much sugar or spices such as vanilla, cinnamon, &c. are added, it bears the name of *Chocolate*. The two names are much confounded commercially. *Chocolate* is moulded into cakes or sold in powder or flakes formed by simply drying the paste as it comes from the mill. The seeds or nuts contain a large proportion (30 to 50 per cent.) of oily matter (*cocoa butter*). This may be partially removed or all retained in the chocolate. In the latter case much of it is mechanically adherent to the sugar or farinaceous matter. *Chocolate* is a favourite beverage in Spain, Italy, and other southern countries, especially for breakfast; the cake or powder is heated and diffused in water or milk with much stirring. The Italian rarely uses butter, but cuts his bread into sippets and dips them in his chocolate, the oily matter of which performs the same nutritive functions as the butter we spread on our bread. It is sometimes mixed with coffee in Italy, and there known as *mischiata*. It is also made into a paste with cream and sugar and frozen as chocolate ice. Vanilla is the favourite flavouring. The name appears to be Mexican, *Chocolatl* (*choco*, 'cocoa,' and *latl*, 'water'). It was introduced from America to Europe by the Spaniards. It is highly nutritious, containing a large proportion of nitrogenous flesh-forming material. On this account it is used as portable food by many mountaineers. An excessively rich food is obtained by preparing it with milk and then whisking in a raw egg. The waiters at certain Italian coffee-houses call this

la gloria, and the ordinary infusion 'Aurora.' In the solid form, mixed with much sugar, cream, and various confections, chocolate is largely used as a sweetmeat, and is introduced in pastry.

Chocolate Root. See GUM.

Choctaws, a tribe of American Indians, belonging to the Appalachian stock, and formerly inhabiting the central portions of Mississippi, but now settled in the south-east of Indian Territory, where they are regarded as one of the four civilised nations, and hold 6,668,000 acres of land. They have benefited greatly by the labours of missionaries, and have become good farmers and mechanics.

Chodowiecki, DANIEL NIKOLAUS, German painter and copperplate engraver, was born in 1726 at Danzig, and died director of the Academy of Sciences at Berlin, 7th February 1801. He produced some 3000 plates, mostly small.

Choir. See CHURCH and CHANCEL.

Choirs and Choral Singing. Choir properly denotes the body of singers who perform the musical part of a church service, but has lately been applied also to independent choral societies, such as the Bach Choir in London. The composition of a choir is so variable that only a few general principles can be indicated. The commonest and typical form is that of the four-part choir of mixed voices—i.e. both male and female; the soprano part, however, is often taken by boys, and the next by male alto voices. While it is desirable that the individual voices should themselves be good and well trained, there are requisites over and above those looked for in solo singing. These are briefly: (1) An equal balance of voice-power in each part; (2) adaptation of the number of voices to the size of the building where they sing; (3) an exact sense of time and rhythm in the singers, and the power of maintaining each part independent, while still in agreement with the others; (4) facility in singing at sight; and (5) frequent practice together. Though many choirs are guided by the organist alone, or have merely a leader, a conductor is always of the greatest advantage, much of the expression and effect depending on him, and the more so in proportion as the choir and the works sung are larger. It is a much debated point whether the choir should sing alone, or guide the singing of the congregation. In not a few American churches the former principle is developed in a singular form, the quartet choir consisting merely of four solo singers, by whom alone the whole music of the service is sung.

In the Eastern Church the music is unaccompanied, and is sung by the priest and choir alone. The choir of the Imperial Chapel in St Petersburg consists of about 120 voices, men and boys, who have no other occupation. In the Church of Rome the most notable is the Sistine or papal choir in Rome. Its genealogy is traceable to the singing schools established by very early popes, but extensively developed by Gregory the Great. It has for a long while consisted of thirty-two choral chaplains, occasionally supplemented, and has generally possessed specimens of the rare adult male soprano voice, the leader in 1888 being one. They sing unaccompanied, but the organ is generally used in other Roman Catholic services. The effect of their singing during the Passion-week has been well described in Mendelssohn's letters. A body of some thirty-five of them were brought by the pope to the coronation of Napoleon in Notre Dame, Paris, and entirely eclipsed a large chorus accompanied by eighty harps which was expected to produce an unprecedented effect. Since 1870 this choir has been very seldom heard at all. In the Lutheran churches in Germany, when there is a

choir, as a rule they sing alone, and the congregation alone. The choir sing (unaccompanied) polyphonic motets, or less familiar hymns, the congregation singing the chorales in unison, with organ accompaniment. The most celebrated German choirs are those of the cathedral in Berlin and of the Thomas Church at Leipzig. The English cathedral choirs are more or less richly endowed, Durham standing at the head with £2400 a year. As a specimen, some details may be given in regard to Norwich. Here the choir consists of fourteen choristers (boys) and eight lay clerks (men). For the purpose of antiphonal singing these are divided into two sides, denominated (from the seats of the precentor and dean respectively) the *Cantoris* and *Decani*. The lay clerks are appointed by the dean; the choristers are trained by the organist, and have two rehearsals daily. A full rehearsal of all the choir is held weekly; they all attend on Sundays and festivals and (with the exception that each lay clerk is entitled to one week's absence in six) at the daily services. The precentor has the whole control of the choir, selection of music, &c., while the organist is responsible for the accompaniments, the training of the choristers, &c. The late Dr Buck of Norwich was perhaps the most celebrated trainer of cathedral choirs in the 19th century. Among the noted English choirs are those of the Temple Church in London and Magdalen and New College Chapels, Oxford. There is almost no literature on this subject, but much information is contained in Curwen's *Studies in Worship Music* (two series, Lond. 1885-88). See CHORUS.

Choiseul-Amboise, ÉTIENNE FRANÇOIS, DUC DE, minister of Louis XV., was born in 1719. He served with credit in the Austrian Wars of Succession, and through the favour of the king's mistress, Madame de Pompadour, became lieutenant-general in 1748, and Duc de Choiseul in 1758. He was sent to Rome and next to Vienna in 1756 to arrange the alliance between France and Austria against Frederick the Great, and it was his policy that brought about later the family league of the Bourbon monarchs in Europe. He made himself very popular by the fairly favourable terms he obtained in 1763 at the close of a disastrous war, and further by his opposition to the Jesuits. He conceived, and almost carried out, a plan for the formal emancipation of the Gallican Church from papal influence, improved the army and navy, developed the trade and industry both of the nation and of the colonies, and opened up anew an intercourse with India, whose native princes were assisted by French officers in their endeavours to expel the British from the peninsula. He had spies in every European court, and so ruled all diplomatic and political cabals as to deserve the title the Empress of Russia gave him, *Le Cocher de l'Europe*. His power had survived the death of his patroness in 1764, but the rise of Madame Dubarry, who succeeded Madame de Pompadour in the king's affections, gradually alienated Louis from his able minister, who retired in 1770 to his magnificent estate of Chanteloup, where he lived in princely splendour. After the accession of Louis XVI. he received permission to return to Paris, and was often consulted, but never recovered his official position. He died May 7, 1785.

Choke-cherry, a name given to certain nearly allied species of Cherry (q.v.), natives of North America, having small fruit in racemes, like the Bird-cherry or Cherry-laurel (q.v.), from which latter, however, they are easily distinguished by their deciduous leaves. The fruit is at first rather agreeable, but afterwards astringent in the mouth. The species and varieties are not easily definable,

but *Prunus (Cerasus) virginiana*, *serotina*, and *borealis* may be especially mentioned. The bark is used as a febrifuge and tonic, under the name of *Wild Cherry Bark*; and by distilling it with water, a volatile oil is obtained from it, associated with hydrocyanic acid, called *Oil of Wild Cherry*.

Choke-damp, also called *after-damp* or *foul-damp*, is the carbonic acid gas given off by coal which accumulates in coal-mines, and may suffocate those exposed to it. It is distinguished from *fire-damp*, the marsh-gas or light carburetted hydrogen which causes the explosions. See COAL, MINING.

Choking, in its slighter forms, is a very familiar occurrence, and results from a morsel of food or other solid, or even a drop of liquid, passing into the Larynx (q.v.) or upper opening of the windpipe, instead of the gullet, or in popular parlance 'going down the wrong way.' It is generally caused by a breath being suddenly drawn in coughing, laughing, &c. while food or fluid is in the mouth; and a violent fit of coughing follows till the offending substance is expelled from the windpipe. Sometimes, however, a larger mass—e.g. a half-chewed piece of meat—is drawn into the opening of the windpipe, completely blocking it, and arresting respiration altogether. This condition is one of extreme danger; the sufferer becomes purple in the face, and if not at once relieved will certainly and quickly die of suffocation. The obstructing substance is usually within reach, and may often be dislodged if a bystander promptly pushes his forefinger to the back of the throat and attempts to draw it forward. A child may sometimes be saved by holding it up by the heels and shaking it, or slapping its back. If these measures fail, a sharp-pointed knife, a penknife for instance, must be promptly pushed into the windpipe to admit air to it below the obstruction. See TRACHEOTOMY, ŒSOPHAGUS, PHARYNX.

In *cattle*, the causes fall under two heads: (1) those that depend on the material swallowed; and (2) those that depend on the animal swallowing. Under the first head we find sharp-pointed objects which become fixed into or entangled in the membrane lining the throat and gullet; solid masses too large to pass on to the stomach; dry farinaceous materials which clog in the passage. The second class of causes consists in inflammation of the throat, or irritation of the organs of deglutition; constrictions of the passage; ulceration of the Œsophagus, which is apt to follow choking, and is the cause of a relapse; lastly, without any disease of the deglutitory organs, an animal may be choked by eating too greedily, and imperfectly masticating or salivating its food.

The symptoms vary according to the position of the obstruction. Many of the most alarming symptoms arise from the paunch becoming distended by gas. See HŒVEN.

Remove the obstruction with the hand when you can. Cause the animal to swallow the substance, if possible, by giving it water, oil, or Belladonna solution. Carefully push the offending agent down by a probang, if it is possible to effect this, and if withdrawal by the mouth is impracticable. In some cases the gullet has to be cut into by a qualified surgeon. After a case of choking, keep the animal on soft food, and attend to its general health, in order to avoid a relapse, which is of frequent occurrence in cattle. Cattle are most frequently choked by sliced turnips and potatoes, and these should consequently be pulped or mashed.

Cholecystotomy, the opening of the gall-bladder. See CALCULUS.

Cholera (Fr. *choléra asiatique*). The Greek word *cholera* (connected with *cholē*, 'bile,' as is also the English 'choler') was used by both Hippocrates and Celsus to describe sporadic cholera (see below). The term is now rather loosely employed to denote various forms of disease (such as chicken cholera, for which see POULTRY). In this article it is used as the designation for Asiatic, Oriental, or Epidemic Cholera, otherwise called Cholera Morbus or Pestilential Cholera. This disease has been popularly believed to be a new disease which made its first appearance in Bundelkhand in 1817, when 5000 men died in five days; but there is no doubt that it has a far more ancient origin, and has visited Europe since 1500 A.D. Cholera is a specific disease characterised by violent vomiting and purging, with rice-water evacuations, cramps, and collapse; tending to run a rapidly fatal course, and capable of being communicated from person to person by means of the dejecta of patients suffering from it. The mortality of cholera varies in different epidemics; it is always greatest at the commencement of a fresh outbreak; at the lowest estimate one-half of the persons attacked die. Cholera has been endemic for centuries in certain parts of India, especially in the valley of the Ganges, and in the 19th century it has spread on various occasions almost all over the civilised world. In 1817-23 cholera spread rapidly throughout Bengal and other parts of India, Ceylon, Burma, and China, slaying thousands of victims. A second outbreak occurred from 1826-37, and spread *via* Central Asia and Russia with frightful virulence throughout Europe and America. From Riga it was imported to Sunderland (26th October 1831); from Hamburg to London (13th February 1832); and so it passed on to Paris, Quebec, Chicago, New Orleans, &c. In 1846-63 a third epidemic occurred, and Europe and America were again visited; 53,293 persons dying in England and Wales in 1848-49, and 20,097 in 1854. A very extensive outbreak took place in 1865-75; and in 1884-85 cholera reached France (especially Toulon and Marseilles), Italy (especially Naples), and Spain, but did not spread farther. The outbursts of cholera are generally sudden in their advent, hundreds of people being attacked within a few days of its appearance in any locality. It is a noteworthy fact that in each outbreak of cholera, one or other of its various symptoms is especially well marked.

Certain factors determine the origin and promote the diffusion of cholera. Places having a high altitude are prone to escape its ravages (at any rate for a long time), whereas low-lying ground favours its spread. During the general diffusion of cholera in India in 1817-19, the hill-forts remained exempt in a remarkable way, while the disease was prevalent in the plains around. There is no doubt too that cholera follows the rivers; and the more copious the saturation of the ground, and the greater the amount of organic matter undergoing decomposition it contains, the more extensive will be its spread. The drying of the soil after it has been soaked is very favourable for the development of cholera epidemics; and they are also favoured by certain physical characteristics of the soil, such as permeability to water and air, also by rocks that have a capacity for retaining moisture, and by organic detritus. But these are not the only factors we have to take into account, for climatic influences, such as heat and moisture, also affect its epidemic spread. Heat aids its production; a marked fall in the temperature and heavy rain stay its ravages, but rain after a prolonged drought often gives it impetus.

As to the exact nature of the morbid poison which causes cholera, authorities still differ, yet

in all probability a germ found in 1883 by Koch in the dejecta of cholera patients in Egypt, Calcutta, and Toulon, and named by him the 'Comma' bacillus, constitutes the morbid agent. His observations were to some extent confirmed by the researches of Klein and Gibbs in Calcutta and Bombay, and numbers of observers, notably Dr Macleod and Mr Miller at Shanghai in 1885, have since found the bacillus in the stools of cholera patients (see BACTERIA, GERM THEORY). The importance of this discovery can be estimated by the following fact. An Italian emigrant steamer arrived at New York in 1887, having on board a case of diarrhoea, the symptoms of which were suspicious but not perfectly typical of Asiatic cholera. Cultivation experiments were made at the Carnegie Laboratory of material discharged by this patient, and in four days they manifested the characteristic appearances due to the growth of the 'Comma' bacillus; and the diagnosis was subsequently confirmed by the occurrence of cases amongst the ship's passengers, in which the unmistakable symptoms of Asiatic cholera were present. It must, however, be said that bacilli similar to these do occur in healthy persons; they do not, however, give rise to the same appearance when cultivated by Koch's method as do the bacilli found in cholera stools. Further research is necessary to show in what way these bacilli cause cholera. The dejecta of cholera patients when perfectly fresh are innocuous, but very soon they develop the morbid agent, and water, food, or clothing contaminated by them will communicate the disease to healthy persons. Numerous observations go to prove that the wind also is capable of conveying the poison from dried cholera stools, but how far it is impossible to say. Troops or pilgrims may carry the infection and propagate it along their line of march; if healthy bodies of men meet with infected troops or enter a tainted district, they will almost certainly suffer; or if a body of men encamp on a site recently occupied by cholera patients, they will become affected. If cholera breaks out on board ship in mid-ocean, it will be coincident with the exposure of some part of the cargo from an affected place.

Causes.—(a) *Predisposing*.—Fear or shock, exposure to sudden changes of temperature, intemperance in labour, pleasure, or drink, and want of proper clothing, as well as everything which tends to derange the stomach, or the use of strong purgatives, predispose a person to an attack of cholera; and fresh arrival into an infected area renders a person extremely liable to an attack. (b) *Exciting*.—This is of course the entrance into the body of the poison, which may be introduced into the system either by drinking-water, or by food contaminated with the discharge of a cholera patient. It may also be inhaled as dust, and enter the body through the lungs. There can be no doubt that polluted drinking-water is by far the most common source of infection; and it has been noticed, as for instance in Calcutta, that the improvement in the water-supply has greatly diminished the prevalence of cholera.

Symptoms.—After some premonitory symptoms characterised by malaise, depression, and slight diarrhoea, cholera commences by purging, to be soon followed by vomiting and painful cramps in the stomach and limbs. These symptoms form the first or evacuation stage. The discharges downwards are extremely copious, and they soon become colourless and turbid, resembling water in which rice has been boiled; hence the expression, 'rice-water' evacuations. In the second stage, which is called the 'algid' stage, there is profound collapse. In this condition the patient lies motionless and

apathetic, except when tormented by cramps, which are of frequent occurrence. The surface temperature of the body falls to 95° F., or even lower. The pulse becomes almost imperceptible, and the respirations are shallow and rapid, the air expired being cold, and the voice a hollow, husky whisper. The nervous system suffers severely, and muscular prostration is well marked. The features assume a leaden or livid hue; they are pinched and shrunken. The nose becomes sharp and pointed, the cheeks hollow, and the eyeballs, which are often bloodshot, sink in their sockets and are nearly hidden by the half-closed lids. The surface of the body, especially the extremities, is bluish, wrinkled and shrivelled, and bathed in cold clammy sweat. For a time the mind is clear but inactive; in fatal cases, however, stupor sets in, followed by coma; thirst is intense. In this stage assimilation and secretion are in abeyance; all the vital processes in fact are brought almost to a standstill. This stage may last from twelve to thirty-six hours, when the third stage, that of reaction, gradually commences. Heat returns to the surface of the body, the breathing becomes regular and calm, the secretions are re-established, the pulse improves, and the patient will fall into a calm sleep. This stage may terminate in speedy convalescence, but such is not always the case, as a relapse may take place and certain complications and sequelæ follow. The most dreaded of these are suppression of urine, uræmia, and fever, often closely resembling typhoid, and constituting, at least in the temperate zone, one of the chief dangers in the progress of cholera. Disease of the kidneys, inflammation of the lungs, ulceration of the cornea, abscesses all over the body, and hemorrhage from the bowels may also occur. The mortality varies very much: it may be from one in four of those attacked to three in four. In some epidemics in India it is not more than 15 per cent. of those attacked; in others as high as 90 per cent. In 1835 it was announced that of 233,516 persons attacked in Spain during the recent epidemic, 82,619 succumbed. One attack of cholera does not confer protection against another.

Treatment. With regard to treatment, medicines are almost powerless, and many of the vaunted remedies undoubtedly do far more harm than good. It is, however, necessary to try to check the premonitory diarrhœa, as by so doing in many cases the disease may be cut short. The slightest symptoms of diarrhœa should be attended to; the patient should be put to bed, a mustard plaster should be applied to his abdomen, and opium in some form or other should be administered. A favourite prescription is four grains of acetate of lead with one of opium, which may be given after each loose stool until three doses have been taken; or else thirty drops of laudanum in half a glass of brandy in hot water. In the state of collapse it is useless or even injurious to give medicine, but soda-water and ice may be administered to relieve thirst. During collapse the medicines could not be assimilated, and if given then, during reaction they would be absorbed and do harm. As soon as reaction occurs, thin water-arrowroot should be given in small quantities, and then iced milk, chicken-tea, and beef-tea, as the stomach can stand it, and enemata of beef-tea should be given every four hours.

The true remedy against cholera is undoubtedly prevention. The greatest care should be taken to secure pure drinking-water, which should be boiled before use, and uncontaminated food. Personal cleanliness, free ventilation, and thorough disinfection of the drains should be enjoined. With regard to quarantine, it is worse than useless in checking the spread of cholera; but all persons coming from an infected area who have the slightest tendency to

diarrhœa should be isolated and carefully watched. It should be remembered with what ease cholera can be conveyed by clothing, and therefore the importation of all rags and old clothes should be prohibited. Lastly, the destruction of the discharges from cholera patients, and of the linen soiled by them, is of the utmost importance. The dead should be buried immediately, being covered with a mixture of lime, charcoal, and carbolic acid. A Spanish physician, Dr Ferran, employed preventive inoculation as a safeguard against Asiatic cholera in 1885, but his methods were discredited; and Dr Gamaleia of Odessa rendered pigeons and guinea-pigs proof against the disease by inoculating them with prepared virus.

A very rare form of cholera—*Cholera Sicca*—is sometimes met with, in which the symptoms of collapse occur, with great coldness and blueness of the surface, and death takes place in a few hours, without any purging.

Cholera Nostras is also called Simple Cholera, Summer Cholera, British Cholera, Sporadic Cholera, Choleraic Diarrhœa. This is an acute catarrhal affection of the mucous membrane of the stomach and small intestines, which usually occurs in late summer or early autumn. It is attended by vomiting and purging of bile, cramps and pain in the bowels, the whole system being implicated on account of the rapid loss of water from the body. This disease, although severe, is usually only fatal to young infants or to old or debilitated persons. The treatment of simple cholera is that of Diarrhœa (q.v.). See Pettenkofer's *Cholera: How to Prevent and Resist it* (Eng. trans. 1884); Stillé's *Cholera: Origin, History, and Prevention* (Phila. 1885); and Bellew's *History of the Cholera in India* (1884).

Cholesterin, $C_{26}H_{44}O$, is a fatty substance, originally found in gall-stones, but now known to be present in the yolk of egg, the blood-corpuscles, milk, and other animal fluids, as well as in peas, barley, rye, &c. It is soluble in alcohol and ether, and separates from its solutions in glistening nacreous scales.

Cholet, a town of France, in the department of Maine-et-Loire, on the right bank of the Maine, 32 miles SW. of Angers by rail. It has manufactures of linen, woollen, and mixed fabrics. Pop. (1872) 11,550; (1886) 14,826.

Cholu'ta, a once flourishing, but now decayed, town of the Mexican state of Puebla, stands nearly 7000 feet above sea-level, on the tableland of Anahuac, 55 miles ESE. of the city of Mexico. Cortes found in it 20,000 houses, and as many more in the suburbs, and also 400 temples. Now the place contains only 9000 inhabitants. It was a great centre of the Aztec religion. Its most remarkable memorial of aboriginal times is the huge *Teocalli* pyramid of earth, clay, brick, and stone, dedicated to the god Quetzalcoatl. See **TEOCALLI**.

Chondrin. See **GELATIN**.

Chondropterygil. See **CARTILAGINOUS FISHES**.

Chonos Archipelago, a group of islands off the west coast of Patagonia, 44°–46° S. lat., belonging to Chili. They are almost all bare and scantily peopled.

Chopin (Fr.), an old English liquid measure equal to half a pint. The Scotch *chappin* was nearly an English quart. The German *schoppen* is a pint.

Chopin, FRÉDÉRIC, virtuoso and musical composer, was born March 1, 1809, at Zelazowa Wola, a village near Warsaw, in Poland, where his father, a native of Lorraine, had settled and married. Under the tuition of two professors at Warsaw, notably Elsner, the director of the Conservatoire,

Chopin made such rapid progress that at the age of nine he played with success in public. As a boy and, indeed, until his health broke down beneath the strain of Parisian life, he possessed a great fund of high spirits, and excelled in mimicry and caricature. In 1825 he published his first work, and by the time he was eighteen his parents acquiesced in his choice of music as a career. In the autumn of 1829 he visited Vienna, gave a successful public concert, and was in much request in the *salons* of that city. In the following year he left Warsaw for good, and travelling *via* Breslau, Dresden, and Prague, again visited Vienna, where he sojourned for several months, and he started for Paris in July 1831. Here, after sundry vicissitudes, he took root, found fame, and lost his health; here he became the idol of the *salons* of the Faubourg Saint Germain, giving lessons to a select *clientèle* of pupils, and employing his leisure in composition. Chopin rarely performed in public, for, as his biographer remarks, 'he could only play *con amore* when in the best society and among connoisseurs who knew how to appreciate all the niceties of his performance.' But in his element Chopin, by the admission of so competent a judge as Mendelssohn, was 'a truly perfect virtuoso' as well as a thorough musician, with a faculty for improvisation such as perhaps no other pianist ever possessed. In 1836 he was introduced to George Sand (Madame Dudevant) by his friend Liszt. The intimacy which thus began lasted for seven years, when George Sand, to quote Liszt, 'gave her butterfly the *congé*, vivisected and stuffed it, and added it to her collection of heroes for novels.' For George Sand's version of this episode, readers may be referred to the fourth volume of her *Histoire de ma Vie*, as well as to the portrait of Prince Carol in her novel *Lucrezia Floriani*. Chopin visited England on two occasions—once in 1837, and again in 1848. In the latter year he played at two *matinées* and at a Polish ball in London; twice in Manchester, once in Edinburgh, and once in Glasgow. His health, long enfeebled by consumption, gave way rapidly on his return to Paris, where on the 17th of October 1849 he passed away tranquilly, surrounded by a few devoted friends.

Of all *virtuosi* Chopin has achieved the greatest fame as a creative artist. Taking Slavonic airs and rhythms, notably that of the Mazur or Mazurek (Mazurka), for his groundwork, he raised upon this basis superstructures of the most fantastic and original beauty. His style is so strongly marked as to amount to a mannerism, and yet he has only been successfully imitated by men of genius like Schumann, who was amongst the first of the German critics to recognise in his early compositions gifts of the rarest order. Chopin had seldom recourse to the orchestra to express himself, and on these rare occasions treated it in perfunctory fashion, and as a mere foil to the solo instrument. But for the piano alone he wrote a great deal of music superlatively artistic in form, impregnated with subtle romance, and full of exuberant fancy—music which, though it must always primarily appeal to refined and fastidious natures like his own, bears on it the unmistakable stamp of spontaneous inspiration. Personally Chopin was of a reserved but amiable nature, singularly modest as to his merits, but unsparing in his efforts to realise the high and clearly defined aims he had set before him. His compositions, the best edition of which is that published by Carl Klindworth of Moscow, extend to 74 works with, and 7 without *opus* numbers; and comprise upwards of 50 mazurkas, 27 *études*, 25 *préludes*, 19 nocturnes, 13 waltzes, 12 polonaises, 4 ballades, 4 *impromptus*, 3 sonatas, 2 concertos for piano and orchestra, and a funeral march. Besides rendering his friend the doubtful

service mentioned above, Liszt is also responsible for having given currency in his picturesque apotheosis of Chopin to a good many inaccurate statements as to his education and temperament. These have been corrected and several debatable points cleared up in the *Life* published by Moritz Karasowski (Dresden, 1877; Eng. trans. 1879).

Chopine (Span. *chapin*), a 'high clog or patten,' introduced into England from Venice during the reign of Elizabeth. Some chopines were as much as half a yard high; they are mentioned by Shakespeare in *Hamlet*.

Choragus. See CHORUS; and for the Choragic monuments, see ATHENS, Vol. I. p. 539.

Chorale. Though the name is occasionally applied to the psalm and hymn tunes of similar character used in the Protestant churches of France and Britain, it most properly belongs to the melodies sung to the metrical hymns of the German Reformed Church, and introduced by Luther, by whom and his friend Walther the first collection of importance was produced in 1524, and entitled the *Einigkeit*. The settings were in four, five, or six parts, the melody, as with all the old chorale hymns and psalms, being given to the tenor. Numerous other collections appeared down to the latter part of the 17th century, the most prolific composer of chorales being Johann Crüger. Many of them were harmonised in the most masterly way by Bach, and were also used by him as the *canto fermo*, or subject, of some of his great contrapuntal works. Some of them were adapted from the old hymn tunes of the Roman Church, others were taken from popular airs of the time, others again were original compositions; among the latter the most notable is Luther's 'Ein feste Burg.' Whatever their source, they all possess in common a solemn, dignified, and devotional character. In Germany they are now usually sung very slowly and heavily in unison, with organ accompaniment. A few of them are well known in this country from their introduction in various collections of hymn tunes, and also in the choral works of Bach and Mendelssohn.

Choral Service, the musical service of the Church of England, celebrated by a full complement of clergymen, lay clerks, and choristers, when all those parts of the service are sung or intoned as ordered in the rubrics. See CHOIRS.

Chord. The chord of an arc is a straight line joining its two extremities; or, a chord, in a circle, ellipse, parabola, &c. is a straight line joining any two points in the curve. If we draw a series of parallel chords in any conic, the line through their middle points is called a diameter, and a line parallel to the chords which passes through the extremity of the diameter is a tangent to the curve. Hence in the circle (1) a diameter is perpendicular to the chords which it bisects, and also (2) to the tangent at its extremity; (3) the three chords of intersection of any three circles meet in a point. In any conic the tangents at the ends of any chord meet in the diameter which bisects the chord. A SCALE OF CHORDS on Mathematical Instruments is sometimes used for setting off angles, but has been mostly superseded by the Protractor (q.v.).

Chord, in Music, is the simultaneous and harmonious union of sounds of different pitch. The common chord is a note with its third and fifth

reckoned upwards, thus: ; or in the tonic sol-fa notation, *m*: this is the basis of all Harmony (q.v.). The subject of chords will be discussed under MUSIC.

Chorea (Gr. *choreia*, 'a dancing' or 'jumping'), a disease popularly called *St Vitus's Dance*, and consisting of a tendency to involuntary and irregular muscular contractions of the limbs and face, the mind and the functions of the brain generally being quite unaffected. The spasms of chorea differ from those of most other convulsive affections in being unaccompanied either by pain or by rigidity; being, in fact, momentary jerking movements, indicating rather a want of control of the will over the muscles than any real excess of their contractions. In some cases the disease resembles merely an exaggeration of the restlessness and 'fidgetiness' common among children; in others it goes so far as to be a very serious malady, and may even threaten life. Fatal cases, however, are fortunately very rare, and in the large majority of instances the disease yields readily to treatment carefully pursued, or disappears spontaneously in a few weeks or months. Chorea is a disease much more common among children of six years old and upwards than at any other period of life; it is also more common among female children than among males. Not infrequently it follows a fright or other mental shock, or the strain of overwork. In a large proportion of cases it is associated with acute rheumatism (rheumatic fever), or with heart-disease (endocarditis). The treatment generally pursued is the use of metallic tonics, such as zinc, copper, iron, and arsenic (the last, perhaps, the best), sometimes preceded or accompanied by purgatives. Anti-rheumatic remedies are in some cases very valuable. Exercise in the open air is also to be recommended; and gymnastics afford material aid in the cure. It is to be observed that the name *St Vitus's Dance* (see *VITUS*) was applied originally in Germany to a different form of disease from that above referred to—one closely approaching in its characters the epidemic 'dancing mania,' which, in Italy, was called *Tarantism* (q.v.).

Chorion. See *PLACENTA*.

Chorley, a busy town in North Lancashire, 9 miles SE. of Preston by rail. It has thriving manufactures of cotton-yarn, jaconets, muslins, fancy goods, calicoes, and gingham. Railway wagons are also built, and in the vicinity are bleach-fields, print-works, coal-mines, and stone quarries. Pop. (1881) 19,472.

Chorley, HENRY FOTHERGILL, musical critic, was born at Blackley Hurst, in Lancashire, 15th December 1808, and was educated in Liverpool. He became a member of the staff of the *Athenæum* in 1833, and soon had entire charge of the musical department, from which he retired in 1868; he contributed also very many literary reviews. He published some half-dozen artificial and unsuccessful romances, three acted dramas, and some graceful verse; but it is by his *Music and Manners in France and Germany* (1841) and his charming *Thirty Years' Musical Recollections* (1862) that his name is best known to the reading public. He held very decided opinions in music (hostile to Berlioz and Wagner), and expressed them uncompromisingly; and his insight was perhaps discriminating rather than profound. He died 16th February 1872. See the *Autobiography, Memoir, and Letters*, edited by H. G. Hewlett (1873).

Choroid. See *EYE*.

Chorus, among the ancients, meant a band of singers and dancers employed on festive occasions of great pomp, and also in the performance of tragedy and comedy on the stage. The choral dances in honour of Bacchus, which superseded the earlier ones to Apollo, were by their combination with the rhythmic recitations of the Rhapsodes, the origin of the Greek tragedy. In the plays as

known to us the chorus consisted of a group of persons—boys, girls, or men—who remained in front of the stage during the whole performance as spectators, or rather as witnesses. When a pause took place in the acting, the chorus either sang or spoke verses having reference to the subject represented, which served to increase the impression or sensation produced by the performers. At times the chorus seemed to take part with or against the persons in the drama, by advice, comfort, exhortation, or dissuasion. In the comedy the chorus also addressed the audience. In the time of *Æschylus* the chorus was very large, sometimes consisting of upwards of fifty persons, but the chorus of *Sophocles* numbered only fifteen. Its leader was termed the *Coryphæus*. The charge of organising it was considered a great honour among the citizens of Athens. The person appointed for this purpose was called the *choragus*. The honour was very expensive, as the choragus had to pay all the expenses incurred in training the members of the chorus to perform their parts efficiently. They were, besides, fed and lodged by him during training-time, and he had also to provide for them masks and dresses. At times the chorus was divided, and spoke or sang antiphonally. These divisions moved from side to side of the stage, from which movement originated the naming of the single songs or stanzas, such as *Strophe*, *Antistrophe*, and *Epode*. How the musical element of the ancient chorus was constituted or composed is not known with any certainty. It was pre-eminently founded on rhythm, the employment of which was very varied; and it was doubtless very simple. It was accompanied by flutes. With the decline of the ancient tragedy, the chorus also fell into disuse; and only lately has there been an attempt to produce the same on the stage in the manner of the ancients, as, for example, in Schiller's *Bride of Messina*. The music which has been set in modern times to some of the Greek tragedies does not give the least idea of the original music, which to our ears would probably sound very bare and rude. Three fragments of a Greek hymn of a late Roman period (from a Neapolitan manuscript, and the Florentine work of Galilei), which are the only extant remains of Greek music, have been transcribed in modern notation in Rowbotham's *History of Music*, vol. ii., and also in Chappell's *History of Music*, vol. i. They are of interest as being connected with the origin of the modern opera. In his later operas Wagner professes to assign to the orchestra the functions of the Greek chorus.

In modern music the word is applied to vocal pieces in which each part is intended to be sung by a considerable number of voices; and also to the body of singers who perform choral music. The number of parts may vary from unison to as many as forty or fifty; the normal number is four, but five and eight parts are also frequent. When the voices are divided into two choirs, it is called a *double chorus*. A chorus for both male and female voices is termed a *mixed chorus*. The forms of chorus are more varied than those of solo music, and the most characteristic are imitative, or contrapuntal, of which the fugue is the most regular type. They may also be in simple harmony, or a combination of the two. Choral recitative is sometimes introduced; a solo voice, or even a solo instrument, may be accompanied by chorus, or solo and chorus may answer antiphonally. A chorus sung without accompaniment is called a *capella*. The earliest extant form is the unisonal *Plainsong* (q.v.) of the Roman Church. In oratorio music, Bach's great *Passion Music* may be cited as containing nearly every form of chorus, from those constructed with figured parts upon a *canto fermo*,

to the dramatic *turba*, the shouts of the enraged people. The double choruses in Handel's *Israel in Egypt* are also celebrated for their masterly construction and grand massive effect; and for dramatic expression those of Mendelssohn's *Elijah* stand in the highest rank.

In the opera as originally conceived by Peri and Caccini at the close of the 16th century, the chorus was intended to imitate that of the Greek play; and down to the time of Gluck it was arranged in two rows, without taking part in the action of the piece. Since his reforms the members of the chorus are also *dramatis personæ*, and sometimes, as in Auber's *Masaniello*, play a most important part. A definite rhythm seems essential as a means of keeping the parts together in a chorus of any length; even when Wagner, who considered rhythm 'an intruder in music,' introduces choruses, which he does but sparingly, in his operas, they are at once noticeable for this feature.

Choral singing has within the last forty years obtained a widely popular development in Britain and America, greatly owing to the publication of cheap editions of classical music. The chorus singers of Yorkshire are recognised as excelling; but it need scarcely be said that in this department of singing a very great deal of the effect depends on the conductor. A remarkable feature of the Crystal Palace Handel festivals is the gigantic body of chorus, amounting in 1888 to over 3000. See CHOIRS.

Chose in Action (Fr. *chose*, 'a thing') is one of the two great classes of what the English law calls chattels personal. The one class is 'choses in possession,' such as goods, household furniture, cattle, &c.; the other class is 'choses in action,' such as the right to sue for a debt, a legacy, damages, &c. The old common-law rule was that, except in the case of negotiable instruments, contracts could not be assigned so that the assignee might sue in his own name; but the assignee must bring his action in the name of the assignor or cedent, so that the assignee was always exposed to every defence which might have been stated against the original debtor under the contract. This resulted from the primitive view of contract as creating a strictly personal relation between the debtor and creditor. The Equity Courts, however, permitted the assignment of debts and equitable rights, notice being given to the debtor to preserve priority; and in particular cases—e.g. policies of insurance under a statute of 1867, the full right of assignment was permitted. Now, under the Judicature Act, 1873, every legal chose in action is absolutely assignable if express notice in writing be given to the debtor; and although the words of the statute do not extend to assignment by way of security, or to any assignment of what is called an equitable chose in action, there is now little practical distinction between the two.

In the United States that quality of a chose in action rendering it unassignable at common law is fast disappearing. In some states a chose in action may not only be assigned, but the assignee may bring a suit for possession in his own name; while in others the name of the assignor is used as plaintiff in the action, to the use of the assignee. Courts of law generally follow the rules of equity in this respect.

Chosŏn. See COREA.

Chosroes is the Byzantine spelling of the Persian KHOSRŪ or KHŪSRŪ. Chosroes I. (531–579 A.D.) was the greatest monarch of the Sassanian dynasty, and was called Anōsharvān, 'the blessed.' He carried on war with the Roman emperor for twenty years, and at home promoted agriculture,

commerce, and science. Chosroes II., his grandson (590–628), during fifteen years inflicted on the Byzantine empire disasters such as they had never experienced; Syria, Palestine, Egypt, and even Chalcedon being conquered. See PERSIA.

Chota Nagpore (*Chutid Nagpur*), a south-west division or commissionership of Bengal, embracing four British districts, seven petty tributary states, and two semi-independent states, with a surface for the most part wild and hilly. Area of the British districts, 26,966 sq. m.; pop. (1881) 4,225,989. Area of the division, 43,020 sq. m.; pop. (1881) 4,903,991, of whom 768,806 belonged to aboriginal tribes.

Chouans, the name applied to the royalist insurgents who, during the French Revolution, organised a reactionary movement in Brittany. The name may very probably be due to a corruption of *chat-huant* ('screech-owl'), from the nocturnal habits of the bands or from some special call of recognition they may have had; or it may have originated in a nickname of the instigator of this insurrection, one Jean Cottereau, a smuggler of noted sagacity and courage. In the year 1792 they began to wage a small guerilla warfare with some success, but the *Chouannerie*, as the insurrection was called, at first disgraced itself by drunken license and cruelty. After Cottereau's death in 1794 in a scuffle near the wood of Mison, the theatre of his first efforts, the brave adventurer Désoteux, surnamed Cormatin, took the lead; but after his capture there arose new leaders who extended the insurrection and lifted its aims into the region of the heroic. Georges Cadoudal and Charette soon had under their command a force of 10,000 fearless men, and their energy and daring actually imperilled for a time the security of the republican government in France. But stubborn and strong as was the old unquestioning loyalty of Brittany, it could not withstand the fiery enthusiasm that impelled the conquering legions of the giant young republic across almost the whole continent of Europe. The insurrection was stamped out by La Hôche; its leaders Viennville and Sérent fell, Scépeaux and Cadoudal were forced to lay down their arms, Frotté fled to England and Puisaye to America. A new attempt in 1799 was soon mercilessly crushed, and henceforward Chouannerie could only smoulder on in secrecy. In 1814–15 it again made its appearance on both banks of the Loire; and after the July revolution (1830) was once more excited by the Duchess of Berri on behalf of the Duke of Bordeaux, but crushed by the energetic measures taken by Thiers.

Chough (*Fregilus*), a genus of birds of the crow family (Corvidæ). The beak is longer than the head, strong, arched, and pointed. The tail is slightly rounded. The common European species, sometimes called the Cornish Chough, or Red-legged Crow (*F. graculus*), is a widely distributed but very local bird, inhabiting the Alps and other mountainous parts of the palaearctic region. In Cornish folklore King Arthur did not die, but was changed into a chough, and it is interesting to find this English belief alluded to in *Don Quixote* (ii. 5), though here the bird is erroneously made a raven. Shakespeare in *King Lear* (IV. vi.) confounds the chough with the jackdaw; and in *Midsummer-Night's Dream* (III. ii.) actually speaks of 'russet-pated choughs.' The chough occurs on some parts of the British sea-coasts, but almost exclusively confined to situations where there are high cliffs. Its long hooked claws enable it to cling easily to a rough rock, but it seems unwilling even to set its feet on turf. It lives in societies like the rook, and feeds on insects, berries, grubs, and grain. It is easily tamed, becomes very

familiar and forward, and exhibits in the highest degree the curiosity, the pilfering disposition, and the delight in brilliant or glittering objects which also characterise others of the crow family. The

Chough.

name is sometimes extended to allied forms, such as *Pyrrhocorax alpinus* (Alpine Chough).

Choya. See CHAY ROOT.

Chrestomathy (Gr. *chrēstos*, 'useful'; *mathein*, 'to know') is a name for books of selections from foreign languages, usually provided with glossary and notes for the use of learners. See ANTHOLOGY.

Chrétien de Troyes, an old French poet of whose life nothing more is known than that he lived in the second half of the 12th century and was a favourite poet at the court of Mary, daughter of Louis VII. and wife in succession to the Counts of Champagne and of Flanders. He worked up the legends of the Round Table into numerous spirited and yet refined poems in octosyllabic verse, which had a wide literary influence, and were translated by the German minnesingers, Wolfram von Eschenbach, Gottfried of Strasburg, and others. The most important of these poems was *Perceval le Gallois*, or *Li Contes del Graal* (containing 50,000 verses); *Li Romans dou Chevalier au Lyon*; *Li Contes d'Erec*; and *Lancelot du Lac*, or *Le Chevalier de la Charrète*. A complete collection of his works was begun by Wend. Förster (vol. i. Halle, 1884). See Paulin Paris, *Les Romans de la Table-Ronde* (5 vols. 1868-77).

Chrism (Gr. *chrisma*, 'ointment') is the name given to the oil consecrated on Holy Thursday, in the Roman Catholic and Greek Churches, by the bishop, and used in baptism, confirmation, ordination, and extreme unction. There are two kinds of chrism—the one, a mixture of oil and balsam, is used in baptism, confirmation, and orders; the other, which is merely plain oil, is used in extreme unction.

Chrisome, the name of the white linen cloth laid by the priest on the child in Roman Catholic baptism, to signify its innocence. By olden usage it was generally presented by the mother as an offering to the church, but if the child died before the mother was 'churched' again, it was used as a shroud. By a common abuse of words, chrisome came to mean the child itself, being first applied in the old bills of mortality to denote such children as died within the month of birth. Mrs. Quickly's use of the phrase in her account of Falstaff's end will be remembered. The following from Jeremy Taylor (*Holy Dying*, i. 2) explains itself: 'Every morning

creeps out of a dark cloud, leaving behind it an ignorance and silence deep as midnight, and undiscerned as are the phantasms that make a chrisome child to smile.'

Christ (Gr. *Christos*) is the word used in the New Testament and in the Septuagint as the equivalent of the Hebrew word *Messiah* (q.v.). Both words mean 'anointed.' When kings and priests, and sometimes prophets; were set apart for the discharge of their respective functions, it was customary to anoint them with oil in the name of the Lord (1 Sam. x. 1, xii. 3; Exod. xxix. 7, xxx. 23-33; 1 Kings xix. 16); hence the term. Oil was used in the ceremony because it was regarded as emblematical of the Holy Spirit and of salvation (1 Sam. xvi. 13, x. 1, 9, 10; Isa. xi. 1, 2, lxi. 1-3; Acts x. 38).

In a secondary sense the word is applied to persons set apart by God for some special end, though they were not literally anointed. Thus Cyrus, the king of Persia, is spoken of as the Lord's anointed (Isa. xlv. 1), because he was Jehovah's chosen instrument for setting free the captives in Babylon. We find it used, in the plural, regarding the patriarchs Abraham, Isaac, and Jacob (Ps. cv. 15). It is also applied to the chosen people as a whole (Hab. iii. 13, revised version).

As applied to Jesus, the word is used in a two-fold sense—as an appellative, and as a proper name. At first it was used in the former sense with the article—'the Christ'—but at a later period—e.g. in the epistles of Paul, and in 1 Peter, it is found to have passed over into a proper name. When used as a title of office it manifestly looks back to the Old Testament doctrine of the Messiah. That doctrine may be briefly indicated by a reference to three passages. We find the Messiah represented as the messenger of good tidings to men = God's *Prophet*—in Isa. lxi. 1; as making expiation for sin = God's consecrated *Priest*—in Daniel, ix. 24-27; and as the *King* of God's heritage in Ps. ii. 2. When Jesus, therefore, claimed to be the Messiah (cf. John, iv. 26), he undoubtedly meant it to be understood that the Old Testament ideals connected with the title were realised in him. In his person, that is to say, the offices of prophet, priest, and king were united and consummated. That it was thus that his disciples understood his claims is patent to every reader of the New Testament. So thoroughly filled were they with the Messianic idea of his mission that, as we have seen, the official title, 'the Christ,' came to be largely used by them, without the article, as his proper name.

When Jesus came thus to be spoken of as Christ, or Jesus Christ, it was but natural that his followers should be called after him, Christians. This name, Tertullian informs us (*Apol.* c. 3), was often mispronounced *Chrestiani* by those who were not conversant with Jewish ideas. They manifestly thought that it was derived from the Greek *Chrestos* = good. The Christians, we are told, instead of taking umbrage at this distortion of their current name, gladly accepted it as implying an admission on the part of the heathen of the moral excellency both of their Master and of themselves. For the Life of Christ, see JESUS.

CHRISTOLOGY is that branch of theology which treats of the Person of Christ. No attempt was made in apostolic times to formulate a Christology; the early church contenting itself with testifying to the true, yet sinless humanity, the pre-existence, the divine Sonship, the resurrection, the exaltation, and the supreme authority of its Founder. It was not till speculative minds began to broach ideas inconsistent with this accepted faith that a theological representation of the church's views was found necessary. The symbolic form in which the generally accepted doctrine

has been handed down to us was the result of prolonged, and not unfrequently acrimonious discussions. Prior to the Council of Nice (325 A.D.) various Christological theories were promulgated by the Ebionites, to whom belonged the Nazarenes, the Cerinthians, and the Gnostics of the pseudo-Clementine type, by the Docetae, and by the Gnostics proper. Some of these denied the pre-existence of Christ, and attributed his peculiar greatness to a supernatural endowment conferred upon him at his baptism, while others resolved his humanity into a mere phantom, and represented his person as composed of a spiritual *Åon*. These parties were, however, but short-lived. More formidable were the Sabellians and the Arians. The former denied the doctrine of the immanent Trinity. To them, accordingly, the higher nature of Christ was simply absolute Deity in self-manifestation. The Arians, on the other hand, represented Jesus as the first and loftiest of God's creatures. In their view he was not, therefore, truly God. It was specially with a reference to these two opposing parties that the Council of Nice was summoned by Constantine. The results of the deliberations of this council are embodied in the well-known Nicene Creed. Both Sabellianism and Arianism were pronounced heretical, and the eternal Sonship of Christ was solemnly asserted. The question, however, remained undecided how the union between the divine and the human in his person was to be expressed. Apollinaris, Bishop of Laodicea, advanced the theory that Christ's manhood was constituted solely of an animal soul and body, while the *Logos* took the place of the mind, or spirit, in him. His true humanity was thus denied. Nestorius, Bishop of Constantinople, started a rival theory. While granting the true divinity and humanity of Christ, he denied their union in a single, self-conscious personality. According to him the union was only moral or sympathetic. The Nestorian theory thus involved the breaking up of the personality into a duality. Eutychus of Constantinople wrote against Nestorianism, but his zeal carried him to the other extreme. His contention was that in the incarnation the human was transmutated into the divine. He thus obliterated the humanity.

At the Council of Chalcedon (451 A.D.) all these views were condemned, and the Christological formula which is still regarded as orthodox was framed. The orthodox doctrine, briefly stated, holds that in the unity of the person of Jesus Christ there are two natures, a divine and a human, each nature being complete and entire, and that these are so intimately and indissolubly united as to constitute not a third nature, but a person. It warns us against either dividing the person or confounding the natures.

Notwithstanding the adoption of this creed, controversy was not by any means brought to an end. For more than three centuries questions of extreme subtlety continued to agitate the theological world—questions pertaining to the relation of *nature* to *personality*, and of both to *will*. The Monophysite, the Monothelite, and the Adoptionist controversies were concerned with these abstruse points. At the Council of Constantinople (681 A.D.) it was decided that in the one person of Christ there are two natures, two intelligences, two energies, and two wills. The condemned Monothelites were consequently persecuted, and they betook themselves to the mountains of Lebanon and Anti-Lebanon, where they continued to exist as a distinct sect under the name of Maronites. During the middle ages the church as a whole acquiesced in the decisions of the above-named councils, though individuals occasionally ventured to give expression to views more or less at variance with the

creeds. In our day, Dyothelitism, or the doctrine that there are two wills in Christ, is not regarded as essential to orthodoxy. In fact it is largely denied among theologians of high repute.

At the time of the Reformation Christology once more became a subject of keen controversy. The occasion was a difference of opinion between Luther and Zwingli regarding the presence of Christ in the elements of the ordinance of the Supper. Eventually the Lutherans accepted the doctrine of the *communicatio idiomatum*—i.e. the communication of the properties of the divine nature of Christ to his humanity. By this doctrine they sought to establish the ubiquity of Christ's body. The Lutheran dogma was rejected by the Reformed theologians.

The next important movement in connection with Christology originated with Lælius Socinus (1525-62) and his nephew, Faustus Socinus (1539-1604). They taught that Christ was a mere man, but distinguished from all others in the following particulars: He was miraculously conceived, was sinless, was specially endowed with the Holy Spirit, was taken up to heaven prior to the commencement of his ministry, in order that he might see God and receive instructions from him, he rose from the dead and is now exalted in heaven far above all creatures, he is invested as God's viceroy with all power in heaven and in earth. In view of his exaltation they taught that Christ may justly be termed a God, in a sense different from that in which rulers are termed gods, and therefore he ought to be worshipped. Unitarians, who may be regarded as the modern representatives of the Socinians, speak of Christ as the Ideal Man, but probably none of them would accord him all the high distinctions above specified.

At the present day there is in vogue a Christological theory known as the doctrine of *kenōsis* (*kenos*, 'empty'), which is variously set forth by a considerable number of evangelical theologians. It derives its name from the Greek verb *ekenōse* which occurs in Philip. ii. 7. In its modern form the theory is probably traceable to Zinzendorf. It is advocated by such writers as Thomasius, Gess, and Godet. Its aim is to do justice to the genuine development of the Man Jesus Christ. This it seeks to accomplish by postulating an *emptying* of himself on the part of the *Logos* in the act of incarnation. He laid aside, it is said, not only his divine attributes, but even his divine self-consciousness. These he gradually regained during the course of his earthly history, and by the time that he ascended the process was complete. Such in brief is the theory. What its future may be it is vain to guess. As yet, however, the great mass of orthodox theologians look askance at it.

According to Shedd, the following four factors are necessary in order to a complete conception of Christ's Person: (1) True and proper deity; (2) true and proper humanity; (3) the union of deity and humanity in one person; (4) the distinction of deity from humanity in the one person, so that there be no mixture of natures.

The standard book on the history of Christology is Dörner's *Doctrine of the Person of Christ*. See also Bull's *Defence of the Nicene Creed*, and his *Judgment of the Catholic Church*, &c.; Bruce's *Humiliation of Christ*; Hagenbach's *History of Doctrines*; and the separate articles on the heresies (ARIUS, NESTORIUS, &c.).

Christadelphians, a religious body which adopted this name during the American civil war to avoid military service. The Christadelphians (or 'Brethren of Christ') claim to represent the true faith and practice of apostolic times, as revived by Dr John Thomas, Brooklyn, U.S., who was born in 1805 and died in 1871, and was the leading advocate of their views. (After him they are

sometimes called Thomasites.) They deny the existence of a personal devil, and the immortality of the soul, believing in 'Conditional Immortality' (q.v.), to be bestowed upon the faithful of all ages when Christ returns. They insist on the plenary inspiration of the Bible, the real death of Christ as a sacrifice for sin, his resurrection and ascension; and look for his return to the earth to reign on the throne of David over the converted and restored twelve tribes of Israel and all nations. They believe that death is a state of entire unconsciousness, terminated by a corporeal resurrection for those who have become related to Christ through faith and obedience, or are responsible for his rejection. Those accepted after the judgment reign for ever with Christ over the nations, those rejected die the second death. Communities of Christadelphians exist in the principal towns of Great Britain, Ireland, the United States, and the colonies, but no statistics as to numbers exist. Probably the members amount to a few thousands. Their leading organ is *The Christadelphian*, published monthly in Birmingham, and founded by Robert Roberts, whose work, *Christendom Astray*, along with *Elpis Israel* and *Eureka* by John Thomas, M.D., furnish full details as to creed.

Christchurch, a parliamentary and municipal borough of Hampshire, at the head of the estuary formed by the Avon and Stour, 24 miles SW. of Southampton by road, but 33½ by rail. The noble church of an Augustinian priory, founded here in 1150, is 303 feet long by 101 across the transept, and includes every style from Norman to Perpendicular. Special features of interest are the splendid Early English porch, a monument to Shelley, a beautiful rood-screen, and the chapel built by Henry VIII.'s victim, Margaret, Countess of Salisbury. Little remains of the domestic buildings of the monastery or of the Norman castle. Christchurch possesses one notable specialty, the making of watch and clock fusee-chains. The harbour has high-water twice every tide. The parliamentary borough, 22,350 acres in area, comprises the favourite watering-place Bournemouth. It returns one member to parliament. Pop. (1851) 7475; (1881) 28,535; of municipal borough (1881) 3260. The latter received a charter of incorporation in 1886.

Christchurch, capital of the provincial district of Canterbury, in New Zealand, situated on the river Avon, about 8 miles from Port Lyttelton, with which it is connected by rail, the tunnel through the Port Hills being the longest in New Zealand; it has also railway communication with Dunedin and with the north. The chief public buildings are the government offices, museum (with many specimens of the Moa, q.v.), cathedral (a reproduction of that of Caen in France), and hospital. There are numerous banks and insurance offices; and among the public schools are Christ's College, a high school for boys, and a high school for girls. The water-supply is derived from artesian wells. Two parks and the Government Domain afford ample pleasure-grounds. It is the centre of a great grazing district, and has also flourishing manufactories. Boot manufacturing is one of the chief industries; there are several newspapers published here, and the city possesses steam tramways, theatres, social and athletic clubs, and a corps of volunteers. The founders of the colony named each of the streets of its capital after an English diocese. An earthquake in 1888 damaged the cathedral and other buildings. Pop. (1888) 15,265; with Sydenham and the suburbs, about 30,000.

Christening, a term often used as equivalent to Baptism (q.v.).

Christian II., king of Denmark, Norway, and Sweden, was born at Nyborg, in the island of

Fünen, in 1481, and mounted the throne of Norway and Denmark in 1513. His marriage in 1515 to a sister of the Emperor Charles V. did not extinguish his love for his mistress Dyveke (q.v.), whose sudden death he avenged with his native savagery. In 1520 he overthrew at Bogesund the brave regent of Sweden, Sten Sture the younger, and thereafter was crowned king. But his ferocious passions, and especially his treacherous massacre in the Stockholm 'blood bath' of the foremost men in Sweden (November 8-10, 1520), roused such a spirit of opposition in that country that he was speedily driven out by the young national leader, Gustavus Vasa, himself the son of one of his victims. In Denmark also a popular revolt drove Christian for refuge to the Netherlands, and placed his uncle Frederick I. upon the throne. Encouraged, however, by the Catholic party in the Netherlands, and assisted by Charles V., Christian landed in Norway in 1531, but at the battle of Aggerhuus next year was totally defeated, and spent his remaining years in imprisonment at Sonderburg and Kallundborg, where he died in 1559.

Christian IV., king of Denmark and Norway, and Duke of Sleswick-Holstein, the son of Frederick II., born at Frederiksborg, in Zealand, 12th April 1577, and elected successor to the throne in 1588. He assumed the government of the duchy in 1593; of the kingdom in 1596. His first war with Sweden (1611-13) ended in an advantageous peace; his second (1643-45) cost him much of the territory across the Sound. Christian's share in the Thirty Years' War was brief and inglorious. In 1625 he became chief of the Protestant league, but his disasters so damped his ardour that he was fain to retire from the struggle in 1629 under cover of the peace of Lübeck to make room for the great Gustavus Adolphus. His indefatigable labours for the improvement of his country were more successful. He strengthened its maritime power; extended its commerce as far as the East Indies, where he obtained the first possessions; and by restrictions upon the Hanse towns, greatly increased the inland trade of the country. His legislative and financial reforms, together with his love and patronage of the arts and sciences, gained for him the affection of his people. Spite of his ill-success in war he has become a hero in the national folk-songs; the well-known ballad, *King Christian stood by the lofty Mast*, commemorates his heroism in the sea-fight with the Swedes before Kiel in 1644. His name is preserved also in the Norwegian towns Christiansand and Christiania, and in the latter city a monument to his memory was erected in 1880. He died at Copenhagen, February 28, 1648.

Christian Brothers. See SCHOOLS (BROTHERS OF CHRISTIAN).

Christian Connection, or UNION, an American religious denomination which originated about the beginning of the 19th century, in North Carolina, in Vermont, and in Kentucky and Tennessee, on the basis of the Bible as the sole authoritative rule of faith and practice, with open fellowship to all Christians of whatever creed, personal piety being the only test of qualification for membership. Most of the members are now Anti-trinitarians and Baptists. Their special organs, the *Herald of Gospel Liberty* and the *Christian Sun*, are widely read. The number of churches in 1887 was 1500; of ministers, 550; and of members, 120,000.

Christiania, the modern capital of Norway (the ancient capital is Trondhjem, 'home of the throne,' where the kings are still crowned), 59° 56' N. lat., 10° 50' E. long., is built on the northern end of the Christiania Fiord. Its population in

1888 was about 90,000, or with suburbs, 130,000. Estimated increase, 2000 annually. At the beginning of the century it was but 10,000. Christiania is named after Christian IV., who commenced building it in 1624 after the destruction of the ancient city of Oslo by fire. Christiania is the seat of the national parliament (the Storting and Lagthing), of the High Court of Judicature, and of the National University, which has 46 professors and above 1000 students who are educated free, with the exception of a small entrance-fee. Connected with this is the students' garden, a library of about 250,000 volumes, a very well-arranged botanical garden, zoological, zootomical, botanical, and ethnographical museums, and a cabinet of coins and medals, chemical and physical laboratories, and observatory. The Meteorological Institute, established in 1866, is in systematic telegraphic communication with British and other European observatories. The king of Sweden and Norway has two palaces here, one in the city near the university, and one, Oscarshall, beautifully situated two miles from the city on an eminence overlooking the fiord, and containing Tiedmand's celebrated pictures of Norwegian peasant-life. There is a national picture-gallery, and a very interesting museum of northern antiquities. The Dom, or Cathedral, and the Trefoldigheds Kirke ('Church of the Trinity'), are the principal ecclesiastical buildings. The *Dampkjøkken* ('steamp-kitchen') is an interesting institution for providing cheap and substantial dinners to working-people. The old fortress *Akershus Fæstning* still remains, and is used as a promenade, but has little military value. Among other public buildings are the Houses of Parliament, the civil and military hospitals and infirmary, lunatic asylum, penitentiary, two theatres, the Freemasons' Hall, and several banks. The staple industry of Christiania is its shipping trade; it is the central emporium for the south of Norway. Its chief export is timber. A considerable industry has recently become developed in the brewing and export of *Christiania öl*, a sort of lager beer, with resinous flavour, largely consumed throughout Norway, and exported to England and other parts of the world. The minor manufactures are cotton, canvas; engine-works, nail-works, and paper-mills, the latter rapidly growing by the use of wood-fibre from sawmill waste. There are many good hotels of recent establishment, and a considerable business is done in connection with the visits of British tourists. Cariole-making is one of the industries thus developed. There are good shops, in all of which English is well spoken; and the city has considerable printing and publishing establishments.

Christianity is the religion of which Jesus Christ is not only the founder but also the object, since it is by him and in him that man recovers his union with God by an effective reconciliation. We have thus determined in a general manner its true character, and marked the difference that exists, as we shall prove, between it and all the religions which preceded it. But first we must justify our definition. The only way to get a sure grasp of the leading thought of a doctrine and a religion is to trace it to its origin, and to seize it at its source, before the stream has had its current troubled with the foreign elements that mingle with it. Now about primitive Christianity we possess a number of documents which are at least authentic, whatever the authority we attribute to them from a doctrinal point of view. Confining ourselves to those documents alone, whose authenticity is not disallowed by the most negative criticism, we have in the epistles of Paul to the Corinthians, the Galatians, the Romans,

and the Thessalonians, a testimony to primitive Christianity which falls between the year 55 and the year 64 after Jesus Christ. It emanates from an apostle who had been in direct contact with the earliest associates of Christ, with those who had both seen and heard him. The first three gospels, in which an historical basis is generally recognised in what concerns the actions as well as the discourses of Jesus, point back to the same date. We are thus led back to the very origins of Christianity. Moreover we recognise in the church of the earliest period made known to us, whether in the Acts of the Apostles or in writings as authentic as the letters of James and those of Peter, the living impress upon simple and honest hearts of the direct remembrance of Christ, like the track marking his passage across the earth. Here our concern is not more to determine the true character, the essence of Christianity, than to find out in those documents the real meaning of the religion of the gospel as it presents itself to us. It is undeniable that if it claims to carry to the world a revealed doctrine, revealing completely the true nature of God as well as that of man, and the normal relations of union between them, it attaches that doctrine to a personality considered not only as the organ of the revelation, but as its object. We have thus the right to assert that Christianity is Jesus Christ, without fearing to detract anything from the attributes of God, for Jesus Christ is his ambassador, his son, the sole mediator between God and man—in one word, the Redeemer, the Saviour, as his name implies. He has never ceased to require faith in himself as the means of again finding God by him. Fragmentary quotations on this point are vain. The whole gospel demands this faith in his person, and St Paul sums it up in the words addressed to the Gauler at Philippi: 'Believe on the Lord Jesus Christ, and thou shalt be saved' (Acts, xvi. 31).

Christianity is herein distinguished from all other religions. The revelation which it brings to the world is something other than a supernatural communication of a transcendent doctrine about God, and about our origin and purpose in the world. It consists essentially in a great work accomplished by a single person—a work which is the supreme manifestation of the holy love of God. The mere exhibition of this divine work casts a bright light upon God as well as upon man, and results in a doctrine which implies a complete metaphysic, a complete anthropology, and an entire system of ethics, as well as far-reaching views on the history of the human race in its terrestrial development and in its future destiny. For had it been otherwise, Christianity must have contented itself with communicating to us the outward fact without explaining it—without making us grasp it by its inward side in its profound significance; which would have been to alter its nature completely. It none the less remains true that for Christianity doctrine is only a secondary and complementary element—the interpretation of the fact of the great work, which is its first object. This is why it addresses itself before everything to the heart and to the conscience, although at the same time it opens up to the intellect the vastest possible horizons. As soon as we deviate from this divine realism, we make Christianity fall into an intellectualism which chills it while perverting it; and we substitute for it the parching formulas of a scholasticism which at all times and in all churches has caused it to leave its banks and diverge into new and widely different channels.

Let us further consider that divine work accomplished by Christ for the salvation of the world, which constitutes the essence of Christianity, without lingering to discuss its proofs, which

belong to the province of apologetics. This word salvation, if we take it in all its fullness, comes before us as its principal and even sole subject. 'The son of man,' says Jesus, 'is come to seek and to save that which was lost' (Luke, xix. 10). This one word contains within itself the whole gospel, and alone explains to us why it has been specially called *good news*. This is its true significance, if we leave aside entirely its theological development. Humanity is not in its normal condition; it is lost by its own fault—through having broken by voluntary revolt the bond which at the beginning united it to God as made in his own image, and which was intended ever to become closer through the voluntary obedience it was invited to offer in the mysterious probation of its free-will. Incapable of rising again of itself, it must needs be sought out by compassionate love like a wandering and lost sheep, for the sake of being lifted up and brought back to God. This is what the Son of Man has done in agreement with the offended Father, who has had compassion upon him. Although by a saving act of his own good pleasure God has pardoned the sinner, he has not abrogated the laws of moral order. These laws demand no vengeance unworthy of God, but merely a reparation—a retraction of sin involved in an essentially moral expiation. Such an expiation can consist only in a perfect obedience, complete even to the length of accepting in a voluntary sacrifice the consequences of the original revolt. This is what the Son of Man, who was also the Son of God, has willed and has accomplished. He has died for the sins of the world, and risen again for its justification; and the cross on which he has accomplished this reparative work rises before us for ever as the symbol of a reconciliation, which each man in his turn must appropriate to himself by an act of faith uniting him to the sacred sufferer.

Christianity is thus pre-eminently the religion of redemption and of the redeemer. It has introduced into the world the grand reparative influence of a victorious love, inaugurating in Jesus himself an unceasing struggle; for that reparative influence must struggle constantly against the powers of evil, which are not magically suppressed. But this reparative work cannot consist alone in the salvation of individual souls; to be worthy of God it must strive to restore all that the original fall has blighted or destroyed—to make the fallen creature realise all his lofty destiny—that is to say, to reconstitute in man all the greatness kept in store for him, and to give him up without reserve to God, making the regenerating spirit penetrate into every sphere of his activity as into all his faculties. Hence the wide mission of Christianity to purify and raise everything that is human in the most diverse spheres of society, from the institutions which regulate the relations of men to each other to the highest culture of the intellect. This restoration of man after the divine type is the continuation and application of the redemptive work of Christ, which, after having had for its first intent to form in the Church a society of believing souls, pardoned and saved, called to work directly for the salvation of all that is lost, next radiates outwards into all the departments of human activity. It is in this enlarged sense that we must understand the kingdom of God which the Saviour came to found upon our sinful world, and of which the progress goes on only at the price of an incessant struggle, which will continue to the end of time. But this general advance of the kingdom of God in its widely human extension is always proportionate to its internal development within his Church, which keeps

and cherishes the central hearth of the divine life, whence emanate all light and heat.

We know in a general manner what the vast influence of Christianity has been in the world for eighteen centuries. We may say that the cross of Calvary has divided history; we find its luminous track marked everywhere. It has renewed society in the very depths of universal decline without ever neglecting its first task, which is to lead the souls of sinners to Christ. Spiritual conquests count upon no more than this. But these victorious struggles have not been pursued without many dangers, no little resistance and as much dark uncertainty, which have sometimes had the effect of altering Christianity for a time, at least in its historical realisations, for its high ideal has never ceased to soar with serene radiance in the eternal gospel. It may be put under a bushel, but it has never been possible to extinguish it or to change its form. It is this inherent recuperative power that admits of the renewal and elevation again of Christianity, however much it may have been debased. To illustrate the difficulties and the opposition which Christianity encountered upon its way, we must first carry ourselves back to the condition of the world at the time of its first appearance, and understand the spiritual influence of the great religions it found at that time before it. There is no better means of establishing its originality and recognising all the gains it has brought to humanity, than to bring into the light its true relation to the religions of the past. These religions fall into two types of very different nature and very unequal value; Judaism, and its antagonist, Paganism, comprising a considerable number of particular religions presenting one common character in spite of well-marked differences.

The assertion is often made in our day that Christianity was at first a mere development of Judaism, and that it was by combining with elements borrowed from the religions and the philosophies of the ancient pagan world that it assumed its final form. But this explanation will not stand an impartial examination of the actual facts. Undoubtedly there exists a real relation between the new religion and those which preceded it. For how could it be otherwise, since on its own showing it came to accomplish that which had been asked for, expected, and longed for by the human soul under every sky, as well as positively promised on the soil of Judea by direct revelations. If Christianity were only a religious doctrine, its originality might be disputed by adducing the basis of belief which it has in common with the anterior religions, although here too it manifests a splendid superiority. But as has been shown, it is more than a body of doctrine—it is an immense work of reparation effected by its founder. In that respect it cannot be compared in anything with what has preceded it, and there will always be between it and the noblest intuitions of the philosophy of a Socrates or a Plato, or the sublimest oracles of an Isaiah or a Jeremiah, that insuperable distance which divides a hope and a desire from its effective realisation. If we consider somewhat more closely its relations to the religions which preceded it, stripping it in this manner of that which constitutes its essential originality, we find at once that that relation assumes a quite peculiar character when the religion of the Old Testament is concerned. Here there is direct preparation under the form of a series of positive revelations. It was necessary in the first place that the cradle of the Messiah should be deposited upon consecrated soil—consecrated indeed, although darkened under the veil of idolatry; next, that there should be found there a chosen people to represent man in the expectation of,

and the desire for, a true Messiah. For in order that the Saviour might accomplish his work of reparation in the name of the human race, it was necessary that he should be waited for by a chosen people, such as could be formed only in a nation separated from the pagan world, and subjected to a particular moral and spiritual education under special divinely sanctioned institutions. Greatest of these was the law of Sinai, intended to awaken in the heart sorrow and hatred for sin. Prophecy completed the work of preparation by announcing to hearts pierced through by the sword of the law the coming of him who was to restore all things again, whose work was prefigured by the priesthood of the sons of Aaron and the sacrifices offered to God most holy. These special institutions were proper only to the period of preparation which was called the Old Covenant. Everything they contained that was exclusive and peculiar must disappear when the period of accomplishment had succeeded it.

The Old Covenant itself was aware of its transitory character, for above all its institutions there soared a promise of enlargement which God gave to the father of the chosen race on the day when he bade him leave his country and his kindred: 'In thee shall all the families of the earth be blessed' (Gen. xii. 3); and prophecy was but one long and splendid enrichment of the promise: 'I will also give thee,' he says, a Messiah 'for a light to the Gentiles, that thou mayest be my salvation unto the end of the earth' (Isa. xlix. 6). As soon as the reconciliation has been consummated between man and God by the sacrifice of Calvary, the wall of separation between Israel and other nations is broken down; the barriers between a powerless priesthood and the simple faithful who participate in the priesthood of Christ fall down; and sacrifices which make no expiation disappear before the only sufficient offering. You are kings and priests, says the apostle Peter to the early Christians (1 Peter, ii. 9). The religion of humanity, which is the religion of the soul, supersedes the exclusive religion of the circumcised people—the religion of the letter which killeth; and this splendid enfranchisement is but the consequence of the redemptive work of Christ which faith assimilates. All this glorious liberty is included in the words: 'The just shall live by faith' (Rom. i. 17).

It was the mission of Paul, the former Pharisee, the grand freedman of Christ, to set free the new religion from the bonds of Jewish legalism; called as he was by a divine revelation to draw all the consequences from the teaching of the Master. He formulated the charter of this freedom in two sentences, stamped with a kind of divine genius: the first, 'The law was our schoolmaster to bring us unto Christ, that we might be justified by faith' (Gal. iii. 24). Both its lofty mission and its powerlessness are here recognised together. The second is: 'Before Christ there is neither Greek nor Jew . . . but Christ is all, and in all' (Col. iii. 11). Thus the religion of humanity rises on the ruins of the national religion. We see the New Covenant striking its roots deep into the soil of that Judæa whence cometh salvation (John, iv. 22), but growing like a great tree capable of lodging in its branches all the birds of heaven; and all its liberal and blessed expansion but brings us back to the work of the Redeemer, as St Paul asserts in the words: 'Stand fast therefore in the liberty wherewith Christ hath made us free' (Gal. v. 1).

If we pass from Judaism to the religions of the ancient pagan world, at least to those developed in countries where they came into direct contact with Christianity, we find that they also had their preparation. In the first place, there is not one

human soul which has not had engraved upon it the divine law, as St Paul recognises: the Gentiles, says he, 'show the work of the law written in their hearts, their conscience also bearing witness, and their thoughts the meanwhile accusing or else excusing one another' (Rom. ii. 15). In the next place, God has not ceased to speak to them by the grand spectacle of the world itself, and of the heavens in which his invisible perfections may be seen as with the bodily eye (Rom. i. 20). Finally, if he has not granted them direct revelations, his spirit has constantly breathed upon them as it breathed upon the confused waters of chaos from which was to emerge a world. After all they belonged, as St Paul says again, to the offspring of God (Acts, xvii. 29), and there was not a single man among them who had not in him a ray of that light of the world 'which lighteth every man that cometh into the world' (John, i. 9). The need of a renewing work meets us again everywhere in the very heart of Paganism. There is no nation which has been without its priests and its sacrifices, and which has not sought that atonement for which the human conscience has always longed. But that did not hinder the pagan world from continuing to be sunk in idolatry, for it fell under the dominion of a Nature which it deified. Hence its dreadful errors equalled only by its dreadful corruption. Yet it never ceased to seek for God, groping blindly in the dark (Acts, xvii. 27). The moral conscience which had never been stifled reacted incessantly against the deadening influence of the nature-religions; it called for a God greater than those which Paganism had fashioned for it; it had its sublime aspirations which never ceased to re-echo through the pagan night one long penitential psalm, which, sung in the plains of Chaldaea, sometimes became a true supplication to the future Saviour. 'I turn from every side,' says the son of Vedic India to his god, 'desiring to know my sin. Absolve us from the sins of our fathers, and from those which we have committed in our own bodies' (*Rig Veda*, vii. 86).

The preparation of the pagan nations consisted in their being made to experience their inability to find salvation in their idolatrous religions. We may consider that preparation as finished, when out of the ruins of their old idols they raised that altar to the unknown God which St Paul recognised as the symbol of aspirations all the more ardent the more they had been deceived, and the more general the decline in the world around. The converted pagans found that peace for which they longed at the feet of Christ. They gave up without difficulty their own peculiar rites—that priesthood and those sacrifices which had availed but to express and stimulate their desire for salvation without satisfying it. For them, too, the exclusive and national character which clothed religion before the revelation of God's universal fatherhood needed to be expanded. For the religion of humanity to supersede the various religions of the soil, it was necessary not only for the Jew to renounce his exclusive theocracy, but also for the son of Paganism to recognise that the kingdom of Christ, not being of this world (John, xviii. 36), ought not to be incorporated with the state as a thing that belonged to a particular people. We see that Paganism, some admirable ideas alone excepted, brought nothing to Christianity but aspirations frustrated and yearnings unsatisfied. From the doctrinal point of view, even its noblest philosophies had been falsified by the influence of the nature-religions. Platonism itself with all its idealism ended in oriental dualism, for unable to triumph over evil, it identified it finally with matter under a fatalism whence man could escape only by an

asceticism of which the Buddhist annihilation is the logical consequence. It is this which for ever distinguishes the Christian metaphysic from all the Greco-oriental speculations comprised in the system of the Alexandrian Philo. To prevent any confusion between Christianity and Hellenism it is sufficient to read these words in the prologue to the fourth gospel: 'The Word became flesh.' Presented thus according to its primitive type, the religion of Christ appears before us in its true character and its incontestable originality; and herein rests its power. Were we to see in it only a synthesis of all the anterior religions, we should have in Christ only a kind of composite idol enshrined in the last of the pagodas; and we could not connect it with that primitive Christianity which alone is true, and which remains for all time in the faithful image it has left us of itself in the sacred volume which makes it live anew in its first and authentic manifestation. Thanks to that book we can always trace it back to its source, and mark the point of departure between what it is in itself, and the superfluous accretions which have changed it.

For it was impossible that Christianity should make no deviations once it had begun to float upon the stream of history. These were rendered imperative by its being imposed by authority upon successive generations like a dead letter—the most serious of all changes to which it could possibly have been subjected, for it is before everything the religion of the spirit and of liberty. The purpose of history after its own modification through the influence of Christianity was precisely to make it penetrate to modern humanity in a free assimilation, but that assimilation involved the possibility of all its stumblings, its failures, and its obscurities; without, however, the true Christian spirit ever ceasing to struggle against error to bring back the Church to its original type. Let us not forget that the effects of Christianity radiate outwards far beyond the immediately religious sphere; through an influence direct and indirect by turns it strives to re-establish human society upon the type of justice and love—a result which certainly forms it into a part of the kingdom of God. Mere social progress not infrequently advances religious progress, as it binds fewer burdens on the individual conscience, and appears for that reason the more easy. We cannot give more than a rapid sketch of the deviations as well as the victorious struggles of Christianity from its beginning to our own day. To explain its deviations it is sufficient for us to recall its leading thought, which is also its great power—emancipation, for these invariably tend to the alienation of the freedom in which the gospel has made us free. Christ has freed man from all the burdens under which he was bowed down, and first of all from that of sin, by his redeeming work alone. Whenever man turns aside from this, whenever he ceases to believe in a salvation which is the free gift of God, apprehended by faith, he girds on again his ancient chains, he seeks for mediators in a new priesthood, returns from the New Covenant to the Old, and restores anew the theocracy; in one word, he becomes again a Jew. This is the whole history of the formation of Catholicism, the real cause of all the slavery which it has caused anew to weigh upon the freedmen of Christ.

On the other hand, the return to Paganism takes effect whenever for the gospel of the redemption we substitute a purely philosophical speculation. The digression to the left is no better than that to the right; it is even worse, for it ends in a parching rationalism which cannot long rest on the slope downward to pantheistic naturalism. We shall limit ourselves to characterising the principal

periods of the history of Christianity, in each of which we find the battle arrayed between its most faithful representatives and the promoters of tendencies whether towards Judaism or Paganism.

Already in the apostolic age the struggle had begun, for we know that it needed the apostolate of Paul to bring down the Church from its high chamber, to cast aside the swaddling clothes of its cradle, and come gradually to the point of renouncing Judaic exclusiveness. What a combat the great apostle of the Gentiles had to wage against the survivors of the synagogue who wished at any cost to hinder the grand liberation of souls, and at the close of his life against the first representatives of pagan speculation, the Gnostic heretics of Colosse and Ephesus! Beyond doubt he was victorious, and when his noble head fell under the axe of Nero's executioner, it might have been said of him that though dead he would speak until the end of time, ever uttering anew his great cry for liberty, for the freedom of the Church from all its bonds through justifying faith.

The first period of the history of Christianity after the death of the last apostles extends from the 2d century to Constantine. It is an heroic age. The mission of Christ extends over all the empire, and fashions a whole people with their own consent. Persecution rages without intermission, but the blood of the martyrs is the seed of the gospel. The struggle goes on also in the world of thought. The Gnostic heresies mark the reaction of the pagan spirit; they are refuted by a powerful polemic. The apologetic writings of Justin Martyr, of Irenaeus, of Clement of Alexandria, and of Origen, breathe the most living and the largest faith. The most important social reforms, as the elevation of woman, the respect due to the man in the slave, are realised at the family hearth. But the gravity of the struggles against heresy, and the questions of discipline arising out of persecution itself for the restoration of such Christians as had wavered, tended to strengthen ecclesiastical authority in an exaggerated degree to the detriment of the primitive liberty. That tendency was aided by a certain weakening of the dogma of justification by faith, despite the struggles of Origen and Tertullian against the innovators.

The second period extends from Constantine to the establishment of the papacy. Christianity became the religion of the state when the Cæsar of Byzantium granted it his burdensome protection, but it still retained within it its generous sap. In spite of the authority of St Augustine faith in the free grace of God became more and more obscured. The discussions raised by Arianism more and more gave the foremost place to a Christian theodicy which resulted in a subtle divine metaphysic elaborated by the great councils of Nice, of Constantinople, and Chalcedon. These councils constituted a completed novel central authority within the Church. At the same time the old hierarchy was re-established to govern flocks cast by their birth itself into the fold of the Church, and the crook of the shepherd became the symbol of a despotic authority. The Bishop of Rome acquired a primacy that ever grew greater, until when the floods of barbarian invasion had submerged the old Roman government, the papacy became incontestably the chief centralising power. It had a high regard for social progress, and the Christian mission continued its conquests; but unhappily after its union with the empire the Church began to employ forcible constraint against its enemies both without and within. Spite of many a noble protest Catholicism took the place of the primitive Christianity, and suppressed all its liberties. It was as if the dethroned Jewish theocracy had thus revenged itself for its down-

fall; yet the enslaved Church continued to preserve the treasures of piety. Monasticism became the right arm of the papacy, and rendered it the most precious service in the education of races still rude and indeed hardly escaped from barbarism. With Gregory VII. the great transformation was completed, and the new theocratic organisation appeared in all its glory. No one can deny that under the given conditions it rendered precious services. It was still Christianity, however disfigured, to which Europe owed its alleviation from the barbarism that weighed upon it. To it alone the weak and the oppressed owed it that they were not crushed.

It is impossible to do more than characterise briefly some of the most prominent features of the middle ages and the Reformation. In the middle ages we mark the immoderate expansion of the religious and social omnipotence of Christianity, manifesting itself in the Crusades and the momentary subordination of the state to the Church after memorable struggles; and in consequence of that very temporal primacy of the Church we see it diverge more and more from its primitive type. It has quite decidedly become a new theocracy, and as has ever been the case the progressive diminution of its liberties coincides with the complete subversion of the grand doctrine of justification by faith. Salvation by works replaces salvation by grace, the supposed merits of glorified saints are purchased for the benefit of sinners, and finally indulgences from the consequences of sin are sold for a price in money. Yet Christianity even thus disfigured and diminished still shows itself beneficent for the consolation of human misery. It produces a magnificent art. The Gothic cathedral is the symbol of its greatness and also of its formidable power. Scholasticism produces its famous theological *Summas* which are as it were the cathedrals of thought. The monastic orders founded in great numbers contribute at once to the relief of the wretched and to the enslavement of the faithful. Yet it was in some of these convents that there was developed that profound and touching mysticism which sought to find God beyond the sacerdotal hierarchy. From the 14th century onwards an ardent aspiration towards reform stirred the Church. It was the ferment preparing the great approaching renovation that was to shine forth after the great schism, which weakened the papacy by breaking it into factions. This need of reform was expressed officially in the councils of Pisa and Basel. The Reformation had already its forerunners in John Huss and Wyclif, while it was, as it were, realised beforehand in the valleys of Piedmont.

With Luther it burst forth with irresistible power. If its banner was victorious over great part of Europe it was because it bore the grand device of all Christian liberty: 'The just shall live by faith.' The liberty of the people of God was actually reconquered in principle; it founded itself as at the first days of Christianity on the certainty of salvation granted by grace and seized by faith. This doctrine of liberation dismisses all human mediators to find again the universal priesthood in the sacrificial priesthood of the Redeemer. To all tradition it opposes the sovereign authority of Christ, whom Luther calls the king of the Bible, which alone permits us to know him. Next ensued a gigantic struggle, on the one hand, between the Reformation and the ancient Catholic Church, whose usurpations linked with a mercenary conception of salvation were consecrated by the Council of Trent; and on the other hand, between Christianity and a pagan culture eager to resuscitate the naturism of the ancient world without its religious aspirations. This double struggle has reached in our day its culminating height. It is complicated

whether in Catholicism or in the churches of the Reformation by an intestine struggle which brings to an issue upon narrowed ground the two opposing elements. Thus Catholicism even after the Council of Trent saw arise within itself a movement for reform, which, rendered illustrious by the Abbé de St Cyran and Pascal, tried to elevate the doctrine of grace and to limit the papal power. That noble effort was compelled to succumb before persecution, after having done honour to the church of France. Gallicanism contrived to lay some restriction upon the papal powers, but was speedily defeated like Jansenism, from which it had separated in the 17th century while retaining the stamp of its influence.

In the bosom of Protestantism there broke out early a struggle between a conservatism which would retain as much as possible of Catholicism and a Christian liberalism whose aim it was to bring back the Church to the apostolic type. That struggle has led to the creation of different churches practising in both hemispheres with more or less fidelity the constituent principles of the Reformation, or, more correctly, continuing them and disengaging them from things inconsistent therewith. In the domain of thought the battle has been fought between the partisans of a strict dogmatism and those who would admit of theological progress without breaking in anything with the eternal gospel. We must also recognise that within the heart of historical Protestantism we have seen produced, rather more than a century since, on some questions, philosophical tendencies which are Christian only in name, and which in their extreme manifestations would introduce into the fortress the enemy that besets the walls—we mean a culture decidedly anti-Christian. The siege is being carried on to-day more vigorously than it ever was before. The struggle between Christianity and tendencies contrary to it has never been more serious. Anti-Christianity under all its forms has taken a considerable development, and seems to resuscitate in our modern so-called Christian world the old Paganism, while eliminating from it the better elements, its aspirations and foreshadowings of the religion of the redemption; for this neo-Paganism in its most logical manifestations ends in an absolute naturalism which will only admit of matter and force in the evolution of all life. On the other hand, what we call the Judaizing tendency so ready to appear in the Church on the morrow of the apostolic age, has reached in these last days the final stage of its course. The ecclesiastical policy which has brought about in succession the syllabus of Pius IX., the Encyclical *Quanta Cura* (1864), the proclamation of the Immaculate Conception of the Virgin (1854), and that of the papal Infallibility at the Vatican council of 1870, have assured the triumph of the theocratic system, while condemning everything in the bosom of contemporary Catholicism like liberty in the Church or in the heart. Nothing is further from our thought than to place Catholicism *per se* outside the pale of Christianity. We recognise in it the treasures of piety. Its charity has never expended itself over social misery more bounteously than now. Christ is loved and adored within its fold by a multitude of pious souls who find him in spite of defective forms of worship and the long chain of the sacerdotal hierarchy. We refer only to the peculiarly ecclesiastical and specific principle of Catholicism when we speak of its deplorable return to Jewish theocracy. This return is the more inexplicable as the institutions proper to the Old Covenant have no longer any reason for their existence since they have found their accomplishment in the gospel. It is impossible not to observe that there exists a real co-relation between the development of the anti-Christianity

of this renewed theocracy which breaks with all modern progress from a social point of view by its attempt to enchain thought and the conscience to a sacerdotal power. Wherever Catholicism is the dominant religion it is taken as the true representative of Christianity itself. Hence is propagated the erroneous idea that there is an opposition between the religion of Christ and social progress, seeing that all the grand principles of justice, of law, and of brotherhood, come in reality from him who has raised man in every sense by reconciling him with God. Human brotherhood with all that it implies can come only from the divine fatherhood.

We are thus right in affirming that the victory of the Catholic theocracy has been the surest means of actually turning away recent generations from a Christianity ill understood and misrepresented, and that it has in this way facilitated the progress of anti-Christianity. Happily Christianity has had other representatives who have shown it in its true character. We must recognise that even in the bosom of Catholicism are to be found grand and lofty Christian men like Lacordaire, P. Grétry, Montalembert, and Dollinger, who have not admitted the divorce of the religion of Christ from political and social progress, of the gospel from liberty. They have opposed with energy the party of religious absolutism; their eloquent testimony endures in their books, and their thought remains like leaven within the Church which they have adorned, though they failed to persuade her. We may hope that this movement for true liberty will revive sooner or later in her, all the more that the fall of the temporal power will finally bring about important moral consequences.

Whatever there may be in such forecasts of the future, really evangelical Christianity has shown itself wherever the Reformation has been planted, as the initiator and propagator of true liberalism. It is easy to prove that it was to its influence, distorted indeed and indirect, that the French Revolution of 1789 owed everything that it contained of what was true and fertile for the future. Its first adherents had breathed the air of freedom in Anglo-Saxon countries. Besides, the French Protestants, by their resistance to the intolerable persecutions of which they had been the object, had preserved in their own persons the most important of all liberties—that of the conscience. It is more important to-day than ever, in face of the rising flood of democracy, that Christians, in order to dissipate the misunderstanding which in its opposition to the gospel and to liberty favours contemporary anti-Christianity, should delight to place themselves in the van of political and social progress, and should especially take to heart the elevation of the labouring classes. This is what true Christians are now doing more and more in every country. We gladly recognise that Catholics and Protestants are vying with one another in their zeal for this great social task, which is the foremost duty of our age. We may perhaps add that the gradual disappearance of state religions, with their authoritative constitutions defining the identities between the spiritual and the temporal, need not at all tend to the disadvantage of Christianity, since it will render for ever afterwards impossible all recourse to force for maintaining the authority of doctrine, thus putting final end to an intolerance which was the most flagrant contradiction of its most essential principle. We must not forget to make allowance for the modern cessation of compulsion in religion in our estimation of the actual manifestations of anti-Christianity, which in former times was compelled to save itself by concealment or in hypocrisy, although it was possible for it to exist in large

proportions within a state, though all unseen. But now the time has come for that which was whispered low to be proclaimed upon the housetops. Yet positively the truth has everything to gain in that freedom, which, however irreverent it sometimes may be, is still due to a state of things through which the great opprobrium of a persecuting religion has been made to disappear—a result for which we can hardly congratulate ourselves too highly.

The secularisation of the state entails upon us great responsibilities, especially in what concerns the young, who are the more judiciously intrusted to the care of the Church, because everywhere they are called to form their faith without any help from the state. The vast and glorious development of the natural sciences has largely contributed to develop unbelief in the domain of speculation, under the influence of that pantheistic or materialistic philosophy which had preceded it. In the intoxication of all their scientific discoveries, men imagined that they could put God and the spirit out of the world, and recognise therein only the play of mechanical forces, the evolution of motion producing a series of existences comprising thought, conscience, and soul. The adversaries of Christianity have divided themselves more and more into two great schools: *Agnostics*, denying the possibility of obtaining the least knowledge of what is beyond our own consciousness, and *dogmatic Materialists* from whatever cause produced. We have a right to affirm that Christianity has striven victoriously against both the one and the other. First of all, it numbers in the domain of science more than one illustrious representative who has actually shown that we may enrich science while believing firmly in God. Next—and this is still more important—it has brought about the most salutary enlargement in intellects within the bosom of the most earnest Christianity. The most eminent among Christian thinkers have proclaimed the reciprocal independence of science and religion. They have recognised that the first is sovereign in its own sphere, that God has not revealed what man can discover, and that in consequence religion has not to link itself with such or such a conception of the past, as if it had therein a revealed system of science. By the happiest coincidence, illustrious savants with absolutely no connection with the churches, as Du Bois-Reymond and Virchow, have refused the natural sciences the right to make excursions out of their own domain, and to settle questions like those of the origin of life or of man. They have thus declared a perfectly rational scientific agnosticism about what concerns that problem of origins, which is specially the problem of religion. It follows from this that there may exist other processes of discovery and of experiment than those of the natural sciences in that which transcends their province. It is for Christians so to employ these as to establish the reality of a spiritual and divine world, and such of its successive manifestations in religious history as come to centre themselves in Christ.

We may say that in this way a work of great importance to apologetics has been accomplished; it has happily reflected light upon the very conception of a doctrine which is ever the more widened the less it is allowed to be shut in within any formulas of the orthodoxies of the past, in order to grasp ever the more closely the living object of belief, which is Christ, and understand the better that eternal gospel, which as we have established, is essentially a fact and a person. That enlargement which we can verify in all churches freed from the yoke of outward authority, is not only favourable to the true progress of the Christian conception, but also to its preservation. One of

the most significant characteristics of this progress in our age is that it makes more than ever of the human element in the gospel, without detracting in anything from its divinity. To the metaphysical abstractions which effaced the original character of this great past has succeeded a really historical comprehension which makes it live again before our eyes. Thus in our conception of the very personality of Christ, he has come nearer us without ceasing to be the Son of God who saves us and lifts us up again. The heart as well as the intellect finds its advantage in this evolution of Christian thought, which is a return to its original; and now, indeed, it is more necessary than ever that the fire of a holy enthusiasm and a fervent love for Christ should kindle up again in Christian souls, amid all the distractions of modern life, which has become so complex through the development of human activity in every sphere, artistic, industrial, commercial, or scientific.

It must not be forgotten that after all the chief struggle of Christianity is not against such or such a system, but against the power of evil, against sin which destroys us; and that it is above all a work of redemption, of restitution, and of salvation. It is this which distinguishes it from the two great religions which dispute with it the world. Buddhism is the religion of absolute nothingness, of *Nirvana*, placing salvation in death and in annihilation, and only retaining its millions of adherents by concessions ever more and more frequent to idolatrous fetishism. Mohammedanism is merely a materialisation of Judaism, making of its Allah a God at once terrible and indulgent, for he has only murderous rage for those who do not hasten on in the footsteps of his pretended prophet to the brutal conquest of the world, while at the same time he is full of indulgence to a life of sensuality, which after being largely satisfied on earth expects its final gratification in a sensual paradise. To reconquer the millions of men held within the grasp of these two great religions, and those who belong to fetishistic idolatry, which is a survival of prehistoric humanity, Christianity has spared no effort, and has never refused to pour out the blood of its martyrs. Therefore, everything brings us back to the necessity for a struggle without cessation, both near and far off, against the powers of evil which everywhere wage war against it.

If the dust of the battle sometimes casts a shadow over the true character of Christianity, it none the less remains vigorous and living as it was eighteen centuries ago. We recognise it, even under forms the least favourable, by the intensity of its religious life, by its love of God and of Christ inseparable from its love for man, who would perish without it. Its career of conquest, far from being diminished, has increased largely during the last century through the magnificent development of its missions abroad and at home. Its charity never ceases to multiply works of benevolence and of relief. The eye of faith discerns across the great and tremendous struggle which sums up the whole of human history, a combatant greater than the greatest and holiest of Christian soldiers—that divine hero of whom Luther says in his immortal hymn, that he fights for us and with us. It is for this reason that we say at the conclusion, as at the commencement: *Christianity is Jesus Christ.*

For a list of works on Christianity, Christian Dogma, and Church History, see the article CHURCH HISTORY and the bibliography appended.

Christian Knowledge, SOCIETY FOR PROMOTING (often referred to as the S.P.C.K.), one of the great religious associations connected with the Church of England, and the oldest of them all. It was founded in 1698, although it did not receive its present name till 1701; and had for

its objects: '(1) To promote and encourage the erection of charity schools in all parts of England and Wales; (2) to disperse, both at home and abroad, Bibles and tracts of religion; and, in general, to advance the honour of God, and the good of mankind, by promoting Christian knowledge both at home and in other parts of the world by the best methods that should offer.' These objects it has never ceased to pursue, chiefly directing its efforts to the British dominions; partaking at once of the nature of an educational association, a missionary society, a Bible society, a religious tract society, and an emigrants' spiritual aid society; and notwithstanding the operations of other great societies in these several departments of Christian benevolence, its revenue amounts to about £40,000 a year. The bookselling business in 1886-87 showed total sales of £78,730; the works published being in very various departments of literature, and including several admirable series on Early Britain, Diocesan Histories, Ancient History from the Monuments, Early Chroniclers, &c. The Protestant missionaries who laboured in the south of India in the 18th century were supported chiefly by this society, and it is now fully engaged in supplying to the mission-field throughout the world needful religious literature in the vernacular. Besides translations of the Bible and Prayer-book into numerous languages, it provides for pioneer missionaries, grammars, dictionaries, reading-books, &c., to instruct them in the languages which they will have to use.—A *Scottish Society for Propagating Christian Knowledge*, incorporated in 1709, has an annual expenditure of £5000, mainly devoted to the maintenance of schools in the Highlands and Islands.

Christian Name. See NAME.

Christiansand ranks as the fourth city in Norway, is situated near to its southernmost extremity, and built on a sandy plain at the mouth of the Otterna. Pop. (1885) 12,749. It is a garrisoned town, was built by Christian IV. in 1641, and has been the capital of its province or stift since 1684. It has several dockyards, and a good harbour much used for refuge. The steam-packets from London, Hull, Hamburg, &c. to Christiania and the north usually call here. At the mouth of the harbour is the beautiful island of Odderø, laid out with public gardens and promenades. Christiansand has a considerable trade in timber, pitch, stockfish (salted cod), fish-oil for curriers, salmon, mackerel, and lobsters, the latter chiefly for the London market. About thirty lobster smacks are regularly employed between Christiansand and Billingsgate during the season. Many thousands of white ptarmigans caught in the neighbouring districts of Lister and Mandals are shipped annually from Christiansand to England. Shipbuilding is a considerable industry. Christiansand has a cathedral and grammar-school, and is the residence of a bishop and high-bailiff and of a British vice-consul. The streets are wide, straight, and regular; the houses are built of wood and detached, presenting altogether a remarkably colonial appearance. The inhabitants are noted for their stature, said to average six feet.

Christiansfeld, a settlement of Moravian brothers in Northern Sleswick, was founded in 1772, and has 700 inhabitants.

Christians of St John. See ZABISM.

Christians of St Thomas. See THOMAS.

Christianstad, the capital of a Swedish province of the same name, on the Helge, 14 miles from the Baltic, and 351 SSW, of Stockholm by rail. Formerly it was strongly fortified. It possesses an arsenal, a school, a magnificent church, and a senate-house. Pop. (1881) 9328.

Christianstadt, the chief town of the Danish island of St Croix (q.v.), in the West Indies, on the north shore. Pop. 5500.

Christiansund (63° 10' N. lat., 7° 50' E. long.), sometimes confounded with Christiansand though 350 miles farther north, is a Norwegian coast-town (pop. 7000), built on three wooded islands, Kirkelandsö, Inlandsö, and Nordlandsö. The main thoroughfare being the sea-channels between these islands gives it a curiously picturesque character, which is heightened by the irregularity of ground on which the wooden houses are built, scarcely any two being on the same level. It has a considerable trade with Spain and Italy in salt-fish, and is a calling-place for the omnibus passenger steamers which now ply so numerous on the Norwegian coast. The chief public buildings are the grammar-school and custom-house.

Christina, queen of Spain. See MARIA CHRISTINA.

Christina, queen of Sweden, only child of the great Gustavus Adolphus, was born 17th December 1626, and succeeded her father in 1632, when only six years old. Distinguished equally by beauty and the possession of a lively imagination, a good memory, and uncommon intelligence, she received a man's rather than a woman's education, and to this may partly be attributed the many eccentricities of her life. During her minority the kingdom was governed by the five highest officers of state, the principal being Chancellor Oxenstiern. In 1644 she assumed the reins of power, and in 1650 was crowned with the title of king. She had previously declared her cousin, Charles Gustavus, her successor. For four years thereafter she ruled the kingdom with vigour, and was remarkable for her patronage of learned men, such as Grotius, Salmasius, and Descartes. In 1654, however, at the age of twenty-eight, weary of the personal restraint which royalty imposed on her, she abdicated in favour of her cousin, reserving to herself sufficient revenues, entire independence, and supreme authority over her suite and household. Leaving Sweden, she proceeded to Brussels, where she embraced the Roman Catholic religion. She next went to Rome, which she entered on horseback, in the costume of an Amazon, with great pomp. Confirmed by Pope Alexander VII., she adopted the surname of Alessandra. She next visited Paris; and there in 1657 she caused her grand equerry, Monaldeschi, who had enjoyed her entire confidence, to be executed in her own household for treason. The death of the king in 1660 caused her to hasten from Rome to Sweden; but, failing in her attempt to be reinstated on the throne, she again left the country. In 1666 she aspired to the crown of Poland, but was unnoticed by the Poles. The remainder of her life was spent at Rome in artistic and scientific pursuits. Here she died April 19, 1689.

Christison, SIR ROBERT, D.C.L., physician and toxicologist, son of the professor of Humanity in the university of Edinburgh (1806-20), was born at Edinburgh, July 18, 1797. After graduating in 1819, he proceeded to London and Paris, and in the French capital studied toxicology under the celebrated Orfila. He was in 1822 appointed professor of Medical Jurisprudence in the university of Edinburgh; and in 1832 was promoted to the chair of Materia Medica, which he occupied till 1877, when he retired. He became famous as a medical writer, and risked his life more than once in his experiments with poisons on his own system. He was appointed physician-in-ordinary to the Queen in 1848; president of the Edinburgh Royal Society (1868-73); and created a baronet in 1871; and was honoured

with a banquet and the degree of LL.D. in 1872 on the completion of his fiftieth year as a professor. During a vigorous old age he could walk, run, or climb mountains better than any of his contemporaries. He died 23d January 1882. Besides contributing papers on various subjects to medical journals, Christison wrote a *Treatise on Poisons* (1829), recognised as a standard work on the subject; *Biographical Sketch of Edward Turner, M.D.* (1837); a treatise *On Granular Degeneration of the Kidneys* (1839); and *The Dispensatory, a Commentary on the Pharmacopœias of Great Britain* (1842). See his *Life*, edited by his sons (1885-86).

Christmas, the day on which the nativity of the Saviour is observed. The institution of this festival is attributed by the spurious Decretals to Telesphorus, who flourished in the reign of Antoninus Pius (138-161 A.D.), but the first certain traces of it are found about the time of the Emperor Commodus (180-192 A.D.). In the reign of Diocletian (284-305 A.D.), while that ruler was keeping court at Nicomedia, he learned that a multitude of Christians were assembled in the city to celebrate the birthday of Jesus, and having ordered the church doors to be closed, he set fire to the building, and all the worshippers perished in the flames. It does not appear, however, that there was any uniformity in the period of observing the nativity among the early churches; some held the festival in the month of May or April, others in January, conjointly with the feast of the Epiphany. It is nevertheless almost certain that the 25th of December cannot be the nativity of the Saviour, for it is then the height of the rainy season in Judaea, and shepherds could hardly be watching their flocks by night in the plains.

Christmas not only became the parent of many later festivals, such as those of the Virgin, but especially from the 5th to the 8th century, gathered round it, as it were, several other festivals, partly old and partly new, so that what may be termed a *Christmas Cycle* sprang up, which surpassed all other groups of Christian holidays in the manifold richness of its festal usages, and furthered, more than any other, the completion of the orderly and systematic distribution of church festivals over the whole year. Not casually or arbitrarily was the festival of the Nativity celebrated on the 25th of December. One of the principal causes that co-operated in fixing this period was that almost all the heathen nations regarded the winter solstice as the turning-point of the year—the beginning of the renewed life and activity of the powers of nature, and of the gods, who were originally merely the symbolical personifications of these. In more northerly countries this fact must have made itself peculiarly palpable—hence the Celts and Germans, from the oldest times, celebrated the season with the greatest festivities. At the winter solstice the Norsemen held their great Yule-feast (see YULE) in commemoration of the fiery sun-wheel; and believed that during the twelve nights from the 25th December to the 6th January they could trace the personal movements and interferences on earth of their great deities, Odin, Berclita, &c. Many of the beliefs and usages of the old Germans, and also of the Romans, relating to this period, passed over from heathenism to Christianity, and have partly survived to the present day. But the church also sought to combat and banish—and it was to a large extent successful—the deep-rooted heathen feeling by adding, for the purification of the heathen customs and feasts which it retained, its grandly devised liturgy, besides dramatic representations of the birth of Christ, and the first events of his life. Hence sprang the so-called 'Manger-songs,' and a multitude of Christmas carols (see CAROLS), as well as Christmas dramas, which at

certain times and places degenerated into farces or Fools' Feasts (q.v.), and the custom of reciprocal presents, and of special Christmas meats and dishes, such as Christmas cakes, dumplings, &c. The favourite dish was a boar's head. The custom of decorating churches at Christmas, especially with holly and ivy, is a very ancient one. Of late it has become usual for friends to forward to one another, by post, gaily illuminated Christmas cards (q.v.), bearing Christmas greetings. The Christmas tree would seem to be traceable to the Roman saturnalia, and was not improbably first imported into Germany with the conquering legions of Drusus. It is noteworthy that 'the Christmas tree' with its pendent toys and mannikins is distinctly portrayed by Virgil (*Geor.* ii. 389): '*Oscilla ex alta suspendunt mollia pinu.*' The Christmas numbers of magazines are often at great cost rendered specially attractive; they are now issued as early as October. The Pantomime (q.v.) has a special connection with Christmas-tide. The visits of 'Santa Claus,' bearing gifts, in England and America referred to Christmas, belongs properly to December 6, the day of St Nicholas (q.v.). The French Noël is derived from the Latin *natalis* (*dies*), 'birthday.' Washington Irving's *Sketch Book* gives a charming picture of an old English Christmas.

In the Roman Catholic Church three masses are performed at Christmas - one at midnight, one at daybreak, and one in the morning. The day is also celebrated by the Anglo-Catholic Church—special psalms are sung, a special preface is made in the Communion Service, and the Athanasian Creed is said or sung. The Greek Church, the Lutheran Church, and most communions save the Presbyterian, likewise observe Christmas; while throughout England and many parts of the United States it is kept as a social holiday, on which there is a complete cessation from all business. But within the last hundred years the Christmas festivities, which at one time lasted with more or less brilliancy till Candlemas, and with great spirit till Twelfth-day, have fallen off. See Chambers's *Book of Days*.

Christmas Box, a small money-gift to persons in an inferior condition on the day after Christmas, which is hence popularly called *Boxing-day*. The term, and also the custom, are essentially English, though the making of presents at this season and at the New Year is of great antiquity. A number of interesting particulars concerning the Christmas box will be found in Brand's *Popular Antiquities* and in *Notes and Queries*. Within the memory of middle-aged persons, the practice of giving Christmas boxes had become such a serious social nuisance that tradesmen stuck up notices in their windows that no Christmas boxes would be given; and at the same time the public authorities issued remonstrances to the same effect. At Christmas 1836 the Secretary of State for Foreign Affairs issued a circular to the different embassies, requesting a discontinuance of the customary gifts to the messengers of the Foreign Department and other government servants. Since this period the practice has greatly decreased, doubtless to the improvement of the self-respect of the parties interested.

Christmas Cards, as now sold and distributed in millions during the festive season, in their various forms, are familiar to every one. The invention has been ascribed by some to the late Sir Henry Cole; by others, the credit of designing the first Christmas card in 1846 is given to J. C. Horsley, R.A. Immense progress has been made in beauty and artistic effect since the time when the popular emblems were more or less confined to Old Father Christmas, images of flowers, the robin-redbreast, or the dove. The prize competitions for designs

have also done not a little in stimulating the art. Their production is begun often more than a year in advance; and the system of sending Christmas cards, as also New-year's, Easter, and birthday cards, has created a new trade, and a new field for artists, engravers, lithographers, and printers. The quantity of Christmas cards passing through the post-office leads to congestion for a few days in ordinary deliveries.

Christmas Carols. See CAROLS.

Christmas Island, in the Pacific, is in 1° 57' N. lat., and 157° 27' W. long., with some guano deposits, and is a British possession. Another Christmas Island, annexed to Britain in 1888, lies about 250 miles SW. of Java (11° S., 105° 30' E.), is 6 miles long by 4 broad, and is composed of coral masses piled up on a volcanic substratum, part of it covered with luxuriant vegetation. There is a third Christmas Island in the Bras d'Or, Cape Breton.

Christmas Rose. See HELLEBORE.

Christophe, HENRI, king of Hayti, was born a slave on the island of Grenada, October 6, 1767. Coming to Hayti, he joined the black insurgents against the French in 1790, and, from his gigantic stature, energy, and courage, soon became a leader among them. By Toussaint Louverture he was appointed brigadier-general. In 1802 he gallantly defended Cape Hayti against the French. He and Pétion secured the overthrow of the short-lived government of Dessalines in 1806; and in 1807 he was appointed president of Hayti. Civil war commenced between him and Pétion; but in 1811 Christophe was proclaimed king of Hayti, by the name of Henri I., and ruled with vigour and not without success. But his avarice and cruelty led to an insurrection; and deserted by his bodyguard and all his nobles, he shot himself, October 8, 1820. He left a code of laws which he called the 'Code Henri,' in imitation of the Code Napoléon. See HAYTI.

Christopher, HERR. See BANEERRY.

Christopher (from Gr. *Christophōros*, 'Christ-bearer'), a saint of the Roman Catholic and Greek Churches. According to the oldest form of the legend, he is said to have lived in Syria, and suffered martyrdom under the Emperor Decius (249-251). He is said to have been 12 feet high, and of prodigious strength. In the pride of his strength he would serve only the mightiest upon earth. After being some time in the service of a king, and seeing his master's dread of the devil, he gave himself to be the devil's servant. One day, however, he saw the devil trembling before an image of Christ, and he resolved thenceforth to serve Christ only. For his penance he undertook to carry pilgrims across a broad unbridged stream. One day Christ came to him in the form of a child to be carried over, but the burden grew over heavier and heavier, until it was almost too much for him to reach the farther shore. 'Marvel not, Christopher,' said the child, 'for with me thou hast borne the sins of all the world.' In painting and sculpture the saint is usually represented with the infant Christ upon his shoulders, leaning on a great staff, and straining every nerve to support his weight (see the Monograph by Sinemus, Hanover, 1868). The various legends of St Christopher are found in a connected form in the *Legenda Aurea* (1st ed. Nürnberg, 1478; new ed. by Grasse, Leip. 1850) of Jacobus de Voragine, who died in 1292. The Greek Church celebrates his festival on the 9th of May, the Roman Catholic on the 25th of July.

Christ's Hospital, Newgate Street, London, was founded on the site of the Greyfriars' Monas-

tery, by Edward VI., June 26, 1553, as a hospital for orphans. It is usually called the 'Blue Coat School,' on account of the dress worn by the boys. This consisted of a blue woollen gown or coat with a narrow red-leather girdle round the waist, knee-breeches, yellow petticoat and stockings, a clergyman's bands at the neck, and a small blue worsted cap. The cap, however, was discontinued about thirty years ago, and the petticoat in 1865, but otherwise the dress remains unaltered. Such, with slight variations, has been the costume of the boys since the foundation of the school in the reign of Edward VI.; the persistency in it through successive generations affording a curious instance of the unchangeableness in some of the English usages. Children are admitted between eight and ten years of age, and discharged between fifteen and sixteen, according to their school position, excepting the 'Grecians' (i.e. the highest class of scholars in the hospital), of whom five are sent annually on various scholarships to the universities of Oxford and Cambridge. Altogether, about 1100 boys and 90 girls are now upon the foundation. The right of presentation is vested in the governors. These are the lord mayor of London, the aldermen, and twelve common councilmen, who are *ex-officio* governors. Besides these, all noblemen and gentlemen who benefit the hospital to the extent of £500 are governors, or 'donation' governors. Of these there are at present 264. The governors are the patrons of several churches, chiefly in Surrey and Essex. In 1887 the net available income for the purposes of the hospital, and for exhibitions and apprentice fees, was about £58,000, wholly from legacies and benefactions subsequent to the foundation. In addition the governors administer large pension charities, including the Rev. W. Hetherington's Charity to the Aged Blind, which is distributed in pensions of £10 a year to upwards of 700 blind persons over sixty-one years of age, resident and born in England. King Charles II. enriched it by £7000, with an additional annuity of £370, 10s. for the purpose of educating yearly ten boys for the sea-service. Most of the building perished in the Great Fire of 1666; but, through the generosity of the corporation of London and of wealthy Englishmen, it was soon rebuilt, under the superintendence of Sir Christopher Wren. In the course of time the new hospital fell into decay, and in 1825 a third structure was erected by Mr Shaw. The great hall of the hospital is a magnificent room, second only to that of Westminster. Christ's hospital is essentially a classical institution, Latin and Greek being the basis of education; but, to satisfy the wants arising from the changed condition of society, the modern languages, drawing, science, &c. are also taught. In 1683 the governors built a preparatory school at Hertford, where the children are trained till they are advanced enough to be transferred to the London school. The girls, however, remain here until their discharge. It can receive about 450 of both sexes. Many eminent persons have been educated at Christ's Hospital, such as Camden, Stillingfleet, Coleridge, and Lamb; more recently, Sir Louis Cavagnari, Sir Henry Sumner Maine, and others. In 1885 a scheme of reform in the administration of the hospital was issued, and received the sanction of the Education Department. According to this scheme the hospital is to be transferred to the country, the board reconstructed, and a very much larger number of girls admitted to the privileges now mainly monopolised by boys. The boys' boarding-school would have 700 pupils, the day-school 600; while a girls' boarding-school would accommodate 500, and their day-school 400. See *Annals of Christ's Hospital*, by a 'Blue' (new ed. 1877).

Christ's Thorn. See JUBBE, PALIURUS.

Chromatic, in Music (from the name of one of the Greek tetrachords or scales), is applied to notes in a melodic progression which are raised or lowered by accidentals, without changing the key of the passage, and also to chords in which such notes occur. The *chromatic scale* is one proceeding by semitones alone. Much irregularity prevails in the method of writing such progressions. The most strictly correct practice is to write only such chromatic notes as could occur in chords belonging to the key in which the passage is written.

Chromatic, in Optics, is that part of the science which deals with the colours of light and of bodies. See ACHROMATISM, COLOUR.

Chromatophores are Pigment Cells (q.v.), containing pigment granules of various colours, which enable animals such as chameleons and cuttle-fishes to change colour rapidly.

Chromatype is a photographic picture in which the paper employed has been sensitized by some of the salts of chromium.

Chromium (sym. Cr, atom. weight, 52.5) is a metal, so called (*chrōma*, 'colour') from the many-coloured compounds it produces. It was discovered by Vauquelin in 1797, in the chromate of lead, $PbCrO_4$, one of its rarer ores. As chrome iron ore, $FeOCr_2O_3$, it is extensively distributed in America, Sweden, Hungary, &c.

The metal has been obtained in several modifications, one of which is so refractory as to be infusible at a temperature sufficient to volatilise platinum, while it may be heated to redness without oxidation, and resists the action of most acids. Another variety is a powder which burns brilliantly when heated in air, and is readily dissolved by acids. The metal itself has not been employed in the arts, but many of the chromates are much used in painting and colouring. Chromium forms four compounds with oxygen, of which the chief are chromic oxide, Cr_2O_3 , and chromic acid, CrO_3 .

Chromic oxide (chrome green) possesses a bright-green colour, and is the colouring ingredient in the emerald. Owing to its indestructibility by heat, it is used in porcelain-painting; while, being non-poisonous, it is now introduced as a substitute for the dangerous arsenical green pigments which were formerly universally employed in the manufacture of wall-papers.

Chromic acid or anhydride, CrO_3 , forms dark-red crystals, containing no water. When strongly heated it becomes incandescent, and is converted into chromic oxide. It forms several classes of salts: the *Chromates*, such as chromate of lead, $PbCrO_4$; the *Bichromates*, of which bichromate of potash, $K_2Cr_2O_7$, or K_2O2CrO_3 , is an example; and the trichromates and tetrachromates, which are unimportant.

Chromate of Lead, $PbCrO_4$, is well known to artists as 'chrome yellow.' It is readily prepared by mixing a solution of acetate of lead with one of chromate of potash. When boiled with lime, its bright-yellow colour disappears, and a scarlet basic chromate is obtained, which is used in the dyeing of calico.

Bichromate of Potash, $K_2Cr_2O_7$, is prepared from chrome ironstone, by calcination with chalk and carbonate of potash, and subsequent treatment with nitric acid. It forms large red crystals, and has many uses in the arts. When added to a solution of gelatine and allowed to dry, it is found that on exposure to light the gelatin becomes insoluble, and a process based on this property has been used to some extent in photography. As an oxidising agent in galvanic batteries it is very effective, while mixed with sulphuric acid it is used in the bleaching of oils.

Chromic acid and its salts are all more or less

poisonous, owing to their corrosive and oxidising action on organic tissues.

Chrome Steel containing a small and variable percentage of chromium, is highly valued in America for its toughness and strength.

Chromes-lithograph. See LITHOGRAPHY.

Chromosphere. See SUN.

Chronicle (Gr. *chronos*, 'time') denotes a history in which events are treated in the order of time. A chronicle is understood to differ from annals in being more connected and full, the latter merely recording individual occurrences under the successive years or other dates. Most of our older histories were called chronicles, such as the *Saxon Chronicle*, Holinshed's *Chronicle*, Baker's *Chronicle*. The name is also given to two historical books of the Old Testament, and is not infrequently in modern days adopted by a newspaper, as the *Morning Chronicle*.

Chronicles, THE FIRST AND SECOND BOOKS OF THE, an historical work standing in the third part of the Hebrew canon, and recapitulating the history of 2d Samuel and the Books of Kings, with many omissions, and many additions, genealogical and other. The Hebrew name means 'events of the days'; the Septuagint entitles it *Paraleipomena* ('things passed over'); Eusebius called it a '*Chronicon* of the whole divine history'—whence its present name. First and Second Chronicles are one book, of which Ezra and Nehemiah are continuations. The last three verses of 2d Chronicles are the first three of Ezra, only the last verse of Chronicles ends in the middle of a sentence, which is completed in Ezra, i. 3. In contrast to the older histories, which were written from the prophetic standpoint, Chronicles shows a strongly Levitical tendency. Most modern scholars hold its date to be about 330 B.C. or later, at the beginning of the Greek supremacy in Asia. The most useful commentaries are by Bertheau (2d ed. 1873) and Keil (1870). See BIBLE.

Chronogram, or CHRONOGRAPH (Gr. *chronos*, 'time', *gramma*, 'a letter', or *grapho*, 'I write'), a whimsical device of the later Romans, resuscitated during the Renaissance period, by which a date is given by selecting certain letters amongst those which form an inscription, and printing them larger than the others. The principle will be understood from the following example, made from the name of George Villiers, first Duke of Buckingham:

GEORGIVS DVX BVCKINGAMIE.

The date MDCXVVIII (1628) is that of the year in which the Duke was murdered by Felton at Portsmouth. Another well-known example conveys the date in the inscription upon a medal struck by Gustavus Adolphus in 1632:

CHRISTVS DVX; ERGO TRIVMPHVS.

See Hilton's *Chronograms* (1882).

Chronograph ('time-marker' or 'recorder'), an instrument to note, within a certain fraction of a second, the instant when a particular event occurs. The most recent are electrical, now indispensable to astronomers, since the transit of a star can, by touching a stud, be noted to within $\frac{1}{100}$ th of a second of time. The typical form of the chronograph is a cylinder which revolves once a minute, and carries on its surface a sheet of paper divided all round into equal parts, indicating fractions of a second. If, for example, the cylinder is 30 inches round, it is evident that very minute subdivisions of time are attainable.

A valuable application of the chronograph is for determining the longitude—e.g. in trigonometrical surveys. Thus two observers note simultaneously the transit of a star, say at Vienna and Paris (and

that without any reference to right ascension or declination), and having telegraph as well as chronograph, determine very easily the difference of time with an accuracy never dreamt of formerly.

Benson's chronograph, by a lever movement, measures intervals of time down to tenths of a second for use at horse-races, &c. By a special contrivance the seconds hand on a horizontal dial carries ink, and marks the plate beneath at the instant when a string is pulled. Another mode of recording the exact instant of start or finish is by having a paper travel under a pencil, so that when the latter is pressed a mark is made on or near one of the cross lines showing tenths or twelfths of a second.

Other forms of the chronograph are used for determining the velocity of projectiles. The most general arrangement consists in causing the bullet to pass through a series of screens; the rupture of each screen breaks for a moment the continuity of an electric current, sets in action an electro-magnetic apparatus, and makes a permanent mark or record.

Chronology (Gr. 'time-reckoning'), the science of time, especially in regard to (1) the occurrence, recurrence, and succession of events, or (2) the duration of periods and cycles. The immense array of facts with which chronology is occupied may be distributed under two great heads—Mathematical or Astronomical Chronology, and Technical or Political Chronology. The former deals with celestial phenomena, their order and the laws of their occurrence and duration, events outside of man's sphere or influence. The latter branch deals with the whole history of our race upon this planet; and by the selection of certain fixed points in time called *Epochs*, refers to each of them the succession of social and political events occurring in the period immediately following it, and reckoned from it, which we term its *Era*. As soon as the elements of mathematical chronology were understood, political chronology had solid ground to build upon, and assume a systematic form: then a science of history became possible. A 'year,' for example, seems now an easy and natural unit of time-measurement; but for long ages the only idea suggested by the word was that of a vague, intangible period. So late even as 450 B.C. we find Herodotus expressing duration of time by the phrase 'three generations' (= a century) or 'five generations'; and in all languages we find 'six summers' or 'sixty winters' instead of so many years.

In the rudimentary stage of chronology, a nation referred its history to the lifetime of some central figure, such as the king, the tribal chieftain, &c.; of which custom we actually find a survival in our system of dating acts of parliament. The priestess of Juno at Argos was another instance; and in the Roman and Athenian republics, where the chief-magistrates were chosen annually, an event was conveniently said to have occurred 'when Plancus was consul,' or 'in the archonship of Kallixenos.' Similar to the Roman *consul* and the Athenian *archon* was the Assyrian *limu* or 'eponym,' from whose name Babylonian and Assyrian documents were dated far more frequently than from that of the reigning king. Such a chronology, however, could only be of use within narrow limits both of time and place; and at all the great centres of civilisation we find that as men's historical views widened with the national growth, they began to invent eras, some from national or political motives, others ecclesiastical, and a few scientific. Progress in astronomy, such as we find in China and Babylonia at the dawn of history, was of notable service at this stage. To the Accadians of the latter country indeed both astronomical and political chronology owe a lasting debt of gratitude. The Chinese, no doubt, show a

time computation which is apparently prehistoric, and their recorded eclipse observations prove a chronology of at least four thousand seven hundred years' duration; but if they did adopt a year measurement equivalent to our Julian system some 2000 B.C., it is certain they have exerted no influence on European civilisation compared with that of the Accadians of Babylonia, or ancient Chaldeans as they used to be named. Fairly accurate chronology in ancient Babylon begins with Sargon I., king of Agade, 3800 B.C. The earliest authentic date is that inscribed on the foundation stone of the temple to the sun-god at Sippara by Naram-Sin, son of Sargon. This was dug up by Nabonidus, who began to reign over Babylon about 554 B.C., and who says that Naram-Sin reigned 3200 years before his time, thus giving a total of 3754 years B.C. as the date of his building of the temple. Thus by the year 4000 B.C. the nation had attained to considerable advance in literature, science, and art. Much of the greatness of Babylonia, foremost in culture for centuries, was afterwards reflected in Assyria, who inherited her civilisation and learning, as in a lesser degree also did Israel. Berosus gives a list of dynasties of 120 *saroi*, or 432,000 years before the Deluge, and of eight dynasties after it, and Ptolemy's canon in the *Almagest* gives the seventh dynasty in full from Nabonassar (747 B.C.) to Sineladanos (Assur-bani-pal, 668-626). From about 2330 B.C. they used a regular calendar, with a week of seven days, and a year of twelve months, named after the zodiacal signs. Their year was of three hundred and sixty days, which probably suggested that division of all circles into degrees which we have derived from them. In astronomical chronology they had cycles of sixty years, six hundred years, and the *sar* (= 3600 years)—the factor sixty running through all their arithmetic. The great Babylonian work on astronomy and astrology was the 'Observations of Bel,' compiled at Accad for Sargon, and translated into Greek by Berosus. It was mostly a record of eclipses of the sun and moon, conjunctions and phases of Venus and Mars, the time of the new year, the names of the zodiacal signs and the divisions of the year. The famous Assyrian eponym canon, discovered by Sir Henry Rawlinson in 1862, fixes definitely for us the chronology of Assyria from 1330 B.C. to about 620 B.C.; but a fairly accurate list of kings can be made out up to perhaps 1700 B.C. Thus continuing that early pre-Semitic civilisation, the more warlike Assyrians furnish many dates of importance—e.g. 720 B.C., Sargon conquered Arabia and Syria, levying contributions from Cyprus; 705 B.C., Sennacherib conquered Phoenicia and Egypt, carrying away two hundred thousand Jews; 681 B.C., building of the great palace at Nineveh, where afterwards, during the golden age of the Assyrian empire, ruled great Assur-bani-pal (long called Sardanapalus), the brilliant patron of art and letters. The discovery, in our time, of his national library almost compensates the literary world for the loss of that of Alexandria. See BABYLONIA, ASSYRIA.

To the Chaldean astronomy we owe the Saros, a cycle of two hundred and twenty-three lunations, which is still of signal importance in calculating eclipses. To it also is due the era of Nabonassar, one of the most famous in the annals of chronology, the basis of all the computations of Ptolemy, and frequently referred to both by historical and astronomical writers—e.g. in connection both with Alexander the Great and Aristotle. From its epoch, 26th February 747 B.C., it maintained its ground till after the commencement of the vulgar era. In the same century, singularly enough, occur the epochs of two other eras which, though

of less note in astronomical chronology, are much more familiar to historical readers—viz. the Greek era of the Olympiads, reckoned from 1st July 776 B.C., and the Roman era of the Founding of the City (A.U.C.) from 22d April 753 B.C. The public games at Olympia formed an essential part of the national life to a Greek; and thus we find Xenophon refer an event to the year when Eubotas of Cyrene won the foot-race, just as in some parts of England a man will be heard saying 'Ah! that was the year Friar Tuck won the Derby!' The Olympic Games were of unknown antiquity, but the era or first Olympiad dates from the year when Corcebus was victor. Extending over a period of four years, the Olympiad (q.v.) was really a small cycle; thus the year 729 B.C. is expressed in Greek chronology as the third year of the twelfth Olympiad. The Latin epoch, the Founding of Rome, is not so accurately known as that of the Greeks; but the date assigned by Varro (753 B.C.) was accepted by Cicero and Pliny, and has been generally adopted by modern historians. Cato's date (751 B.C.) deserves note, from its use both by Livy and Dionysius of Halicarnassus: 750 was that of Polybius. Nor must we forget that all Latin writers, and many Greeks also, dated an event by naming the Roman consuls of the year. Under the empire, in 312 A.D., Constantine introduced the cycle of fifteen years, called *Indiction* (q.v.), of which, as an official mode of computation, there still remained some survival in France at the end of the 15th century. The old Roman era, however, as well as the Grecian, maintained some footing till after the birth of Christ; and the latter has even been traced to 440 A.D. = 304th Olympiad.

The Greeks had the honour of inventing the Metonic cycle (commencing 15th July 432 B.C.) of 235 lunations = 19 years, and also the Calippic of 76 years. Like the Chaldean saros, both of these cycles were used to predict new moons, eclipses, &c.

Of the Hindu or Egyptian eras there is little that affects the science of chronology. The antiquity of the Indian epics is a question purely literary; and the only epochs to record here are the descent of the Aryans to the Punjab about 2000 B.C.; the Council of 543 B.C., which inaugurated the Buddhist era, and that of 309 B.C., when Buddhism (q.v.) became the state religion. The Indian chronology has some affinity to the Chinese; and a singular refinement in their mode of computing time was their use of the sidereal year—i.e. reckoning by the return of a meridian to the same star (see YEAR). The Egyptians, on the contrary, though their year began with the rising of the star Sirius, called a year 365 days exactly, and were, therefore, compelled to use a cycle of 1461 years ($= 4 \times 365 + 1$), a most cumbrous adjustment, though simple. The week of seven days was from earliest time adopted by the Brahmins in India, and the ancient Egyptians, as well as by the Accad settlers of Babylonia already referred to.

The Jewish chronology is unimportant except from its relation to religious matters, and scarcely affords examples of any era, since *sacred* chronology, as it is called, is only partially based upon the Pentateuch. What knowledge of astronomical chronology the Jews had was derived from the ancient Chaldeans through the Assyrians, and their calendar was mainly Egyptian. Their year, like that of the ancient Greeks and modern Turks, consisted of twelve months of alternately thirty and twenty-nine days (or twenty-nine and a half on an average—i.e. a lunation), with an intercalary month once in three years, and sometimes once in two. One peculiarity of the Jewish calendar was that they divided their year into *six* seasons—seed-time,

winter, cold season, harvest, summer, and hot season—an arrangement due probably to their climatic surroundings. Leaving Egypt *circa* 1320 B.C. (so Bunsen, following Eratosthenes; others give 1330), the Jews showed some signs of national vigour in the 12th century B.C. on the decay of the Egyptian empire, and their history reached a short culmination in the reign of Solomon. When split into two small kingdoms they soon found that, although assisted by Syria and their more civilised neighbours the confederation of the Phœnician cities, they were of but little avail against the might of Assyria. By the siege of Samaria in 721 B.C., and that of Jerusalem in 587 B.C., the little kingdoms of Israel and Judah were successively overthrown, and the Jewish nation finally shattered. Having no national chronology, the Jews who returned to Palestine are found using the Macedonian era, which dates from 311 B.C., the reign of Seleucus, one of the successors of Alexander the Great. This they did in common with the Syrians and Greeks all round the Levant, and reckoned by it till the 15th century, as some Arabians are said still to do. At present the Jews, as also the Freemasons, profess to date their calendar from the 'Creation,' 3760 years B.C.

Sacred chronology, or that of Scripture, is an attempt to harmonise the succession of events recorded in the Old Testament, especially with reference to the semi-traditional or prehistoric period preceding the Exodus. There are three accounts—the Jewish, the Samaritan, and the Greek Septuagint—and their discrepancies, though referring to the same periods and succession of events, are hopelessly irreconcilable. Sacred chronology divides all time before the birth of Jesus Christ into three great periods (as in the following table); and as to the first all the texts are at variance, while in the middle period the Septuagint agrees with the Samaritan, but both differ from the Jewish reckoning by 650 years:

Period.	Jewish.	Samarit.	Septuag't.
Adam to Noah	1656	1307	2242
Noah to Abraham	292	942	942
Abraham to Jesus Christ..	2044	2044	2044
Creation to Incarnation.	3992	4293	5228

The three authorities, therefore, entirely disagree as to the total period. To complicate the confusion, all those results are given differently by different interpreters; and no less than over two hundred varying computations have been made as to the date of the creation, ranging from 2483 years to 6984. The familiar date in English books was 4004, following Archbishop Usher's reckoning. At last it became clear through science that man's duty is to strive to interpret nature, and to shrink from assigning any limit to her works as to either beginning or ending. The *Newtonian* chronology was an attempt (published posthumously be it remembered) to rectify some of the discrepancies in sacred and profane history, by combining a critical examination of authors with astronomical calculations. For example, the famous date of the Argonautic expedition was, by an ingenious application of the precession of the equinoxes, assigned by Newton to forty-three years after the death of Solomon, or 937 B.C. (Hales), a date utterly inadmissible. For the expedition, if indeed it ever took place, must have preceded the siege of Troy, which is ascribed to 1184 B.C.

The Hegra (Hedjrah) or epoch of the Moslem era is dated Friday, 15th July 622, the New-year's Day of the Arabian year, or, as others say, from the 16th. The Mohammedan year being strictly lunar—from

the primitive reckoning by months instead of years—the calendar requires several adjustments from time to time by means of tables arranged according to cycles of thirty years, of which nineteen have 354 days and the others 355. The principal festivals of the Moslems are the New-year, the birth of the Prophet, the taking of Constantinople, and the Grand Bairam (q.v.).

From these minor systems of chronology we at once pass to that of our present era, which, though begun as it were accidentally, unenforced by the authority and command of emperors, kings, or councils, seems destined soon to assert universal predominance. The Christian era (or 'vulgar era' as older writers termed it) has its epoch or point of departure determined by the Gregorian rule—viz.: 'The years are denominated as *years current* from the midnight between the 31st December and the 1st of January immediately subsequent to the birth of Christ, according to the chronological determination of the event by Dionysius Exiguus.' Now as Dionysius, the obscure author of this chronological scheme, lived in the beginning of the 6th century, there was no exact determination of the epoch; and it cannot therefore be so precisely formulated as other eras of less importance. It is generally agreed that the beginning of the era should have been fixed from two to four years earlier. Another point not generally noted is that the correction of our calendar by Pope Gregory itself wanted correction; because instead of ten days the papal bull should have enjoined an omission of twelve. His Holiness or some adviser proposed the Council of Nice as their starting-point in estimating the error already made, and reckoned therefore from 1st January 325 A.D. instead of 1st January 1 A.D. The only wonder is that his astronomers assented. It may further be pointed out that the papal reformation itself is by no means the best that could have been devised; and that long before that date, in 1079 A.D., Omar, a Persian astronomer, actually proposed a scheme which would adjust the years and days not only more exactly, but much more simply. Omar's rule, shortly, was: (1) Intercalate a day every fourth year, but (2) intercalate during the thirty-third year instead of the thirty-second. By this scheme five thousand years must elapse before a further correction is made—viz. of one day, whereas by Gregory's rule a correction of three days is necessary within four thousand years. In this connection may be noted the extremely ingenious mode by which the new style was adopted in Sweden—viz. by deciding to have no leap-years between 1696 and 1744.

From the mode of fixing the epoch of the existing era as indicated above, it is manifest that, since there is no 0 A.D. and no 0 B.C., we must diminish the sum of the nominal years B.C. and A.D. by unity to find the interval. Thus the years between 1st January 753 B.C. and 1st January 1888 A.D. are not 2641 but 2640. The epoch 1st January 1 A.D. was first, as we have seen, established by measuring backwards according to the estimate of Dionysius Exiguus in 527 A.D.; and when measured forwards from other epochs we find that our era dates from 1st January of the fourth year of the 194th Olympiad = 753 A.U.C. = 4714 of the Julian period.

That brings our subject to an era, which, theoretically at least, is the most important in the science of chronology. The epoch of our existing era is not well suited for technical purposes, as all astronomers and chronologists allow, because the birth of Christ is too recent an event; thus enhancing the difficulty of fixing the relation between the different systems, and of expressing a date or period of one era exactly in terms of

another. Therefore, just as Fahrenheit chose for his zero a mark thirty-two degrees below freezing-point, in order to avoid negative measurements, so the Julian period had its epoch fixed to 1st January 4713 B.C., a point of time antecedent to all other epochs, in order that its era should be a convenient standard to which all other chronological systems can be differentially referred. Its length is 7980 Julian or Metonic years, the product of 28 (Solar period), 19 (Lunar period), and 15 (Indiction), and thus constitutes a great cycle embracing and unifying three subordinate cycles which are constantly referred to;

because the year 4713 B.C. is the most recent date when those important periods began exactly all together. With the further development of technical chronology, and a more scientific treatment of history and ethnology, we may look for a much wider use and appreciation of the Julian period as a cycle comprehending all really historic time, and fulfilling certain astronomical conditions of the first importance. When the year of the Julian period is known, the corresponding date for any of the subordinate cycles is easily found, and conversely. We subjoin a table for the comparison of some selected dates:

EPOCHS AND LEADING EVENTS IN CHRONOLOGY REFERRED TO THE JULIAN PERIOD.

	Julian Period.		Common Date.
	Month.	Year.	B.C.
Babylonia already civilised under the Accadians.....	Jan. 1	1	4713
Vernal equinox coincident with solar perigee.....	March 21	625	4089
Eclipse observations recorded by Chinese astronomers.....		1864	2850
Aryans settle in the Punjab.....		2714	c. 2000
Palace built in Nineveh.....		3364	1850
Exodus of Hebrews from Egypt according to recent Egyptologists.....		3394	1820
Temple dedicated at Jerusalem.....	May 1	3699	1015
Greek era of the Olympiads.....	July 1	3938	776
Latin era of the Founding of Rome (Varronian epoch), A.U.C.	April 22	3961	753
Era of Nabonassar, prince of Babylon, the epoch used by Ptolemy.....	Feb. 26	3967	747
Assur-bani-pal king—golden age of Assyria.....		4046	668
Eclipse of Thales (Herodotus), identified by modern astronomers.....	May 28	4129	585
Era of Buddha.....		4171	543
Babylonia conquered by Cyrus.....	July	4176	538
Pericles supreme at Athens—golden age of Greece.....		4270	444
Metonic Cycle (astronomical epoch).....	July 15	4282	432
Reformation of the calendar by Julius Caesar.....	Jan. 1	4609	45
			A.D.
Dionysian or Christian era—epoch not proposed till 527 A.D.	Jan. 1	4714	1
Hegira, the flight of Mohammed—epoch of the Moslem era.....	July 15	5335	622
Summer solstice coincident with solar perigee.....	June 21	5959	1246
Fall of Constantinople.....	May 29	6166	1453
America discovered by Columbus.....	Oct. 11	6205	1492
French Revolution.....	July 14	6502	1789
Completion of first Julian period.....	Dec. 31	7980	3267
Autumnal equinox coincident with solar perigee.....	Sept. 21	11196	6483

The Julian period or cycle in its modern form was proposed by Joseph Scaliger, but the Greeks of Constantinople appear to be the authors of it. Its exact epoch is noon of 1st January 4713 B.C. for the meridian of Alexandria, which was chosen as being that to which Ptolemy had referred the era of Nabonassar already discussed. Scaliger has the best right to the title of father of chronology, often given to Eratosthenes.

The astronomer Laplace in recent times proposed another universal era not so practical in its bearing on political chronology. He calculated that about 4000 years B.C. the major axis of the earth's orbit coincided with the line of the equinoxes, and that in 1250 A.D. they were at right angles. In the latter year, therefore, he proposed to fix the universal epoch whence the whole world should reckon, the vernal equinox to be the first day of the first year, when the solar perigee coincided with the summer solstice. With Laplace's estimate may be compared the dates of coincidence with the solar perigee which are tabulated above.

There are many other instances of astronomical chronology overlapping and influencing political chronology. Thus, by reckoning back we are able to identify the time and place of some remarkable eclipses, such as that of Thales (see in table above), which caused the suspension of a battle between the Medes and Persians. Another striking verification was by that of Larissa, the Nimroud of Mr Layard. Scottish history furnishes another recent instance. We read that when King Haco sailed from Bergen with his Norse fleet to punish the king of Scotland, he put in at Ronaldsvoe in Orkney, which was then subject to him, and that there the sun appeared as a thin bright ring. Sir David Brewster found by computation that there

was an annular eclipse of the sun passing over Orkney on 5th August 1263, about one o'clock. Two months afterwards Haco was defeated at Largo, and Alexander annexed the Hebrides to Scotland. 'The ring at Ronaldsvoe was an evil portent.' Such verifications in chronology are dependent on the testimony of contemporary writers. Other valuable information has been derived from coins, medals, monuments, and inscriptions.

To treat adequately many of the important ramifications of our subject is here impossible, and we have therefore only passed under review the main features of the science as a whole. One department, however, of political or technical chronology deserves special attention from its interest to antiquaries and lawyers as well as to historians—viz. the method of assigning events to their respective years, or fixing their dates as it is called, either by verifying in cases of doubt, or reconciling and correcting in cases of discrepancy, inconsistency, and contradiction. How, for example, can the following dates be accounted for—all printed in the same month of the same year, 1705? In the *London Gazette* of 13th February is given a translation of which there is an abridgment in the *Edinburgh Courant* of the 19th, yet the original passage is in the *Amsterdam Gazette*, dated 22d February.

The first cause of such discrepancies is the difference of styles (see CALENDAR), which occasions seeming blunders of ten, eleven, or twelve days, according to the century. As 170 years elapsed before England adopted the new style, the chief Roman Catholic countries being followed by Poland (1586), Hungary (1587), Strasburg (1682), German Protestant States (1700), and Tuscany (1749 or 1751), all in different years, there was ample

room left for innumerable discrepancies as to dates.

Besides differing in the style—i.e. Julian or Gregorian—two nations frequently began the year at different times. A Scottish writer assigned the execution of Charles I. to 1649, and his English contemporary to 1648, though both agreeing as to the month and day; because in Scotland the year began with the 1st of January, as it had done since 1600, and in England the 25th March was still New-year's Day. Throughout Europe there was much variation in this respect, not only between one country and another, but even in the same country as between one time and another, as well as between its different provinces at the same time. The most common New-year's Days were these four—(a) 25th December; (b) 25th March; (c) Easter; (d) 1st January. Thus England used both the first and second from the 6th century to 1066; the fourth till 1155; then the second till the day after 31st December 1751, which was called 1st January 1752. Scotland used the second till 1599, when the day after 31st December 1599 was called 1st January 1600. France under Charlemagne used the first, and afterwards also the third and second till 1563. The 25th March was originally chosen by Dionysius Exiguus, the author of our present era, as being the Annunciation—exactly nine months before Christmas. A survival of its use in England appears in the annual Treasury accounts, and in preserving Lady-day as a quarter-day.

In many English documents before 2d September 1752, owing to the delay in accepting the Gregorian reformation, we find a date thus, 12th February 1704 or 1706-7, meaning 1706 if the year begin on 25th March, or 1707 if it begin on the 1st of January. This ambiguity of course only applies to days falling between 1st January and 24th March.

A third cause of error or uncertainty arose from dating ancient writings not only by saints' days and church festivals, but by some Latin psalm or other portion of the service which the clergy (who of course were generally the clerks) associated with the day in question. Thus we find as a date (15th century) 'the Wednesday next after *Deus qui errantibus*,' and (in 1610) 'the Sunday on which the church sings *Reddite quæ sunt Cæsaris Cæsari*.' A Scottish parliament of 1318 met at Scone 'on the Sunday next after the feast of St Andrew the Apostle'; and an English one of 1399 is only dated in a contemporary account by the phrase 'on Monday the feast of St Faith the Virgin.'

A special complication arose from dating documents, and especially all state papers, by the year of the king's reign, as already referred to. Even in Rymer's *Fœdera*, a work of the highest importance in English chronology, we find that from this cause many of the public papers from Richard I. to Edward IV. are misdated by a whole year. Our early sovereigns dated their reign from the coronation, and the writers of history frequently assumed that every king's succession was officially dated from the day of his predecessor's death. In the case of popes of Rome, moreover, scarcely any two of them in immediate succession, until recent times, dated or computed on the same principle; and some of them vary their methods even within their own reigns. In this connection may be noted a clerical error in the Scottish records of David II., where after his return from captivity every date of his reign is given one year short. Frequently too in public documents, both English and Scottish, we read 'King Henry,' 'King Edward,' 'King Robert,' or 'King James,' without further qualification; so that for purposes of chronology we must study the penmanship, the style and wording, the seal, and above all the names of the persons enumerated. Even then the antiquary or historian is sometimes

unable to reduce the date of an instrument or letter within a narrower range than fifty or even a hundred years.

A reference to contemporary history will sometimes fix the date. For example, there are two acts in the Scottish statute-book which are thus dated—one, 'at Aberdeen in Lent next after the coming in Scotland of Vivian the Legate of the Apostolic See;' the other, at Stirling, 'on the Monday next before the feast of St Margaret the Maiden next after the first coronation of Philip king of the French.' From these data we can assign their dates as 1177 and 1130 respectively.

Bibliography.—Sealiger's *De Emendatione Temporum* (1583); Usher's *Annales V. and N. Testamenti* (1650); Sir I. Newton's *Chronology Amended* (1728); *L'Art de Vérifier les Dates* (1818-31); Herschel's *Astronomy*; Ideler's *Lehrbuch* (1831); Clinton's *Fasti*, &c.; *Chronology of History*, by Sir Harris Nicolas (1838); Brinckmann's *Handbuch* (1882); Woodward and Cates's *Encyclopedia of Chronology* (1872); Whitworth's *Churchman's Almanac from 1201 to 2000* (1883); Brockmann's *System der Chronologie* (1883).

Chronometer, or time-measurer, is the name given principally to such time-keepers as are used for determining the longitude at sea. The mechanism of a pocket chronometer is essentially the same as that of a common watch; only the size is generally greater, and the balance-wheel is compensated for variations of temperature. See HOROLOGY.

Chronoscope, an instrument contrived by Sir Charles Wheatstone to measure the duration of certain short-lived luminous phenomena, such as the velocity of light, or the electric spark, of which the eye itself can be no judge, owing to the persistence of impressions on the eye after the cause of sensation has ceased. The phenomenon is observed by reflection in a mirror in such rapid motion that the image of the luminous object would appear to describe a circular arc the length of which must be a measure of the duration of the light. The electric spark is found by this test to have no duration, because its image in the mirror is a mere point. The chronoscope has also been used for measuring the time of flight of projectiles. By means of it Foucault even determined the difference of the velocity of light when passing through air and water, and thus deduced the corresponding indices of refraction.

Chrudim, a town of Bohemia, 74 miles ESE. of Prague by rail. It manufactures sugar, beer, alcohol, and artificial manure, and has important horse-markets. Pop. (1880) 11,886.

Chrysalis, or CHRYsalid, a term originally applied to the golden-coloured resting stages in the life-history of many butterflies, but sometimes extended to all forms of pupæ or nymphs—that is, to the second stages in the history of insects which undergo complete metamorphosis. It is the stage which results from the fasting quiescence of the generally active and voracious larva or caterpillar, and also, of course, the stage which after one or rarely two moults awakens into the winged insect or imago. During the whole or part of its often prolonged existence, the pupa or chrysalid is externally quiescent; but internally most profound structural changes are going on, which amount in many cases to a thorough reconstruction, and always result in the development of wings and sexual organs. Chrysalids vary greatly in degree and duration of quiescence, in habit, in the condition of their appendages, and in the development of external covering. The colours also vary greatly, and in some cases the golden or otherwise coloured appearance is doubtless protective. They are generally found hidden away in protected corners, or underground, or suspended from the leaves of plants. The completion of the internal

reconstruction is soon followed by a writhing restlessness, in the course of which the chrysalis frees itself from encumbrances, and emerges

Various forms of Chrysalis :

a, orange-tip butterfly; b, black-veined white butterfly; c, swallow-tailed butterfly; d, purple emperor; e, silver-washed fritillary; f, Duke of Burgundy fritillary.

into freedom and flight. Mr Poulton has made some exceedingly beautiful experiments on the effect of external surroundings on pupæ, and has shown how gilded surroundings are associated with the appearance of gilded chrysalids. See BUTTERFLY, CATERPILLAR, INSECTS, METAMORPHOSIS.

Chrysanthemum (Gr., 'gold-flower'), a genus of plants of the natural order Compositæ, sub-order Corymbifere; having a hemispherical or nearly flat involucre, with imbricated scales, which are membranaceous at the margin, a naked receptacle, the florets of the disc tubular and hermaphrodite, those of the ray strap-shaped and female, the fruit destitute of pappus. The species of this genus are annuals, perennials, or shrubby; and all have leafy stems. They are natives chiefly of the temperate parts of the Old World. *C. leucanthemum*, the Ox-eye, or Ox-eye Daisy, is abundant in fields, meadows, and grassy places of woods in Europe and North America. It has large flowers, with white ray and yellow disc. It is often a troublesome weed among hay and in pastures; being perennial, and having a creeping brittle root-stock, it is not easily extirpated. It is common in Britain, which has several other native species, *C. segetum* (Corn Marigold), a frequent weed in cornfields, which is an annual, with large deep yellow flowers; *C. inodorum* (Scentless Chrysanthemum), an annual with erect branching habit, leaves like the camomile, and white flowers; and *C. parthenium*—*Pyrethrum parthenium* of some botanists—Common Feverfew, a perennial, probably originally spread from cultivation, but now at least apparently indigenous to a great part of Britain. Of the latter, the *Golden Feather*, so commonly used in designs in the flower-garden, and a compact free-flowering form with double flowers, are two useful and well-marked varieties. From *C. inodorum* has also recently evolved a variety with pure white double flowers, of great value to those who cater for cut flowers, the colour and form being desirable and the crop enormous. The Paris Daisy or Marguerites, which have recently become so popular as greenhouse and bedding plants, are forms of *C. frutescens* and *C. pinnatifidum*, the latter a native of Madeira, the former of the Canaries. The old-fashioned

yellow and white chrysanthemum of our cottage-gardens is *C. corduarium*, a native of Sicily and North Africa. *C. carinatum*, a pretty annual species from Barbary, is sometimes seen in gardens in this country treated as a tender annual. The most favoured species, however, with gardeners of this and other countries is *C. sinense*, sometimes also named *C. indicum*. It was introduced in 1764, and has increased in varieties immensely since then. In 1832 there were only about forty known; now they are to be reckoned by hundreds, and the numbers are yearly being added to. Long before it was known in Europe the gardeners of China and Japan were enthusiastic cultivators of the flower; and it gives its name in the latter country to the highest order of honour—'The Order of the Golden Flower.' The colours are exceedingly various and beautiful, and the form of the flower-heads in some varieties is marked by the most perfect symmetry, while in others it assumes a medusa-like character, with numerous twisted thread-like florets of several inches in length. The circumstance that it may be had in flower during the late autumn months and far into winter, coupled with its profuse flowering quality and its simple cultural requirements, renders it a universal favourite. Cuttings are struck in November, December, and January. They require no heat, but merely protection from frost, and till they strike root they must be kept in a close case away from draught. The soil they delight in most is a rich loam, with decomposed manure, a third of the latter to two-thirds of the former. They should be placed out of doors from May till the beginning of October, when they must be housed to protect them from frost. See Burbidge, *The Chrysanthemum: its History and Culture* (1884).

Yellow Chrysanthemum.

Chryselephantine (Gr., from *chrysos*, 'gold,' and *elephas*, 'ivory'), the art of making statues jointly of gold and ivory, was extensively practised amongst the Greeks. It developed out of the art of wood-carving, the draperies of the wooden figures being gilded for ornament, while the faces, hands, &c. were painted white. Then the uncovered parts of the body came to be made of marble, producing *Aceroliths* (q.v.); and ultimately ivory was used, with gilding or gold-plating. The bulk of the figure continued to be made of wood, or wood and clay; thin gold plates were fastened over the parts intended to represent clothing, while on the fleshy parts small plates of ivory were skilfully laid. The colossal works executed by Phidias in the time of Pericles are the most famous of this class, the greatest being the *Athene* on the Acropolis, which represented the goddess in armour, covered with a long robe, and the famous Olympian *Zeus*, executed in the same materials (see *Colossus*). The combination of gold and ivory was chiefly used in statues of the gods; hence it was regarded as blameworthy arro-

gance when the Macedonian kings had their family statues made of chryselephantine work. See SCULPTURE.

Chrysippus, an eminent Stoic philosopher, was born about 280 B.C., at Soli in Cilicia. He came to Athens when still a youth, and devoted himself with ardour to philosophy. His principal master was Cleanthes, but he is said to have studied also under the academic teachers, Arcesilaus and Lacydes. He had the reputation of being the keenest disputant and best logician of his age, so much so that people used to say: 'If the gods make use of dialectic, it can only be that of Chrysippus.' Although he did not create a new system, and explained the physical universe like the rest of his school, in morals he modified the more extreme views of the earlier Stoics. Chrysippus seldom wrote less than 500 lines a day, and is said to have composed more than 700 works. Of these but a few fragments remain, which were edited by Petersen in 1827. See Zeller's great work on the history of Greek philosophy.

Chrysis ('golden-wasp'), a genus of hymenopterous insects, type of a family Chrysidæ, with about 400 species. Their systematic position is not far from that of the true wasps. The French call them *Guêpes dorées* ('gilded wasps'), and they sometimes receive the English names of Golden-tailed and Ruby-tailed Flies. They delight in sunshine, and may be seen poised in the air—the motion of their wings being so rapid as to render the body alone of the insect visible.

Chrysobalanææ, a sub-order of Rosaceæ (q.v.), presenting close affinities through Cæs-alpinæ to Leguminosæ. The 180 species are trees or shrubs, natives of tropical and sub-tropical America and Africa. The fruit of many is eatable, as the Cocoa Plum (q.v.) of the West Indies (Chrysobalanus). The kernels of some resemble sweet-almonds, notably those of *Acia dulcis*, and other species of Guiana. A useful oil is expressed from the seeds of *Prinsepia utilis*, a spiny Himalayan plant.

Chrysoberyl (Gr., 'golden beryl'), a gem almost as hard as sapphire, and the finer specimens of which are very beautiful, particularly those which exhibit an opalescent play of light. Lapidaries sometimes call it oriental or opalescent chrysolite. It is of a green colour, inclining to yellow, semi-transparent, or almost transparent, and has double refraction. It occurs crystallised in six-sided prisms; often in masses, or twin crystals. It is found occasionally in granite, but more frequently in gneiss and mica-schist; sometimes it occurs in sandstone or in alluvial soil derived from the disintegration of schistose rocks. Localities for its occurrence are the Ural Mountains, Ceylon, Pegu, Brazil, and Connecticut. It is composed of alumina, glucina, and small proportions of ferric oxide, titanin acid, and sesquioxide of chromium—the alumina being about 80 per cent. of the whole. The chrysoberyl of the ancients was a different mineral, probably the Chrysoprase (q.v.) of the moderns.

Chrysocolla, an ore of Copper (q.v.).

Chrysolite (Gr., 'golden-stone'), a mineral composed of silica, magnesia, and protoxide of iron; of a fine yellowish-green colour, with vitreous lustre; transparent, and having double refraction; in hardness, about equal to quartz; and with conchoidal fracture. It often crystallises in four-sided or six-sided prisms, variously modified. Very fine specimens are brought from Egypt and from some parts of the East, also from Brazil. Chrysolite is used by jewellers as an ornamental stone, but is not highly valued. *Olivine*, or com-

mon chrysolite, is an important rock-forming mineral. It is dark yellowish-green in colour, and occurs generally in somewhat rounded grains or corroded crystals in some igneous rocks, such as the basalts. Occasionally large granular masses, which may have a rectangular outline, are met with in lavas—some of them weighing as much as 30 lb.

Chrysolo'ras, MANUEL, the first to transplant Greek literature into Italy, was born at Constantinople in the middle of the 14th century A.D. About the year 1391 he was sent by the Byzantine emperor, John Palæologus, to England and Italy to entreat assistance against the Turks, and in 1397 he left his native land and went to Florence, where, as teacher of Greek literature, he was highly esteemed and admired. Leonardo Bruno, Poggius, Philépphus, Guarinus of Verona, and other eminent scholars were among his pupils. He was afterwards employed by Pope Gregory XII. in an attempt to promote a union of the Greek with the Roman Church, and in 1413 went with John XXIII. to the Council of Constance, where he died 1415. His chief work was *Erotemata*, a Greek grammar (Venice, 1484).—Manuel Chrysoloras must be distinguished from his nephew, JOHN CHRYSOLORAS, who also went to Italy and gave instruction in Greek.

Chrysomela. See COLORADO BEETLE.

Chrysophyllum. See STAR APPLE.

Chrysoprase (Gr. *chrysos*, 'gold,' *prason*, 'a leek') is merely a variety of chalcedony, but is valued far above common chalcedony as an ornamental stone; its reputation as a precious stone is much higher on the Continent than in this country. It is of a fine leek or apple-green colour in choice specimens, but inferior ones exhibit other shades of green, and it is sometimes spotted with yellowish-brown. It is often set in a circlet of diamonds or pearls. Unfortunately, it is apt to lose its colour through time, particularly if kept in a warm place.

Chrysops. See CLEG.

Chrysostom, ST JOHN (Gr. *Chrysostómos*, 'golden-mouthed'; so named from the splendour of his eloquence), was born at Antioch about 347 A.D. His mother, Anthusa, was a pious woman, wholly devoted to her son, who grew up under her loving instructions into an earnest, gentle, and serious youth, passing through, as Neander significantly observes, none of those wild, dark struggles with sinful passions which left an ineffaceable impress on the soul of Augustine, and gave a sombre colouring to his whole theology. He studied oratory under the famous heathen rhetorician, Libanius, and began the career of an advocate; but, soon dissatisfied with this, he placed himself for three years under the instruction of Bishop Meletius, by whom in his twenty-third year he was baptised and ordained an *anagnostis* or 'Reader.' After six years spent as a monk in the mountains near Antioch, an illness forced him to return in 380 to that city, where he was ordained deacon by Bishop Meletius in 381, and presbyter by Bishop Flavianus in 386. The eloquence, earnestness, and practical tone of his preaching excited the attention of Jews, heathens, and heretics, and secured for him the reputation of the greatest orator of the ancient church. In 398 the Emperor Arcadius elevated him to the archiepiscopate of Constantinople. Chrysostom immediately began to restrict the expenditure in which his predecessors had indulged, and bestowed so large a portion of his revenues on hospitals and other charities that he gained the surname of 'John the Almoner.' He also endeavoured to reform the lives of the clergy, and

sent monks as missionaries into Scythia, Persia, Palestine, and other lands. His faithful discharge of his duties, especially in reproof of vices, excited the enmity of the patriarch Theophilus and of the Empress Eudoxia, who succeeded in deposing and banishing him from the capital in 403. He was soon recalled, to be banished again in 404. After a short stay at Nicæa, he was removed to the little town of Cucusus, in the desert parts of the Taurus Mountains. Even here his zeal was not abated. He laboured for the conversion of the Persians and Goths in the neighbourhood, and wrote the seventeen letters or rather moral essays to Olympias, to whom he also addressed a treatise on the proposition—'None can hurt the man who will not hurt himself.' The intercession of Innocent I. of Rome and the Emperor Honorius only moved Arcadius to order that he should be more remotely banished to Pityus on the Euxine, at the very verge of the Eastern Roman empire. Accordingly, the old man was made to travel on foot, and with his bare head exposed to a burning sun. This cruelty proved fatal. Chrysostom died on the way at Comana, in Pontus, September 14, 407 A.D., blessing God with his dying lips. A sect sprang up after his death called *Johannists*, who refused to acknowledge his successors; nor did they return to the general communion till 438, when the Archbishop Proclus prevailed on the Emperor Theodosius II. to bring back the body of the saint to Constantinople, where it was solemnly interred, the emperor himself publicly imploring the pardon of Heaven for the crime of his parents, Arcadius and Eudoxia. The Greek Church celebrates the festival of Chrysostom on the 13th of November; the Roman, on the 27th of January. St Chrysostom's works are very numerous, and consist of *Homilies* on parts of Scripture and points of doctrine; *Commentaries* on the whole Bible, part of which have perished; *Epistles* addressed to various people; *Treatises* on different subjects, such as Providence, the Priesthood, and the like; and *Liturgies*. Of these the most valuable, as well as the most studied, are the *Homilies*, which are rightly held to be superior to everything of the kind in ancient Christian literature. Thomas Aquinas said he would not give in exchange those on St Matthew for the whole city of Paris. Here his exegesis is sound, practical, and very 'English,' in Cardinal Newman's phrase. In general he rejects the allegorical system of interpretation, and adheres to the grammatical, basing his doctrines and sentiments on a rational apprehension of the letter of Scripture. He is, however, far from being a bibliolater. He recognised the presence of a human element in the Bible as well as a divine; and, instead of attempting by forced and artificial hypotheses to reconcile what he thought irreconcilable in Scripture statements, he frankly admitted the existence of contradictions, and shaped his theory of inspiration accordingly. But his greatest excellence lay in that power, springing from the fervour and holiness of his heart, by which the consciences of the proud, the worldly, and the profligate were awakened, and all were made to feel the reality of the gospel message. The historian Sozomen says of him, that he was 'mighty to speak and to convince, surpassing all the orators of his time.' The surname Chrysostom was first applied some time after his death, and is first found in Isidore of Seville, who died in 636.

The best edition of St Chrysostom's works is that of Bernard de Montfaucon in 13 vols. folio (Paris, 1718-38; reprinted by the Abbé Migne, Paris, 1863), which was largely based on the splendid edition of Sir Henry Savile, printed at a cost of £8000 (Eton, 8 vols. 1613), 'the first work of learning on a great scale,' says Hallam, 'published in England.' Some

of the *Homilies* are translated in the Oxford *Library of the Fathers*.

See the older church historians; and cf. the moderns, especially Neander, both in his *History* and in his special book on St Chrysostom, translated by J. C. Stapleton (1838). See also Thierry, *Chrysostom et l'Impératrice Eudoxie* (2d ed. Paris, 1874); Newman's *Historical Sketches* (1873); W. R. W. Stephens, *St Chrysostom: His Life and Times* (1872); and R. W. Busk, *Life and Times of Chrysostom* (1885).

Chrysotype, a photographic process, the result being produced mainly by a solution of chloride of gold. See **PHOTOGRAPHY**.

Chub (*Leuciscus cephalus*), a fish of the carp family Cyprinidae, of the same genus with the roach, dace, bleak, minnow, &c. The colour is bluish-black on the upper parts, passing into white on the belly; the cheeks and gill-covers rich golden yellow. The weight rarely exceeds 5 lb. It is plentiful in the rivers of England, and occurs in some of those of the south-west of Scotland, in Europe, and in Asia Minor. It spawns in April

Chub.

and May, and comes into condition again by the end of June or early in July. It prefers rapid water and a clear bottom, and often hides in holes. Its diet is very mixed. It is not much esteemed for the table. The scales have been used for making artificial pearl. See **PEARLS**. The common American chub is the *Leucosomus rhotheus*.

Chubb, CHARLES, locksmith, was patentee of several important improvements in 'detector' locks, originally patented by his brother, Jeremiah Chubb of Portsea, in 1818. He was in the hardware business at Winchester and Portsea previous to his settlement in London, where he died, 16th May 1845. Under his son and successor, John Chubb (1816-72), further patents were taken out and improvements made in locks and safes, and the business was greatly developed.

Chubb, THOMAS, an English deist, who wrote on religious questions during the first half of the 18th century, was born at East-Harnham near Salisbury in 1670. His father, who had been a maltster, died early, consequently his children were poorly educated and early set to work. Thomas was first apprenticed to a glover in Salisbury, but his eyesight becoming weak, he became an assistant to a tallow-chandler, in which employment he died in 1746. He had already contrived to pick up considerable learning, when a perusal of the 'historical preface' to Whiston's *Primitive Christianity Revived* impelled him to write his own tract, *The Supremacy of the Father Asserted*, which Whiston helped him to publish in 1715. Encouraged by the patronage of Sir Joseph Jekyll and others, he continued to write, and a quarto volume of his tracts, published in 1730, made his name known to everybody. His opinions drifted nearer and nearer to deism, yet he went regularly to his parish church and regarded the mission, if not the person, of Christ as divine. Unfortunately his learning was far inferior to his natural ability, and his teaching lacks distinctness and consistency. His principal works are—*A Discourse concerning Reason . . . a sufficient Guide in matters of Religion* (1731); *The True Gospel of Jesus Christ Asserted* (1738), followed by a defence against the critics; *An Enquiry into the Ground and Foundation of Religion, where-*

in it is shown that Religion is founded on Nature (1738); and a *Discourse on Miracles* (1741). The best statement of his views is contained in his *Posthumous Works* (2 vols. 1748).

Chubut, or CHUPAT, a colony in Patagonia, so named from a river which drains a large part of its area. The entrance to the river, about 600 miles S. of the river Plate, is bad, but the bar can be crossed by vessels of from 7 to 12 feet draught. Its principal interest lies in its Welsh settlement, which has remained almost wholly Welsh-speaking. The first settlers, 151, arrived in July 1865. Epochs in its history have been the abandonment of the colony in 1867; the subsequent return from New Bay; a twenty months' nearly complete isolation from the outer world, terminated in 1871. The population, after dwindling to 120, rose to 690 in 1876, and 1286 in 1883. The principal town, Trerawson, or Rawsonville, about 5 miles from the sea, is named after Dr Rawson, an Argentine statesman. Frosts seldom last through the day, fogs are infrequent, English grain and roots are produced, and salt of good quality is found. There are a president and council. A concession has been granted for a railway of about 40 miles to New Bay.

Chuck-Will's-widow. See WHIP-POOR-WILL.

Chudleigh, CAPE, is on the north coast of Labrador, at the entrance of Hudson Strait, 60° 12' N. lat., 65° 25' W. long.

Chumbul', a river of Central India, rising in the Vindhyan Mountains, at a height of 2019 feet above the sea, and entering the Jumna, after a generally north-east course of 650 miles.

Chunam, the Indian name for a very fine kind of quicklime made from calcined shells or from very pure limestone, and used for chewing with Betel (q.v.), and for plaster. When chunam is to be used for plaster, it is mixed with fine river-sand, and thoroughly beaten up with water. A little *jaggery* (coarse sugar) is also added.

Chunar', a fortified town of India, on the right bank of the Ganges, 26 miles SW. of Benares. The fortress contains Warren Hastings' house, now used as infantry barracks, and his staff-quarters. Pop. (1881) 9148.

Chupra (*Chapra*'), a town of Bengal, on the Gogra, a mile above its confluence with the Ganges. Pop. (1881) 51,670.

Chuquisaca, or SUCRE, capital of Bolivia, is situated on a mountain-closed tableland, 8825 feet above the sea, on a small tributary of the Pilcomayo. It is the seat of an archbishop, and though its houses are mostly of one story, is well built, and has a magnificent cathedral, a small university, a Latin school, and a hospital. Owing to its mild climate, many of the richer miners of Potosi winter here. The 17,000 inhabitants are mostly a mixture of Spaniards and Quichua Indians. Chuquisaca was founded in 1539 on the site of an ancient Peruvian town of the same name, and was for a time called *Ciudad de la Plata*, from the rich silver-mines in the neighbouring mountains; but the Peruvian name signifying 'bridge of gold' was soon restored. The second name, Sucre, is derived from the general who in December 1824 fought and won the last great battle for colonial independence at Ayacucho.—The southern territory of the same name embraces a large portion of the Gran Chaco, which extends to the Brazilian frontier. The eastern portion of it is occupied by wild Indian tribes, and is low-lying and unwholesome; the climate of the west, among the foothills of the Eastern Cordilleras, is healthy and pleasant. Area, 71,744 sq. m.; pop. (1861, the last census) 273,668,

not inclusive of some 50,000 Indians in the eastern plains.

Chuquito, a town of Peru, once capital of a province, on the west shore of Lake Titicaca. Pop. 5000.

Chur. See COIRE.

Church, the whole body of Christians; the Christian place of worship; the clergy; or a sect or denomination of Christians. It is derived from the Greek *kyriakon*, 'belonging to the Lord,' and that from *kyrios*, 'lord'; the Anglo-Saxon form is *circe*, the Scottish *kirk*, the German *kirche*. The *kyriakon*, the original name of the place of assembly, meant accordingly 'the Lord's house.' The Christian Church, like every other society, must have a certain constitution and rules according to which its affairs are administered. It is disputed, however, among Christians, how far this constitution has been defined, or these rules prescribed by divine authority, and how far they have been left to the discretion of men. The form of church government depends primarily on the idea entertained of the constitution of the church. Episcopalians and Presbyterians agree that many congregations are to be united under a common government; but this, according to Episcopalians, should be more or less absolutely in the hands of bishops, who are superior to the mere pastors of congregations; while according to Presbyterians it should be carried on by ministers and elders of these congregations meeting for this purpose on a footing of equality. Congregationalists, or Independents, place all church government in the hands of the members of each congregation and the office-bearers whom it has elected. This theory of church government is maintained by many Baptists and others who, for various reasons, assume different denominations. See BISHOP, PRESBYTERIANISM, INDEPENDENTS, METHODISTS.

The present article is mainly devoted to church architecture. A general sketch of the history of the Christian Church will be found in this work under the head of CHURCH HISTORY, while the various sections forming the great Christian communions are treated in separate articles—the Church of England at ENGLAND, as is that of Scotland at SCOTLAND; again the Church of Rome will be found at ROMAN CATHOLIC CHURCH, and the Eastern Church at GREK CHURCH. Here we may merely note the self-explanatory names of the following active organisations within the bosom of the Anglican Church: the Church Association (founded 1865 for the maintenance of Reformation principles); Church Congresses (annual since 1860); Church Building Society (1818); Church Defence Institution (1886, to counteract the agitation for disestablishment); Church Missionary Society (founded 1799; see MISSIONS); Church Pastoral Aid Society (1836, to maintain curates and lay agents in densely populated districts); the English Church Union (1859, to uphold Anglo-Catholic principles).

Under BASILICA some account is given of the mode in which the primitive form of the Christian church or place of assembly originated, and whence it derived its characteristic features. In course of time the numbers of the clergy increased, and a complete hierarchy, with a fixed liturgical service, became established. The simple apse was now no longer sufficient, and the presbytery or place for the clergy was enlarged. This was effected in various ways, sometimes by the erection of a low inclosure or choir extending from the presbytery or raised part in front of the apse, into the nave. This 'bema' or choir served for the accommodation of the clergy and singers, and to it were attached on either side two pulpits or *ambones*,

from which the Gospels and Epistles were read to the worshippers assembled round the three open sides. Such an arrangement may still be seen in the ancient basilica of San Clemente in Rome.

In other instances the apse is lengthened eastwards so as to provide additional space. An example of this plan occurs at S. Apollinare in Classe, near Ravenna. In the Basilican churches the nave remained as at first, a long simple hall, with side aisles—in which the congregation assembled, the men on one side, and the women on the other. Meanwhile in the East the use of the dome had caused the introduction of a variety of plans, and in particular the form of the Greek cross, which was conveniently roofed by a large central dome and four subsidiary domes over the four arms of the cross. This plan suggested the transept or

Church :

C, Choir; N, Nave;
N T, North Transept;
S T, South Transept.

portion with high roof at right angles to the nave; and it is easy to see how the wide space in the Basilican churches between the nave and apse, in which stood the altar, might also be enlarged so as to form a transept. The above is what actually happened in the south of France. The Venetian merchants introduced the above Greek domed design at Périgueux, where they had reproduced in the 11th century a copy of St Mark's of Venice; and we find in the churches of that district a transept introduced from an early period, having several apses to the east, and side aisles like the nave.

It was especially necessary in the churches of the monasteries that there should be ample accommodation for the monks in the portion of the church set apart for them. This probably led to the lengthening of the choir, but in the earlier Cistercian churches, although the transept is introduced, there is no projection to the east except the central and side apses. But when the plan of the 'cross' church, however it may have been invented, had been developed, the idea speedily claimed attention, and its symbolical significance recommended its adoption. It is remarkable, however, that during the growth and development of the early Gothic style in the reign of Philip Augustus, when most of the cathedrals and churches of northern France were rebuilt, they were almost all constructed without transepts, the object apparently being to concentrate the attention on the one important point, the high altar. It was in the monastic churches that the transept was chiefly developed.

Along with this, another feature, which had first been introduced in the south, was worked out and perfected by the northern architects—viz. the carrying of the aisle round the apse, so as to convert the latter from being a simple half-cylinder, roofed with a semi-dome, into a circular or octagonal east end, supported on a screen of pillars, behind which was the surrounding aisle, with its radiating chapels, while the upper part of the apse was carried up the full height of the choir, which it terminated with a brilliant east end. Mr Fergusson supposes that this 'chevet,' or splendid eastern termination of French Gothic churches, was the result of the absorption of a circular edifice into the church. There is no doubt that the church owes several of its features to this system of absorption. Originally the group of ecclesiastical buildings consisted of the church or basilica, at the west end of which was an atrium or open court, having a circular or octagonal baptistery opening from it opposite the

door to the church. In Germany the atrium was roofed in and became part of the church, while the western baptistery was also absorbed into the one chief edifice, and became the western apse so common in that country. But it had also been customary to build occasional churches of a circular form in imitation of the church of the Holy Sepulchre at Jerusalem. In Germany and elsewhere a choir was added to these for the use of the clergy, but in France the circular church was retained by the clergy as the choir, and a nave was constructed in connection with it for the people. The fine effect of the circular termination was thus seen, and had only to be seen to be immediately adopted. Besides the chapels radiating from the 'chevet,' numerous others were gradually introduced, extending beyond the aisles; the height of the main structure was increased, and great windows were inserted in the clerestory, till the interior presented a glowing vision of rich colour and endless variety of perspective.

Such was the growth of the Christian church during the middle ages, and such is the general form it still retains in Roman Catholic countries, notwithstanding the great changes of style through which it has passed from the 13th to the 19th century. Since the Reformation a new form of church has been introduced. The ancient traditions were no longer held sacred by Protestants, and a style of building adapted to the new mode of service was called for. Hence arose the arrangements of the numerous churches designed by Sir C. Wren, Gibbs, and others during the 17th and 18th centuries. These consist of a great hall with a gallery running along the two sides and west end, with a large window or apse at the east end. During the present century the plan of the medieval church has frequently been again resorted to, both in England and the United States; but among Presbyterians, Independents, and many others, the modern plan of a hall designed with galleries so as to contain a numerous congregation, having the pulpit placed in the most prominent position, is still the most generally used.

The following table shows the comparative size of some of the great churches of the world, giving in feet their total length, breadth at transept, and height of spire or tower or dome :

	Length.	Transept.	Spire.
St Peter's, Rome.....	700	500	440
Cathedral of Florence.....	530	323	380
Milan Cathedral.....	600	284	400
Cologne Cathedral.....	445	282	50
Strasbourg Cathedral.....	354	..	474
Antwerp Cathedral.....	600	180	460
Amiens Cathedral.....	442	104	225
Notre Dame, Paris.....	400	150	204
St Paul's, London.....	510	282	404

Glasgow Cathedral.....	319	..	225
St Patrick's Cathedral, New York.....	332	174	328

Churches vary of course in accordance with their importance and size. The largest are the metropolitan and cathedral churches, then the conventual, the collegiate, and the parish churches; but although they vary in magnitude and richness, they are all constructed on the same principles, and follow one idea.

The annexed ground-plan of Durham Cathedral shows the various parts of one of the most perfect medieval structures in England, with the names attached to the different portions, which will be described under their respective headings. See AISLE, APSE, BASILICA, CLERESTORY, TRIFORIUM, &c. Plans, sections, or other illustrations of other important churches will be found at BYZANTINE ARCHITECTURE, GOTHIC ARCHITECTURE, LOM-

BARD ARCHITECTURE, RENAISSANCE, RHENISH ARCHITECTURE, &c., where much additional information on the developments of church building falls to be given. For the historical succession of the

Bishop Andrewes are only less valuable. His Bacon, Spenser, St Anselm, Dante, and some of his miscellaneous essays, were reprinted in a uniform edition in 5 volumes in 1888.

styles, see ARCHITECTURE; see also AMIENS, ANTWERP, BURGOS, CANTERBURY, &c.

Church, RICHARD WILLIAM, Dean of St Paul's since 1871, was born in 1815. He spent a great part of his youth in Italy and elsewhere on the Continent, took a first-class at Oxford in 1836, and soon after was elected to a fellowship at Oriel. From 1853 he held the rectory of Whatley, near Frome. In 1854 he published *Essays and Reviews*, and thereby took rank almost at once as one of the most graceful and scholarly writers of the day. His university sermons (1876-78) in a volume entitled *Human Life and its Conditions* (1878), the series of St Paul's and Oxford sermons in *The Gifts of Civilisation* (1880), and the five St Paul's sermons forming *The Discipline of the Christian Character* (1885), are profound contributions to religious thought. Other works are his *Life of St Anselm* (1871), an amplification of two essays in his first volume; *The Beginning of the Middle Ages* (1877), an introduction to the series of 'Epochs of Modern History'; *Dante: an Essay*, with a translation of the *De Monarchia* by his only son, F. J. Church, a young man of rare promise, who died in 1887; *Spenser* (1879), and *Bacon* (1879), two of the best books in the series of 'English Men of Letters.' His occasional essays or lectures on such subjects as Montaigne, Brittany, Cassiodorus, the sacred poetry of early religions, the *Pensées* of Pascal and

Church, STATES OF THE, or PAPAL STATES (Ital. *Stati della Chiesa*, or *Stati Pontifici*), a territory or group of states in Central Italy, formerly united under one sovereignty, with the pope for its head. Its extent varied at different times, but in 1859, the last year of its entirety, the area was 15,774 sq. m., the pop. over 3,000,000. It stretched irregularly from the Po in the north to Naples in the south, and was divided for administrative purposes into twenty districts, including the Comarca of Rome; six legations, among them those of Bologna and Ravenna; and thirteen delegations, including Ancona and Perugia. More general divisions were the *Romagna*, *Umbria*, and the *Marche of Ancona*. The war of 1859 left the pope only the Comarca of Rome, the legation of Velletri, and the delegations of Civita Vecchia, Frosinone, and Viterbo, 4493 sq. m. in extent, with a pop. of about 700,000. The temporal power of the popes originated in a gift of the exarchate of Ravenna by Pepin to Pope Stephen II., and it reached its greatest extent under Innocent III. (1198-1216). The share of the Papacy in the secular affairs of Italy was at no time other than prejudicial to the highest spiritual interests of the Church, yet when the withdrawal of the French garrison of Rome in 1870 led to the final downfall of his temporal power, Pius IX., as 'the prisoner of the Vatican,' continued to hurl vain anathemas at the head of the king of Italy. See POPE, ITALY.

Church-ale, a kind of church festival in old England at which ale was drunk liberally. The name is obviously compounded like *bridal* = *bride-ale*, *scot-ale*, *clerk-ale*, *bid-ale*, &c. The church-ales were usually held upon Whitsuntide, and two persons were chosen beforehand to preside over the feast, and divide out the victuals and drink voluntarily contributed by the parishioners. Sometimes the drink which had been brewed from malt given by the parishioners was sold about Whitsunday at the church for the support of orphans and poor, the repair of the church, and similar objects. The practice of holding church-ales with the corresponding games was denounced by the Puritans, and is not overlooked in Stubbs' *Anatomie of Abuses*.

Church Discipline (*Disciplina ecclesiastica*), the practice of the Christian Church in dealing with such of its office-bearers and members as have by public scandal caused hindrance to its common spiritual life. Its Scripture authority, resting on such passages as Matt. xvi. 19; xviii. 15 (*et seq.*), is further enforced in Paul's epistles and in the gospel and epistles of John. Under the Decian persecution there was so much apostasy that special rules became fixed for the restoration of the *Lapsed* (q.v.), which remained in force till the 5th century. But the great strictness with which Penance (q.v.) was enforced led to the opposite extreme; it became customary for penitents to be restored

simply on their producing letters of recommendation (*libelli pacis*) from persons who had confessed Christ. The Montanists, however, maintained that those who had been once excommunicated should pass their whole life in the *status penitentie*, and the Novatians denied that the Church possessed the right to assure the *Lapsi* of the forgiveness of sins, which only God could grant. The Donatists (q.v.) could not arrest the gradual secularisation of discipline. By the 6th century penances began to be commuted for certain fixed taxes. In the Western Church, after public penances had become rare, other punishments took their place, partly derived from the exercises of earlier asceticism, partly from the usages of Frankish law. The episcopal *Missi* of Charles the Great combined the functions of a civil and ecclesiastical court, and allowed church punishments to be compounded for money. From the time of Gregory the Great the doctrine of Purgatory (q.v.) had been a dogma of the Church; and Peter Lombard and other scholastics built on it the theory of Indulgences (q.v.), which was confirmed by Clement VI. in 1343. The extreme punishments in the middle ages were the Greater Excommunication (q.v.) for the individual, and Interdict (q.v.) for the community. The churches of the Reformation held that 'the power of the keys' belonged to the whole Church, by which it was to be intrusted to the regularly called servants of the Word. They rejected Auricular Confession (q.v.) and the whole system of Satisfaction and Indulgences; restricting the sphere of their church discipline to matters of social morality, and its enforcement simply to spiritual admonition and partial or complete exclusion from the sacraments and offices of the Church. The Lutheran Church rejected the Greater Excommunication as a merely secular punishment with which the servants of the Church had nothing to do; but retained the Lesser, simply as a means of moral training. Though Luther and Melancthon adhered firmly to the participation of the whole congregation in the imposition of excommunication, yet, in consequence of the development of the consistorial system, it passed into the hands of the consistories in the different states. In the 17th and 18th centuries it fell gradually into disuse. The Reformed Church laid greater stress on congregational discipline. Zwingli assigned it to the civil magistrate of the Christian state; Calvin, on the other hand, referred it to the Presbytery (q.v.). In Presbyterian churches it is exercised by the kirk-session—an appeal lying to the presbytery, and from that to the synod and general assembly. The church discipline provided for by the Canons of the Church of England has almost entirely fallen into disuse.

Church History. The history of the Christian Church includes its external history, which treats of the extension of the Church, and its relation to the state; and internal history, which is concerned with the Church's inner life, doctrine, worship, and constitution. With respect to time, the Church's history is usually divided into three periods—*Ancient*, *Medieval*, and *Modern*. Its Medieval History may be dated from its establishment in union with the new empire founded by Charles the Great in 800. Modern Church History begins with the Reformation (in the view of Roman Catholic historians, with the Humanistic movement, or the discovery of America). Each of these periods may be divided into two: Ancient Church History, at the complete victory of Christianity over Greek heathenism under Constantine the Great; Medieval, at the culmination of the papal power under Innocent III.; and Modern, at the close of the Thirty Years' War by the Treaty of Westphalia.

The first of these periods extends from Christ to Constantine. The beginning of the Christian Church dates from the departure of Jesus Christ from the earth and the Pentecostal effusion of the Holy Spirit (about 33 A.D.), the time when the first confessors of Christ exceeded the limits of a private society, and began to form a public community. Its nucleus was the first Jewish Christian community at Jerusalem under the 'pillar-apostles' James, Cephas, and John. The spiritual conception of the Messiah which the disciples had received from the personal influence of Jesus was sealed on their minds by their faith in his resurrection; and their comprehension of his gospel is seen in the wide aims of their first missions, in their progressive deliverance from legalism, and in the belief that faith is the essential element of salvation. As members were quickly added to the Church, especially from the Jews of the Dispersion (called Hellenists, because they spoke Greek), a beginning of its organisation was made in the appointment of seven deacons, including the Hellenist Stephen, the protomartyr of the Church. The elements of the primitive faith were unified and systematised by the Apostle Paul, the aim of whose life was the conversion of the whole world to Christ. He succeeded in emancipating the Gentile Christian world from the ceremonial law, and in his three great missionary journeys (about 40–55 A.D.) began the evangelisation of Europe. The destruction of Jerusalem (70 A.D.) completed the deliverance of Christianity from Judaism, and gave the Church the consciousness of a world-wide mission. The Judaising Christians were thenceforth an insignificant sect.

The Roman empire maintained the pre-Christian view that there could be no worship of God apart from the corporate life of the state, and, when the early Christian Church refused to take part in the state worship, it became a *religio illicita*, and was proscribed and persecuted as dangerous to society. To the distinguished and learned Christianity was a gloomy infatuation, to the populace the Christians' contempt for the gods seemed the cause of every public calamity. The tyrannical caprice of Nero charged them with the burning of Rome (64 A.D.), and persecuted them with revolting cruelty. Under Domitian Christianity was punished as a form of high treason. The first regular decree for legal procedure against the Christians was issued by Trajan. Under the more tolerant rule of the emperors from Hadrian to Marcus Aurelius (117–161), the Christian congregations were organised as *Collegia tentorii* ('poor men's guilds'), or *Collegia funeraticia* ('funeral societies'), and as such enjoyed a sort of legalised existence. The vast cities of their dead in the catacombs of this period nowhere preserve memorials of martyrdom or persecution. The Christians had to suffer many a local persecution, but, apart from the temporary and thoughtless cruelties of Nero and Domitian—who, according to Tertullian, was 'a piece of Nero for cruelty'—they had the toleration, and sometimes the protection, of the emperors. Ranke ascribes such action especially to Antoninus Pius—'the best-intentioned and most peaceable among them, and perhaps not without sympathy for Christianity'—whose reign he regards as the culmination of the Roman empire. A consequence of this tolerant bearing of the imperial power was the peaceful behaviour of the Christians, who in general rejected the principles of Montanus, which aimed at the subversion of the state. This condition of affairs came to an end under Marcus Aurelius, who, no longer able to resist the popular outcry, suffered a persecution to take place in several provinces.

About the middle of the 2d century the Christian congregations in the Roman empire were consoli-

dating themselves into a confederacy, which called itself the 'Great' or 'Catholic' (i.e. universal) Church. By the middle of the 3d century the confederation was accomplished. The Church was now organised with a hierarchical constitution and an elaborately regulated worship, while the New Testament canon was regarded as equally authoritative with the Old. From 250 the emperors whose political aims were most akin to the traditional policy of Rome struggled for life and death with the growing power. Of the times before Decius Origen testifies (*Contra Celsum*, iii. 8) 'few and very easy to count are those who have died on account of the Christian religion;' and Lactantius says (*De Morte Persecutorum*, iii. 4), 'after the acts of the tyrant (Domitian) had been rescinded, the Church was not only restored to her pristine state, but shone forth much more brightly; and, times following when many good emperors held the helm of government, she suffered no attacks from enemies. . . . But thereafter the long peace was broken. For after many years the accursed beast (*cæcra animal*) Decius arose to vex the Church.' Under Decius began the first universal and systematic persecution of Christianity as a part of the military and religious policy of the state. The sufferings of the Christians continued under Gallus and Valerian till 260, when Gallienus declared Christianity a *religio licita*. For forty years the Church had peace, and grew mightily on every side. Diocletian by four edicts of progressive severity, from February 303 to March 304, when he decreed torture for all Christians, put forth a desperate effort to annihilate Christianity in the whole empire. At his abdication (May 305) the horrors of the persecution ended, except in the East, where they were continued without mercy by Maximin Daza. The victory of Constantine in 313 delivered Christendom from this its last and most relentless persecutor.

Constantine saw in the unity of the Church a new foundation for the unity of the empire, and placed Christianity on an equality with Paganism: under his sons it became predominant. The reaction under Julian ended with his death. It was the struggle with Gnosticism that had first led the Church to the remarkable development of its dogmatic system, which gives its characteristic stamp to the history of the second period of the ancient church. The simple baptismal confession had become transformed into a rule of faith giving fixity to the ecclesiastical tradition. Justin, Irenæus, Tertullian, and Hippolytus had been among its first exponents. While in the scriptures of the New Testament canon the Church possessed an abiding witness to the 'simplicity that is in Christ,' the rule of faith in the course of the 3d century had been built up in the forms of the Greek philosophy of Clement and Origen. The first church synods had been held in Asia Minor in connection with the Montanist controversy about 170; and by the 3d century such assemblies were common in various provinces of the empire. The institution of œcumenical councils, in which only bishops were entitled to vote, originated with Constantine. The controversy with respect to the Easter festival had disturbed the Church for a century and a half. The universal practice in Asia was to observe the exact day of the month (the 14th Nisan), while the usage of Alexandria and Palestine and the West was to celebrate the Passion always on a Friday, and the Resurrection on a Sunday. This controversy was finally laid at rest by the Ecumenical Council of Nicæa in 325. Trinitarianism gained its first victory over Arianism at Nicæa by the combined influence of Athanasius and Constantine, and completed its triumph at the second Ecumenical Council (at Constantinople) in 381.

After this the Church was distracted with controversies about the views of Origen (394-438), the Apollinarian controversy (362-381), the disputes between the schools of Antioch and Alexandria (381-428), the Nestorian controversy (428-444), the Monophysite controversy (444-553), the Monothelete controversy (633-680), and the Iconoclastic controversy (726-842). These discussions originated in the Eastern Church, while in the West the theological interest centred on the great conflict between Augustinianism and Pelagianism (412-529). The tyrannical interference of the Eastern emperors in the controversies of the Church, their supremacy in the ecclesiastical councils, and their penal enforcement of doctrinal decrees, led to infinite confusion in the relations between church and state, and prepared the way for the ambitious policy of the popes, and for the final breach between the churches of the East and West.

While these age-long controversies kept the relations of church and state continually strained, Paganism was steadily suppressed. Orthodox Christianity in union with the state soothed the declining years of the ancient empire; but could not prevent the conquest of Rome by Alaric the Goth. Its advance in Persia was checked by political persecution before the advent of Islam, which subsequently overwhelmed the Christianity of the East. In the West, however, Christianity rose with renewed vigour from the ruins of the old empire, by the conversion of the Teutonic and Slavonic nations. The Teutonic conquerors of Gaul and Italy were Christians before their invasion of those countries. The Anglo-Saxon conquerors of England were heathens. A century and a half after their settlement Christian missionaries gained a footing in the south and north, and within a century from the landing of Augustine the English kingdoms had embraced Christianity. In the general declension of political faith under the decaying Roman empire, the social power once held by the officials of Rome had gradually passed into the hands of the Christian bishops. In the lawlessness and disorder of the barbarian invasions, these representatives of the claims of moral order and human brotherhood were the trusted mediators between the conquerors and the conquered, and exercised a constant influence during peace and war. But this great authority over the new nations brought along with it much injury to religion. Discipline declined as the power and wealth of the clergy increased.

The third period of the Church's history extends from Charles the Great to Innocent III. 'At the commencement of the 8th century,' says Ranke, 'on the one side Mohammedanism threatened to over-spread Italy and Gaul, and on the other the ancient idolatry of Saxony and Friesland once more forced its way across the Rhine. In this peril of Christian institutions, a youthful prince of Teutonic race, Charles Martel, arose as their champion.' By his great victory of Tours (732) a final check was given to the advance of the Saracens in the West, and Christendom and civilisation were rescued from the grasp of Islam. The subjugation of the Saxons by Charles the Great was the toilsome work of thirty-two years (772-804), and their Christianisation was secured by the castles, towns, mission-stations, and monasteries which the conqueror planted in their country. Under the Carolingian kings of the Franks from the middle of the 8th century, the temporal dominion of the Papacy was founded. The legend of the 'Donation of Constantine,' bestowing imperial power and dignities upon the pope, together with the sovereignty over Rome and all Italy, and the countries of the West, was invented at Rome about 730, and embodied in the Pseudo-Isidorian decretals (about 850). It was contested by few in the middle ages, till Laurentius

Valla demonstrated its untenability. For centuries this clumsy forgery formed one of the supports of the Papacy in its struggle for universal supremacy. The connection between the churches of the East and West had been already loosened by the schism of 484-519 during the Monophysite controversy, and by the iconoclastic policy of the emperors from Leo to Theophiles (717-842). At length the progressive centralisation of the Western Church under the Roman see, to whose authority the 'oecumenical bishops' of Constantinople could not submit, and in the 11th century the transfer by the Bulgarians of their allegiance from Constantinople to Rome, led to a final rupture. The patriarch Photius already in 867 laid down the dogmatic basis of the Schism as consisting in the western deviations from the dogmas, customs, and constitutional forms of the ancient church, especially the addition of the 'filioque' clause to the creed of Nicaea and Constantinople, teaching that the Holy Spirit proceeds not only from the Father, but also from the Son. The severance was completed on the 16th July 1054, when the papal legates laid the anathema on the altar of St Sophia in Constantinople.

The growth of Monasticism, from the beginning a lay movement in pursuit of the old ideal of Christian perfection, which men felt that a worldly priesthood no longer represented, entered at first into competition with the clergy, but gradually became subservient to Catholic aims. In the East, where the contemplative life prevailed, the best function of the monasteries was as nurseries of the priesthood, while the monks of the West christianised Germany and Britain, cultivated wildernesses, preserved the classic treasures of antiquity, and were the diligent teachers of the common people. Above all the monastic orders, the Benedictines can claim the glory of conspicuous services to Christian missions and intellectual culture. 'In the 9th and 10th centuries,' says Gibbon, 'the reign of the gospel and of the Church was extended over Bulgaria, Hungary, Bohemia, Saxony, Denmark, Norway, Sweden, Poland, and Russia. . . . The admission of the barbarians into the pale of civil and ecclesiastical society delivered Europe from the depredations by sea and land of the Normans, Hungarians, and Russians. The establishment of law and order was promoted by the influence of the clergy; and the rudiments of art and science were introduced into the savage countries of the globe.' In the West, men held that the Holy Roman Empire, consolidated by Charles and Otto the Great, was the embodiment of the ideal state, and that God had two vicars on earth, the emperor in temporal things, and the pope in spiritual things. 'The analogy of the two,' says Bryce, 'made them appear parts of one great world-movement towards unity; the coincidence of their boundaries, which had begun before Constantine, lasted long enough after him to associate them indissolubly together, and make the names of Roman and Christian convertible. . . . The Holy Roman Church and the Holy Roman Empire are one and the same thing in two aspects; and Catholicism, the principle of the universal Christian society, is also Romanism; that is, rests upon Rome as the origin and type of its universality, manifesting itself in a mystic dualism which corresponds to the two natures of its Founder. As divine and eternal, its head is the pope, to whom souls have been intrusted; as human and temporal, the emperor, commissioned to rule men's bodies and acts.' In the first half of the middle ages the Church believed herself to be co-extensive with the Kingdom of God, the realisation of the noblest ethical ideal, and her servants conceived it their highest duty to labour to make the

whole field of human life subject to her supremacy. Not even the moral declension of the Papacy in the centuries succeeding Charles the Great, especially during the sixty years' so-called Pornocracy (904-963), could quench the ardour of the Church's faith in that ideal; and the cloister, purged and strengthened by successive reforms, saved the authority of the Church by uniting in Gregory VII. the monastic ideal of self-renunciation with the ecclesiastical ideal of the conquest of the world.

At the great Lateran Council under Pope Innocent III. in 1215, the Catholic Church was at the zenith of its power. Innocent was the sun, and from him the princes of Christendom held their light in fee. The Crusaders, though unable to hold Jerusalem, had enhanced the prestige of the Papacy; and Scholasticism placed its skill and learning at the service of the Church. The Waldenses and Albigenses were to be crushed relentlessly, and the Inquisition was now established for their permanent repression. No persecutions which the Church had ever suffered are to be compared for determined cruelty with those which in this period she inflicted on the heretics of southern France and of the Netherlands. Emperors and kings might contend with Rome for temporal authority; they were ready to decree the burning of heretics as much as she desired. But this unrestricted sway brought its own downfall. After the Papacy in the Avignon sojourn (1305-77) had become the tool of French policy, and after all the contrivances of pious fraud had been resorted to, during the Schism of 1378 to 1409, to fill the coffers of rival popes at Avignon and at Rome, the people began to lose faith in the holiness of the hierarchy, and the ever louder cry for 'reformation of the Church in its head and members' became irresistible. The Schism of thirty years, during which two popes claimed the same divine prerogative, was the most direct contradiction of the doctrine that had obtained in the Catholic Church since the time of Hildebrand, that the Papacy was the unifying centre of Christendom. The conviction gained ground that even its authority was subject to that of an oecumenical council. In the development of this idea a twofold tendency presented itself. One party, that of Gerson and D'Ailly, which prevailed at the councils of Pisa and Constance, regarded the council as representative only of the hierarchy, and, while recognising the Papacy as a divine institution, aimed at restricting the absolutism of the papal see by the co-rule of a spiritual aristocracy, consisting of the bishops and the doctors of the universities. The other, mainly composed of German theologians, made the first attempt within the medieval Church to undermine the Roman Catholic conception of the Church by a distinction between the *ecclesia universalis*—the spiritual community of all believers—and the *ecclesia Romana*, of which the pope was head. The second party regarded this *una catholica ecclesia* alone as infallible, and held that the council represented not only all classes of the hierarchy, but all classes of Christendom; and that church reform was a duty that fell to the secular power, not only the princes, but also the entire body of the laity. But all the resolutions of the three great reforming councils were made void by the pitiful issue of the Council of Basel in the Concordat of Vienna in 1448, when the fathers of the council recognised Nicholas V., and received the holy father's forgiveness. Thus ended the last attempt towards the reformation of the Church on its old foundations.

At length the teaching of the Lollards and Hussites, the failure of the councils, and the shameless traffic in indulgences; the impotent conclusion of Scholasticism that philosophy and religion might both be true, though contradic-

tory; the new art and learning of the Renaissance; the awakening of the spirit of nationality; and the widespread longing of the poor for redress from the exactions of priests and nobles—had prepared men's minds for that great movement in the 16th century, which issued in the Protestant churches and in the division of the whole of western Christendom into two hostile camps down to the present day. Luther, Zwingli, Melancthon, and Calvin were its greatest leaders. The Reformation called forth a thousand changes in human existence. As it passed from country to country in all northern Europe, it broke the clerical yoke, abolished celibacy, confiscated the property of the Church, founded secular schools for the people, stripped the clergy of their privileges; and the philanthropic duties and the tasks of civilisation, which for centuries had been incumbent on the servants of the Church, it gradually transferred to the state and the community. Where it triumphed, and even where it was successfully resisted, there was no sphere of life in which its influence was not felt. The communistic movement of the Anabaptists, which had been developed in the midst of the religious perplexities of Germany, was crushed in the ruins of Münster in 1535, and with the death of 'this prodigal child of the Reformation' passed away the premature political socialism of the Reformation period. The aims of the Papacy, all centred on its political interests, were wholly irreconcilable with the Reformers' doctrine of the priesthood of all believers and the sole authority of Scripture in matters of faith. The political and humanistic period of the Papacy was succeeded by a régime of passionate zeal, under which every nerve was strained to win back the territories which had shaken off the Roman yoke. The resolutions of the Council of Trent (1545-63), subscribed by 255 prelates, separated for ever the Protestant and Catholic churches, and obtained in the latter the authority of a symbolical book.

The Counter-Reformation, led everywhere by the Jesuits, and favoured in Germany by the Peace of Augsburg (1555), went on with great success till the middle of the 17th century. It began in Bavaria in 1563, and quickly spread over southern Germany. But it was in France that the revived Roman Catholicism of the 16th century won its first great victory. The number of the 'Religionnaires' or 'Huguenots' in France had, in 1558, amounted to 400,000. From the massacre at Vassy by François de Guise in 1562 to the Massacre of St Bartholomew (August 23-24, 1572), four religious wars had lacerated France, and during the reign of Henry III. there were yet five of these desolating civil wars. The crafty saw-saw policy of Popes Sixtus V., Gregory XIV., and Clement VIII. secured every advantage afforded by the vicissitudes of the conflict, and it was not till after Henry IV. had gone over to Roman Catholicism that the pope in 1595 recognised him as the king of France. Liberty of conscience was extended to the French Protestants by the Edict of Nantes in 1598. From 1555 the ecclesiastical position of each German territory was dependent on the religious convictions of its ruler, and the members of the Lutheran Church had political equality with 'the old religion'; but the exclusion of the Reformed from that provision led to the isolation of Lutheranism from the great struggles of Protestantism in France, the Netherlands, and England. The principle *cujus regio, ejus religio*, by which subjects should follow the confession of their rulers, unavoidably led, in the political condition of Germany in the 16th and 17th centuries, to the breaking up of the Lutheran Church into a number of small national churches, and confused the development of Lutheran theology with the dynastic and family interests of the several courts. Stability was only attained

after the fearful struggle of the Thirty Years' War, when, at the Peace of Westphalia, Catholics and Protestants agreed to recognise each other's right to existence. The excellences of the Lutheran Church were the depth and power of its ascetic elements and its religious literature, especially its hymns, the noble expression of German mysticism. But the continuation and political maintenance of the Reformation has been mainly the work of the Reformed or Calvinistic churches. 'In a time,' says Häusser, 'when, of all the creations of the Reformation, Europe presented nowhere else any solid or lasting bulwark, the little Genevan state of Calvin sent out year after year its apostles into the world, and was the most dreaded foe of Rome, when nowhere else was there any resistance to her might.' In the Lutheran Church many of the Romish ceremonies were retained, and congregational organisation was neglected; whereas in the Reformed churches the congregations were organised on a democratic basis, that had nothing akin to the traditional principles of monarchical power. 'With the passive resistance of Luther men could not counteract the Caraffas, the Philips, and the Stuarts; that needed a school prepared for war to the knife; the only such school was Calvin's, and it everywhere took up the glove—in France, in the Netherlands, in Scotland, and in England.' Lutheranism has been established in Scandinavia and the countries along the Baltic, while the Reformed Church, which has throughout evinced a more radical character than the Lutheran, has especially prevailed in South Germany, Switzerland, France, the Netherlands, and Scotland.

In England, Edward VI., the successor of Henry VIII.—who had been recognised by the parliament in 1534 as 'the only supreme head in earth of the Church of England'—with the help of Cranmer, Latimer, and Ridley, completed the Reformation. The Common Prayer-book was introduced, and a confession of faith in 42 articles drawn up as the standard of the church's doctrine. After a period of persecution under Mary, the Anglican Church was established under Elizabeth in the closest union with the state. By Elizabeth all ecclesiastical disobedience was regarded as treasonable, and the legislation of her later years was directed against those who took offence at the ritual and the hierarchy, and were known as Nonconformists. English Puritanism (which may be dated from 1567, when its adherents began to separate from the Established Church) was at first only an opposition to the ceremonial elements which the Church of England still retained after its separation from Rome. The principle of Puritanism was reformation through the members of the church itself, as opposed to reformation originating with the crown. It aimed at the overthrow of the episcopal system, and the establishment of a strict system of discipline in the spirit of Calvin. Under Charles I. the Puritans were severely persecuted, and many of them emigrated to America, and were the early settlers of New England. English Puritanism in alliance with Scottish Presbyterianism gained in the Great Rebellion a complete victory over the monarchy, but in England the fruits of the victory fell to the Independents, who were the most consistent section of the party. The Synod of Dort in Holland (1618-19), which was regarded as an oecumenical council of the churches of the Calvinistic Reformation, had decided the controversy between the Arminians and Calvinists entirely in favour of the latter. The Westminster Assembly (1643-49), called by the Long Parliament, drew up the confession of the Puritans, which is closely akin to the resolutions of Dort, and is still the standard in the churches of Scot-

land. Later phases of Puritanism developed a great variety of sects, the Baptists and the Society of Friends, or 'Quakers,' being the most notable.

The Reformation in Scotland had received from John Knox a strictly Calvinistic stamp. The Protestant nobles (called the 'Lords of the Congregation') entered in 1557 for the first time into a 'Covenant,' and the Scotch Confession of Faith was ratified by the Scottish parliament in 1560. All the efforts of Mary, 'Queen of Scots,' to win Scotland back to Roman Catholicism were fruitless. The first National Covenant 'against all kind of Papistry' was signed by king and people in 1581, and frequently renewed. In 1592 the Presbyterian constitution was established. Yet under James I. and his successors determined efforts were put forth to make the Church of Scotland a province of the Anglican Church. The obtrusion of the Liturgy in 1637 was met by the Solemn League and Covenant in 1638.

During the Civil War and the Protectorate of Cromwell, Independency increased in numbers and in influence. Two fanatical sections of the party, the 'Fifth-Monarchy Men,' and the 'Levellers'—who aimed at complete separation of the church from the state, which they maintained should preserve an attitude of religious indifference—were repressed by the iron hand of Cromwell on their attempt to establish their principles by force of arms. The declaration of faith and order issued by the Synod of the Independents in 1658 is not different in its doctrine from the Westminster Confession. After the accession of Charles II. Episcopacy was re-established both in England and Scotland. On the 24th August 1662 two thousand ministers were ejected from their livings in the Church of England, because they refused to subscribe the second Act of Uniformity, which enjoined all ministers in England to declare their unfeigned assent and consent to the entire Book of Common Prayer. In the same reign, the successive Conventicle, Five Mile, Corporation, and Test Acts increased the civil disabilities of both Nonconformists and Catholics. The persecutions did not cease till the Revolution, when the Act of Toleration in 1689 extended religious liberty to dissenters, only requiring from them the payment of tithes to the Established Church.

In the 17th century a middle party within the Church of England, known as the 'Latitudinarians,' had endeavoured to exercise a mitigating influence on the violence of the disputes between the extreme Episcopians and the rigid Puritans. Hales and Chillingworth were in the first half of the century the leading exponents of the party, which later included the 'Cambridge Platonists,' Whichcote, John Smith, Cudworth, More, and even Simon Patrick and Tillotson. About the middle of the 17th century another movement began in England as a reaction against the religious extremes of the Great Rebellion. The principles of the English 'Deists' originated undoubtedly in the reaction from the religious excesses of the Cromwell period, but were more largely due to the progress of philosophy and the historical and natural sciences. They passed over to France, where they found a congenial soil under Louis XIV. and Louis XV., and, in presence of the Dragonnades and the persecutions of the Protestants after the revocation of the Edict of Nantes in 1685, developed into the Atheism and Materialism of the Encyclopédistes. These afterwards bore bitter fruit in the French Revolution—the religious issue of which proved,' says Hase, 'not only the necessity of religion for a civilised people, but also the national indispensability of a church.'

In Germany the reaction from the fanatical violence of the Thirty Years' War and the lifeless orthodoxy of the 17th century took the form

of Pietism. It began with the *collegia pietatis* founded by Spener about 1670, and the similar *collegia philobiblica* of Francke, professor at the university of Halle from its foundation in 1694. Halle became the centre whence Pietism spread on every side, and its influence, like that of Geneva under Calvin, extended to all the Protestant countries of Europe. The church of the Moravians, in the form in which it was renewed by Zinzendorf, is a daughter of Pietism, and the founder of Methodism testified that Moravianism was the first medium of his own inspiration. Pietism, with Moravianism, which inwardly rests on the same foundation, is, says Weingarten, 'the last fruit of that heart-religion, springing originally from Franciscanism, which consists in the closest vital fellowship of the individual Christian with Christ.' It laid great weight on strictness of conduct, and dwelt rather on regeneration and sanctification than on the Reformation doctrine of justification by faith. During the reign of Rationalism it appeared quiescent, but it revived in the present century, and in alliance with the orthodoxy which it formerly combated forms the predominant party in the Evangelical Church of Germany.

The founders of English Methodism did not aim at any new doctrine or order, but only sought, like the German Pietists, to deepen spiritual life, and make it more practical and fruitful. Methodist societies began to be organised in 1739, after Wesley and Whitefield had been excluded from the pulpits of the Established Church. These two leaders separated in 1748 on the question of predestination, Wesley holding the Arminian, and Whitefield the Calvinistic view. Ten years after Wesley's death his followers numbered 40,000, and in twenty years more increased to upwards of 100,000. Wesleyan Methodism and its numerous offshoots have been distinguished both in this country and in America for their evangelistic zeal and their influence over the common people; and their earnestness and success have been the means of imparting a healthful stimulus to the Church of England. About the end of the 18th century the influence of the Methodist movement extended into the Established Church, and issued in the formation of the 'Evangelical party,' which, centring in Cambridge, soon became the most energetic party in the Church of England. At Oxford, which from Laud's time had been the centre of the old 'High Church' party, began about 1833 the Tractarian movement, of which the first impulse came from the Evangelical revival; while in one of its sides, at least, it was a kind of aesthetic outcome of the Romantic revival in literature and art. No fewer than 150 of the clergy and leading laymen connected with the movement followed Ward and Newman (in 1845 and 1846) into the Roman Catholic Church, but the party, held together for nearly fifty years under the leadership of Pusey, has now fully identified itself with the Anglican Church as the 'Catholic Church planted in England.' Though 'Anglo-Catholicism' has driven large numbers into the Roman communion, it has succeeded in doing what Methodism a hundred years before attempted, and has brought new life into the Church of England. It bears a close affinity to Roman Catholicism in ritual and doctrine, but refuses to acknowledge the universal supremacy of the Bishop of Rome. The 'Broad Church' party, the third in the modern Church of England, traces its beginning to Coleidge, but in spirit and to a large extent also in teaching, is substantially identical with the old Latitudinarians and the Cambridge Platonists, who, with great spiritual earnestness and honesty, maintained for over a hundred years a large and

tolerant theology. The modern Broad Church party agrees with the Evangelical or 'Low Church' party in minimising the importance of apostolical succession and sacramental grace, and in attaching no intrinsic value to particular forms of ritual or clerical vestments; but unlike it demands a more liberal interpretation of dogmatic definitions, and a greater freedom in the subscription to creeds. In its preaching it aims at guidance rather than conversion, frankly contradicting the prevailing Evangelical teaching that attributes everything to sovereign grace and emphasises the complete corruption of unregenerate human nature. It has throughout advocated a bolder view of the applicability to Scripture of methods of criticism and exegesis that have found favour in Germany. One of its earliest leaders was the famous Dr Arnold, who advocated the great Hooker's theory of the identity of church and state—a kind of spiritualised Erastianism—as the only means of fully carrying out the realisation of Christianity on earth. It has added many illustrious names to the roll of English churchmen, among them Whately, Maurice, Frederick Robertson, Julius Hare, Kingsley, Thirlwall, and Stanley.

The standard of Anglican doctrine is fixed by acts of parliament in the Thirty-nine Articles of 1571, and in the Book of Common Prayer (1552, revised in 1559 and 1661). Not till the present century has the church's close connection with the state been loosened by a series of laws removing the civil and political disabilities of dissenters. The Church of England includes at most two-thirds (some say only one-half) of the population, and possesses the whole of the ecclesiastical endowments of the country. Its comprehensiveness is altogether unexampled; within no historic church in the world is to be found such divergency of honest opinion. Its enormous revival of activity during the last fifty years has struck its roots deeper into the religious heart of England, and though its disestablishment has often been proposed, the Church of England is so closely interwoven with the other institutions of the nation, and is so dear to the majority of the English people, that such a contingency must seem remote. In any event, the solidity and dignity of the Episcopal Church would retain for it the chief place among the ecclesiastical societies of England. Such hindrances to its efficiency as pluralities and non-residence have long been removed, the episcopate within England has been largely extended, and missionary bishops appointed to organise and extend foreign missions, while no less than thirty millions have been spent within thirty years upon the building and restoration of churches at home. Such agencies for relieving poverty and distress as sisterhoods and special missions have leaped into life, and in the Church Congresses (first, 1861) and Diocesan Conferences (first, at Ely, 1864) the door has been opened to the co-operation of laymen in church work. The growing demand for greater freedom of action on the part of the church, resulted (1852, and 1856) in an attempt to revive the powers of Convocation, in abeyance since 1717. In 1867 was inaugurated the first Lambeth Conference of prelates of the Anglican rite from all quarters of the world.

James I. gave the whole ecclesiastical endowment in Ireland into the hands of the Anglican clergy. The Irish branch of the Anglican Church, which only embraced one-eighth part of the population, was disestablished and disendowed in 1871 by the Irish Church Act of 1869. In the census of 1871 the Catholics of Ireland numbered 4,141,933; Episcopalians, 683,293; Presbyterians and non-Episcopal Protestants, 558,238.

Patronage had been abolished in Scotland in 1690, but was restored under Queen Anne in 1712.

The repeated protests of the General Assembly were disregarded, but with the gradual ascendancy of the 'moderate' party in the church itself, were discontinued, and the dissatisfied seceded from the Establishment, forming the 'Secession' and 'Relief' churches. In 1834 the Assembly passed the Veto Act, declaring that no pastor should be 'intruded on any congregation contrary to the will of the people,' and giving the congregation the right to veto the appointment of a presentee of whom they disapproved. After a ten years' conflict between the 'non-intrusionist' and 'moderate' parties, the former seceded from the Established Church, and formed the Free Church of Scotland in 1843. The United Presbyterian Church arose from the union of the Secession and Relief churches in 1847, and is now the third in importance in Scotland.

In the United States it is a part of the constitution that 'no religious test shall ever be required as a qualification to any office or public trust,' and that 'congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof.' 'This separation between church and state,' says Schaff, 'is not a separation of the nation from Christianity. . . . The American nation is as religious and Christian as any other in the world, and shows this plainly by its voluntary support of so many churches and sects; by its beneficent societies of every kind; by its church-going, and respect for the clergy, who are inferior to no class in respect and influence; by its strict sabbath-keeping, which has its equal only in Scotland; by its zeal for home and foreign missions; by its reverence for the Bible; by a veritable flood of religious books, tracts, and periodicals; and by the whole tone of its public morality.' Of Protestants, the Methodists and Baptists are the most numerous, especially among the lower classes and in the southern states; while the Presbyterians, Congregationalists, and Episcopalians have the greatest influence among the middle and higher classes. In 1880 the Roman Catholics had 6,375,630 communicants; Baptists, 2,687,231; Methodists (Episcopal) 1,564,105, and (non-Episcopal) 1,718,092; Lutherans, 944,860; Presbyterians, 693,249; the Congregationalists, 382,920; and Episcopalians, 345,841.

A great development of missionary zeal has taken place in the Protestant churches of Europe and America during this century, leading to a vast expenditure of life and money. Among civilised races like the Jews, Chinese, and Hindus, the success attained has been small compared with that among races to which the Christian missionaries have brought, along with the preaching of the gospel, a vastly superior civilisation, such as the natives of Madagascar and Polynesia. There are now a hundred missionary societies in Protestant Christendom, with about 5000 European and American missionaries, and about 30,000 native assistants, and raising every year more than 2½ millions sterling for the evangelisation of the heathen world. The Roman Catholic Church has by its colonies and conquests in the New World endeavoured to redress the balance of the Old. In South and Central America, Hayti, and the Spanish and French West Indies, the population is almost exclusively Roman Catholic; while in British North America the proportion of Roman Catholics is 42 per cent., and in Australia and Polynesia about 15 per cent. The largest and most important missionary institute of the Roman Catholic Church is the Propaganda, founded by Gregory XV. in 1622. The missions of the Benedictines, Cistercians, Premonstratensians, and especially of the mendicant orders, who penetrated Africa and North and South America, were from the 16th and 17th centuries almost eclipsed by those of the Jesuits. In the East and

West Indies, Japan, China, and Abyssinia, they have won over thousands to their society and church. While Protestant missions have aimed at saving individual souls, they have used every possible means to effect conversions, and have counted their converts in crowds. Their constant policy has been to ingraft Catholic ideas and usages on traditional prejudices and customs. In India they commended themselves to the great as Christian Brahmins and to the poor as apostles of freedom; in Japan they sided with the native nobility against the luxurious priestly class; in China they made their way to favour through geometry and astrology; in Spanish South America they took the oppressed natives under their protection, contended against slavery, and founded in Paraguay a socialistic theocracy of their own.

Ever since the Reformation the Roman Catholic Church has been growing more and more ultramontane, and this tendency has become most marked in the second half of the 19th century, largely through the increasing influence of the Jesuits. That order, suppressed in Portugal (1759), in France (1764), in Spain and Naples (1767), in Parma (1768), and by the bull 'Dominus ac Redemptor Noster' of Clement XIV. in 1773, was restored by Pius VII. in 1814. The golden days of the Jesuits were under Pius IX. (1846-78), who gradually passed entirely under their influence. The Jesuit generals, Father Roothaan (1829-53) and Father Beckx (1853-84), called the 'black popes,' reigned in Rome side by side with the 'white popes,' Pius IX. The dogma of the Immaculate Conception, which the Jesuits maintained against the Dominicans, was promulgated by the pope in 1854, and ten years later the *Encyclica and Syllabus* proclaimed to the world that the political and ecclesiastical theories of Jesuitism were accepted by the holy see. The Jesuits acquired considerable influence in France under Napoleon III., but were expelled in 1880. In Italy, since the downfall of the pope's temporal power (1871), they are restricted to Rome, and they were excluded from Spain and Mexico (1868), from Germany (1872).

The famous canon expressed by Vincent of Lerinum in 434: 'Quod semper, quod ubique, quod ab omnibus creditum est,' has been the formal principle of Catholicism throughout its history. At first it fell to the bishops in the synods to decide whether any particular doctrine bore these three marks of Catholicity. Sometimes one synod set aside the resolutions of another, and even at the oecumenical councils the whole Church was never represented in the same proportions. The supreme authority of the pope was the only means to secure absolute unity, and neither the defenders of the 'episcopal system' at the medieval councils nor the Gallicanism of the French clergy (set forth in their declaration of 1682) were able to interpose an effective resistance. To secure the Papacy from all such opposition in future, the Jesuits persuaded Pope Pius IX. to have it decreed by the Vatican council that only the pope is the infallible head of the Church. Leo XIII. has set his seal upon the work of Pius IX. by restoring, in 1880, to the order of the Jesuits all the privileges it enjoyed before its dissolution. The ancient conflict between emperor and pope, recently revived in the 'Kulturkampf,' ended (1883-86) in a victory for the Papacy, by the withdrawal of the 'May Laws' and the reversal of the German ecclesiastical policy pursued since 1872.

At the present day there are 207½ million Roman Catholics, only 115 million Protestants, and 83½ million Greek Christians; while the non-Christian population of the world is about 1018 millions.

The primary sources of Church History are: (1) Original documents, such as the records and decrees of church councils; the official publications of

bishops and popes (pastoral epistles, bulls, briefs, decretals, and constitutions); laws relating to ecclesiastical affairs, issued by sovereigns, chancellors, or parliaments; liturgies and service-books, rules of religious orders, symbolical books and confessions of faith, sermons and treatises of theologians and ecclesiastical leaders, journals and reports of eye-witnesses, and letters of contemporaries eminent in church or state. (2) Monuments, such as ecclesiastical buildings, pictures, sculptures, inscriptions, vessels, &c. Among the secondary sources are calendaries, martyrologies, and necrologies; traditions, annals, and chronicles—all requiring to be sifted by criticism, the farther their date from the period to which they refer.

The earliest church historian whose writing is extant is Eusebius of Casarea, who made use of the earlier works of Hegesippus (about 150 A.D.) and Julius Africanus (3d century). The history of Eusebius, extending to 324 A.D., was continued by Socrates to 439, Sozomen to 423, Theodoret to 428, Philostorgius to 425, Theodore to 527, and Evagrius to 594. The chronicle of Eutychius of Alexandria, written in Arabic, comes down to 937. Nicephorus Callisti (1330) closes the series of the Greek church historians. The Byzantine civil historians from 500 to 1500 contain valuable materials for church history. The earliest Latin historians of the Church were Rufinus, who wrote a translation of Eusebius, and brought it down to 395; Sulpicius Severus, 'the Christian Sallust,' extending to 400; Orosius to 416; Cassiodorus, who combined Socrates, Sozomen, and Theodoret into a text-book, the famous *Historia Ecclesiastica tripartita*, which was the standard down to the Reformation; and Jerome, whose translation of Eusebius, and continuation to 378, was followed by the chroniclers Prosper of Aquitaine, Idacius, and Marcellinus. Of medieval writers of special histories the most notable are Jornandes (550); Gregory of Tours (540-595), who wrote the chronicles of the French Church in the 5th and 6th centuries; Bede, the father of English church history, which he narrated to the year 731; Paul the deacon (760), author of a history of the Lombards; and Adam of Bremen, the chief authority on the northern churches from 788 to 1072. The *Dialogus Miraculorum* of Caesarius of Heisterbach throws great light on his own age (first half of 13th century). Besides the *Liber Pontificalis*, a history of the popes to 885, which was probably the work of various authors, general church history was written by Anastasius of Rome and Haymo of Halberstadt in the 9th century, by the Norman monk Ordericus Vitalis, and the cardinals Petrus Pisanus, Pandulf, and Boso in the 12th century; in the 13th, by Martinus Polonus, whose *Chronica summorum Pontificum Imperatorumque* was the most popular history-book of the middle ages; in the 14th, by Ptolemy of Lucca; and in the 15th, by Antoninus of Florence, whose work comes down to 1459. Laurentius Valla's attack on the legend of the 'Donation of Constantine' appeared in 1440.

The Reformation, at first more productive in exegesis than in history, awoke to the necessity of justifying itself by the Church's development in the past, as well as by the statements of Scripture. After the Peace of Augsburg, a society of Lutheran theologians at Magdeburg, headed by Matthias Flacius (Illyricus), compiled a comprehensive history, arranged in 13 folio vols., each embracing a century. The *Magdeburg Centuries* was answered by the *Annals* of Caesar Baronius, in 12 folio vols., which was followed by the histories of Hottinger, Spanheim, and Samuel and Jaques Basnage in the Reformed Church, and of Pagi, a Franciscan monk, who also criticised Baronius. The history of the Council of Trent was written

by Sarpi and Pallavicino. Church history was afterwards cultivated in the Roman Catholic Church chiefly by the Benedictines of St Maur and the Oratorians in France. Alexander Natalis, Fleury, Bossuet, and the Jansenist Tillemont, were the most celebrated writers. Protestant historians had been for nearly a century employed in polemical writing, and the compilation of dry summaries of events and dates, when Georg Calixtus gave a new impulse to the study by a series of dissertations urging the value of unprejudiced investigation. The mystic Gottfried Arnold maintained the right of heretics against the Church in his *'Impartial' History* (1699), and was answered by Weismann, George and Franz Walch, and S. J. Baumgarten. From the 16th century down to the 18th the Church of England was ably vindicated in the light of history by Jewel, Hooker, Pearson, Beveridge, Cave, and Bingham. Strype's *Annals* and *Ecclesiastical Memorials*, and Neal's *History of the Puritans*, are the authorities for the Reformation and the Puritan movement in England. Of the other English writers of church history down to the present century, the chief names are those of the martyrologist Foxe and Archbishop Parker in the 16th century; Usher, Fuller, Dugdale, and Burnet in the 17th; and Jeremy Collier, Echard, Calamy, Bower, Lardner, and Milner in the 18th. Knox's *History* (1586) is the authority for the Reformation in Scotland. Scottish church history was written in the 17th century by Row, Spottiswood, and Calderwood; and in the 18th by Defoe and Wodrow. Mosheim was the first to establish the study of ecclesiastical history on a scientific basis, and the sceptical Senler, though, according to Hase, 'without all style and feeling for the peculiar conditions of antiquity,' founded the criticism of the sources. The huge work of Schröckh, in 35 vols., begins the so-called 'pragmatical' school of church historians, which laboured to collect external facts and relate them to their causes, and was also represented by Spittler, the elder Henke, Stäudlin, and Planck. In the early part of the 19th century, Ernst Christian Schmidt, in 6 vols., presented an impartial statement of facts. Gieseler produced a masterpiece of scientific investigation, with the most valuable extracts from the sources accompanying the text, a method which had been previously employed by Danz, and was also cultivated by Niedner. In modern Protestant church history the greatest work is that of Neander, which, in contrast with the pragmatical histories, dwells mainly on the inner development of the Church in doctrine, worship, and religious life. He has been followed by Jacobi and Hagenbach. Among academic treatises on church history the most notable are those of Guericke, H. Schmid, Lindner, and Kurtz, all from the Lutheran point of view; those of Herzog and Ebrard in the Reformed Church; and the very able and interesting lectures of Hase, Hase, and Rothe. Recent church history dates from F. C. Baur, who in separate treatises covered the whole field. The effect of his work on the first three centuries has been to turn the attention of many writers for more than a generation to the study of the early church. The contention of Baur, and his disciples Schwegler and Zeller, which represented the original apostles of Christ as persistently struggling for the perpetuity of 'Petrinism' against Paulinism, and interpreted the New Testament to prove this theory, has been considerably discredited by the investigations of Ritschl, Weizsäcker, Lechler, Harnack, Weiss, and De Pressensé.

In the Roman Catholic Church the study of church history has been pursued with great energy. The *Acta Sanctorum* of the Bollandists, begun in the 17th century, have reached their 63d volume.

Of the councils, the chief collection is that of Mansi, in 31 vols., and history that of Hefele in 7 vols. In the earlier part of the 19th century the chief writers in Germany were Count Stolberg (whose work in 15 vols., extending to 430 A.D., has been brought down to 1300 in other 17 vols. by Kerz), Katercamp, and Möhler, who was the first of a new school of thoroughly scientific historians, to which Ritter, Locherer, Döllinger, Alzog, and Kraus belong, while the works of Cardinal Hergenröther and of Brück have a strong ultramontane bias.

English writers on general church history are still largely dependent on the labours of German scholars. There is no English church history worthy of a place beside the works of Neander, Gieseler, and Hagenbach.

Of other 19th-century writers may be mentioned Hinds, Burton, Kaye, T. Price, Marsden, Lathbury, Hardwick, Maurice, Blunt, Milman, Hook, Newman, Stanley, Creighton, Robertson, Wordsworth, Abbey and Overton, Haddan and Stubbs, Perry, and Stoughton in England; Cook, M'Crie, Hetherington, Welsh, Lee, Grub, Tulloch, Skene, and Gunningham in Scotland; Reeves and Killen in Ireland; Schaff, Allen, and Fisher in America; Gfrörer, Ranke, Heppel, Henke, Overbeck, Hansrath, Keim, Häusser, Kahnis, Schürer, Lipsius, Hilgenfeld, and Langen in Germany; and Matter, Bungenier, Capetigue, De Montalembert, Aubé, D'Aubigné, Renan, De Broglie, Michaud, and Chastel in France.

For the remarkable development of the literature on the life of Christ during the last fifty years, see the article on JESUS.

Churchill, CHARLES, satirist, was born in Westminster in 1731. After leaving Westminster School, where he was contemporary with Colman, Robert Lloyd, Cowper, and Warren Hastings, he did not enter Oxford or Cambridge, being apparently disqualified by an imprudent Fleet marriage at seventeen. In 1756 he was ordained priest, 'through need, not choice,' and at his father's death in 1758 he was appointed to the curacy and lectureship of St John's, Westminster, the poor emoluments of which office he strove to eke out with teaching. But he was hopelessly improvident and already dissipated; accordingly, after a bankruptcy of but five shillings in the pound—and that paid only by the aid of Robert Lloyd's father—a formal separation from his wife, and a course of unclerical indecorum and dissipation that called forth the remonstrances of his dean and the protests of his parishioners, he slipped his neck from the orders which he wore so awkwardly, and cast himself

entirely upon the town (January 1763). His *Rosciad*, published in 1761, had already made him famous and a terror to all the actors of the time. The poem was modelled on Dryden, and had real talent and vigour, as well as scurrilous and unsparing personality to commend it. Later in the same year, in *The Apology*, he made a savage onslaught on his critics, and particularly Smollett. *Night* (1762), a long poetical epistle addressed to Lloyd, and suggested by Day, Armstrong's somewhat unwelcome poetical epistle to 'gay Wilkes,' contained some nervous lines, but was on the whole a poor production marred by an impudent bravado of honesty, as if it were some justification of misconduct to make a candid avowal of it. *The Ghost* (1762) is an incoherent and tiresome poem of over four thousand lines in octosyllabic metre, only remembered now for the attempt to satirise Dr Johnson as 'Don Pomposo' on occasion of the Cock Lane ghost-story, and the much more warrentable ridicule cast upon Whitehead the laureate. Churchill next helped Wilkes in the *North Briton*, and heaped timeous ridicule upon the Scotch in *The Prophecy of Famine* (1763), an admirable satire, bright with wit sharpened into stinging verse—undoubtedly his best work. 'It is indeed falsely applied to Scotland, but on that account may be allowed a greater share of invention,' says Boswell, with characteristically wrong-foot-for-most but whimsically ingenious reasoning. Later in the same year appeared Churchill's *Epistle to Hogarth*, for which the great caricaturist paid the poet by gibbeting him to all future time as a bear in torn clerical bands and ruffles, with a pot of porter, and a club inscribed 'Lies and North Britons.' Other works of Churchill's were *The Duellist*, an onslaught on Wilkes' assailants in the House of Lords; *The Author*, which pleased the critics and even Horace Walpole; *The Conference*, interesting especially for one redeeming feature—a singularly touching and true confession of remorse for the seduction (but not desertion) of a Westminster tradesman's daughter; *Gotham*, a long and ambitious exposition of his political ideas; *The Candidate*, a splendid attack on Sandwich; *The Farewell*, *The Times*, and *Independence*, the last containing an interestingly unflattering portrait of the poet by his own pen, in which he laughs at his burly frame and rolling gait—'much like a porpoise just before a storm.' Meantime the satirist had prospered and gained enough not only to pay off all his old debts, but to help others, for no man was ever more faithful and unreserved in love towards his friends than this sinning and repenting prodigal. In the October of 1764 he crossed to Boulogne to see Wilkes, was seized suddenly with a fever, and died on 4th November. Just before the end he sat up in bed to bequeath annuities of £60 to his wife and £50 to his mistress, for which, however, there proved to be no funds. His body was buried at Dover, and on a slab above his grave was inscribed with less than dubious truth the line from his poem *The Candidate*: 'Life to the last enjoyed, here Churchill lies.' Fifty-four years later Byron, leaving England for the last time, stood beside his tomb, his mind filled with reflections on 'the Glory and the Nothing of a Name,' which he shaped into a poem scarce worthy of its theme.

Churchill left two unfinished satires—*The Journey*, broken off at a line of sadly ominous significance: 'I on my journey all alone proceed;' and the severe and masterly *Dedication* to the arrogant Warburton. His satires are for the most part long since forgotten. Though neither 'a blockhead' according to Johnson, nor 'the great Churchill' as described by Cowper with all an old schoolfellow's extravagance of admiration, he was yet a satirist of

high capacity, with a happy knack of turning strong and honest thought into nervous and memorable verse. At the same time he lacked the chief essentials of true satire, a real insight into the heart of man and that rarest power of happy exaggeration, of preserving likeness in unlikeness and verisimilitude in distortion. A fatal volubility in rhyming, a kind of boisterous but unequal energy, and an instinctive hatred of wrong, manly and honest, although often scarce to be distinguished from the mere reflex reaction of natural spleen and obstinacy, combined to make him the hero of the hour and its ephemeral interests, but was not equipment enough for a Dryden, a Juvenal, or even a Butler. See Forster's *Historical and Biographical Essays* (vol. ii. 1858), and Southey's *Life of Cowper*.

Churchill, LORD RANDOLPH HENRY SPENCER, third son of the seventh Duke of Marlborough, was born on February 13, 1849, and educated at Eton and Merton College, Oxford. Lord Randolph was first returned for Woodstock in 1874; but it was not until after the general election of 1880 that he became prominent in politics, when he appeared as the leader of a guerilla band of Conservatives known as the 'Fourth Party.' He was frequently in collision with his leaders on questions of party organisation and the conduct of the Opposition; but his vigorous attacks on Mr Gladstone's policy, both foreign and domestic, were of unquestionable value to the Conservative cause. Towards the end of Mr Gladstone's ministry Lord Randolph began to have a considerable following among the younger Conservatives, who regarded him as the future leader of the Tory Democracy. After a plucky attempt to defeat Mr Bright at Birmingham in 1885, Lord Randolph was returned for South Paddington. He was Secretary for India in Lord Salisbury's first ministry (June 1885–January 1886), his period of office being marked by the annexation of Burma. From July to December 1886 he was Chancellor of the Exchequer and leader of the House of Commons, when he resigned, being resolved, as he wrote to Lord Salisbury, to sacrifice himself on the altar of thrift and economy. His attacks on the spending departments thenceforward were most incisive; but on most other points he spoke and voted steadily on the Conservative side. Lady Randolph Churchill, *née* Jerome, who is of American birth, has given most valuable assistance to her husband in his electoral contests, and is a prominent member of the Primrose League.

Churchill River, of Canada, rises between the north branch of the Saskatchewan and the Athabasca, under 55° N. lat., and flows generally NE. through a series of lakes, first as the Beaver, then as the Missinippi, and finally as the Churchill or English River, to Hudson Bay, which it enters near Fort Churchill, after a course of nearly 1000 miles. There is plenty of traffic during summer by canoes, which are conveyed by land portage past the largest of the stream's many rapids. The natural advantages of Churchill harbour have caused it to be regarded as a possible terminus for the railway from Winnipeg, and the starting-point of the direct sea route to England by Hudson Bay and Hudson Strait.

Churching of Women, a religious usage prevailing in the Christian church from an early period, of women, on their recovery after child-bearing, going to church to give thanks. It appears to have been borrowed from the Jewish law (Lev. xii. 6); and the earliest express mention of it is in the pseudo-Nicene Arabic canons. No ancient forms for the purpose are extant, and those in actual use are of mediæval date. The Greek rite is only partially concerned with the woman, being also the presentation of the new-born child in the

church on the fortieth day after birth (a usage based upon Luke, ii. 22); the Latin rite, contrariwise, is exclusively a benediction of the woman, and is restricted to such as have borne children in wedlock. It is not obligatory, nor included among strictly parochial rights, but only recommended as a pious and laudable custom. In the Church of England, also, a service for the churching of women, differing little from the medieval rite, finds a place in the Prayer-book. By the Presbyterian and Independent churches of Britain and America it is rejected as having no Scripture warrant.

Church Music. See ANTHEM, ANTIPHONY, CHANT, CHOIR, GREGORIAN TONES, HYMNS, MASS, PLAINSONG, SERVICE.

Church-rates, in England, a tax or assessment laid on the parishioners and occupiers of land within a parish, by a majority of their own body in vestry assembled, for the purpose of upholding and repairing the fabric of the church and the belfry, the bells, seats, and ornaments, the churchyard fence, and the expenses (other than those of maintaining the minister) incident to the celebration of divine service. The parishioners are convened for this purpose by the Churchwardens (q.v.). The Chancel (q.v.) being regarded as belonging peculiarly to the clergy, the expense of maintaining it is laid on the rector in receipt of the great tithes, though custom frequently lays this burden also on the parishioners, as in London and elsewhere.

The church-rate was anciently a charge on parishioners in respect of their lands, according to their area and the stock thereon, but it was a personal, not a real charge; and every bishop was bound to contribute to the repair of the public 'baptismal churches' of his diocese (i.e. churches with public baptisteries annexed to them). The responsibility of the parishioners for the repair of their parish church is recognised as early as 1018 by a law of King Canute, enacting that 'all folk shall of right help the church-bot,' which was the sum levied for repairs of churches. The care of the fabric of the church, and the due administration of its offices, are laid upon the minister and the churchwardens conjointly, and the latter may be proceeded against by citation in the ecclesiastical courts, should they neglect these duties. But there is no legal mode of compelling the parishioners as a body to provide the rate; and this circumstance has occasioned much difficulty in imposing the tax in parishes in which dissent is prevalent, and has led to many churches falling into a partially ruinous condition. The proper criterion for the amount of church-rates is a valuation of the property within the parish, grounded on the rent that a tenant would be willing to pay for it. Glebe land, the possessions of the crown in the actual occupation of the sovereign, and places of public worship, are not liable for church-rates; but there is no other exception as regards immovable property, and in some parishes custom even extends it to stock-in-trade. It has been often decided in the courts that a retrospective church-rate—i.e. a rate for expenses previously incurred—cannot be validly imposed. Much difficulty has been experienced in recovering the rates imposed by the parish on individuals refusing to pay. Previous to 53 Geo. III. chap. 127, the only mode was by suit in the ecclesiastical court. That statute, however, in all cases under £10, empowered the justices of the peace of the county where the church was situated, on complaint of the churchwardens, to inquire into the merits of the case, and order payment. Against the decision of the justices an appeal lies to the quarter-sessions. In 1868 an end was put to all parochial contentions by enacting that no suit or proceeding

should thereafter be allowed in any court to enforce or compel payment of a church-rate, except where a local act authorised this rate. But except so far as related to the compulsory payment of these rates, the churchwardens might, as before, make, assess, receive, and deal with such rates. In each district parish the inhabitants may treat their own church as if it were their parish church, and make and receive rates for the repair of the same. A body of trustees may now be appointed in each parish to receive contributions for ecclesiastical purposes in the parish. The result of this act of 31 and 32 Vict. chap. 109, is thus not to abolish church-rates, but rather to convert them into voluntary payments; allowing, as it does, all faithful adherents of the church to contribute, as before, to the repairs of their own churches. But it has been found practically inapplicable, and its enabling clauses are rarely acted on, so that voluntary contributions have in nearly all cases been substituted for rates.

In Scotland the burden of upholding extra-burghal parish churches is imposed on the parish heritors; and where the parish is partly within burgh and partly in the country, the expense must be borne by heritors and proprietors of houses, in proportion to their real rent. See SCOTLAND (CHURCH OF); also DISSENTERS, PARISH, HERITORS, FEuars. In Ireland church-rates were abolished in 1823.

Churchwardens are the modern representatives of the ancient *Seniores Ecclesiastici*, laymen who were custodians of church goods and ornaments, and agents for ecclesiastical affairs on their temporal side, but had no share in church government, nor any right of session in synods. In England they are lay ecclesiastical officers, elected yearly at Easter, sometimes by the parishioners and minister jointly, sometimes by the minister alone, sometimes by the parishioners alone, by the select vestry, by the lord of the manor, or by the outgoing wardens, but most commonly (and always in the case of new parishes) the incumbent chooses one and the parishioners the other. They are appointed for the purpose of protecting the edifice and goods of the church, keeping order in the church during public worship, seating the parishioners, and executing other parochial functions. They are admitted to their office by the Ordinary, usually the bishop of the diocese, and are his officers, as well as representatives of the lay parishioners. But their office in this respect is only one of observation and report, and they cannot interfere directly with the incumbent, if in their mind violating the laws ecclesiastical, but must simply deliberate the matter to the bishop by presentment at his visitation. They are also usually appointed as trustees of sequestrated benefices. Certain classes are ineligible for election as churchwardens, such as Jews, minors, aliens, and persons convicted of felony, fraud, or perjury; and there are many exempted from serving, though eligible if elected, such as peers, members of parliament, justices, clergymen; Roman Catholic ecclesiastics, dissenting ministers, officers of the army and navy, barristers, solicitors, &c. They are generally two in number, but the office of churchwarden is a single one, of which each warden holds an undivided moiety, so that they cannot legally act independently of each other. There is no officer in the Roman Catholic Church precisely corresponding to the English churchwarden. The closest analogy is found in the trustees of the church fabric fund of the parish. These are named *Marguillier* (Lat. *matricularius*) in France, and are three in number, elected by the other members of the parish council, one of them going out of office yearly. They have the charge of the ordinary expenditure of the church, the superintendence of its minor officials, such as the

beadle, &c., and the general conduct of the civil part of parish business. See CHURCH-RATES, PARISH, VESTRY; and Prideaux's *Practical Guide to the Duties of Churchwardens* (15th ed. 1886).

Churchyard. The churchyard in the earliest days of Christianity was often prior in time to the church itself. The Roman law so strictly protected the area within which stood monuments of the dead from violation, and even from the incidence of those acts of ownership to which other lands were subject, that the Christians found it usually feasible to obtain security for their burial-places, which would have been by no means equally extended to their places of religious assembly. For this reason, and also from personal feeling, they were in the habit of assembling for worship at the tombs of martyrs, and it became usual to erect churches close to these. But where the church was prior in point of time, it was not at first usual to bury within the curtilage or precinct of the building, and the cemeteries were entirely apart. A few instances of interment within the churchyard proper appear as early as the 4th century, but it is not till after the 6th that it became a general custom. The first direct evidence of the formal consecration of a burial-ground is in this same era (Greg. Turon., *De Gloria Confessorum*, chap. 6), but the usage most probably dates much earlier, because such dedication was customary in respect of all things and persons set apart for religious purposes. The belief in the efficacy of prayers for the dead had much influence in promoting burial within the precincts of churches, as those attending for worship might be expected to pray for those interred close by; and this reason, adduced by Gregory the Great, was embodied in the Canon Law.

The introduction into England of the custom of burying in churchyards is ascribed to Cuthbert, Archbishop of Canterbury (741-758), and by common law the freehold of the churchyard belongs to the rector of the parish, qualified by the rights of the parishioners, who, in their turn, are bound to repair the fence at their own cost, unless there be a local custom for the owners of adjoining lands to repair so much of the fence as marches with their ground. The trees and grass growing in the churchyard also belong to the rector, but though he may depasture his sheep or cattle there, he is not at liberty to cut down the trees unless to provide timber for repairing the church. Until the enactment of the statute 43 and 44 Vict. chap. 41, no form of burial service except that of the Church of England could legally be used in any churchyard; but under that act notice may be given to the incumbent or officiating minister, by the representatives of any deceased person, that they intend the burial to be either without any religious service at all, or with some 'Christian and orderly religious service' other than that of the Church of England. The widest interpretation is to be put on this definition, so as to include all services used by any society professing to be Christian, but non-Christian rites are specifically excluded from the operation of the statute. Churchyards, even if closed for purposes of burial, cannot under the existing law be converted to secular uses, and the freehold continues to vest in the incumbents of the parishes where they are situated. Any person guilty of violent or indecent behaviour in a churchyard, or disturbing any clergyman conducting a burial therein, is liable by 22 and 23 Vict. chap. 32, sect. 2, to a penalty of £5 or two months' imprisonment, and for damage to any monument or fence, under 24 and 25 Vict. chap. 97, sect. 39, to imprisonment not exceeding six months with or without hard labour. See BURIAL, CEMETERY.

Churchyard Beetle. See BLAPS.

Churl. See CEORL.

Churns are machines used for the production of butter from cream or from whole milk. By agitation the butter globules are thrown against each other until after a period which varies in length with the quality of the butter-fat, the temperature, and the condition of 'ripeness,' or incipient acidity of the cream. Churns are of great variety in form and dimensions, from the ladies' glass hand churn producing a few ounces of butter at a time, to one driven by water, steam, or horse-power, and churning the whole milk of a dairy at one operation. The *plunge* churn or *thump* churn is one of the oldest and most simple varieties. The common *upright hand* churn seen in country places is perhaps the best known form of it, but the principle is equally applicable to larger churns. The *box* churn, either oblong or cubical, is stationary like the latter, the action being brought about by 'dashers' or 'works' made to revolve on a horizontal spindle passing through its centre.

Revolving churns, taking the shape of a box or barrel, are supported from two points on a rigid framework, so that the whole body of the churn is turned round at the rate of forty to fifty revolutions per minute by a crank handle after the fashion of an ordinary grindstone. Sometimes the motion is a simple rotatory one, as when the barrel is supported from the centre of both ends, giving it the position of a barrel rolling on the ground. It may also be hung from two corresponding points, one on each side, and occupy an upright position while at rest. The action is then called 'end over end.' An eccentric motion is given by hanging the body unevenly. These churns also contain 'dashers' or 'diaphragms' which increase the agitation of the cream. Their great advantage is the ease with which they can be worked—a matter of first importance where hand labour is employed. *Swinging* or 'cradle' churns are increasing in favour, because they are so extremely easily worked, inexpensive, and simple, and because they contain no movable 'dashers,' which demand much care and labour in keeping them sweet and clean. The body, consisting of an elongated box, may be suspended by four chains or thin iron rods, or it may be carried on four flat, flexible iron supports. It is pushed so that it swings backwards and forwards, giving the cream within a course which assumes the form of the figure 8. The *Holstein* churn is upright and rigid. Its dashers, which are attached to a perpendicular shaft, are worked at high speed. This enables the operator to reduce the temperature of the cream by nearly 10° F., as compared with the temperature at which it is put into an ordinary churn. Churning is then done in summer at 50° F., which gives the resulting butter-product much greater firmness and a better texture. See BUTTER and DAIRY.

Churru. See HEMP.

Chusan, the principal of the group of islands known as the Chusan Archipelago, lies about a mile off the east coast of China, opposite Ningpo. It has an area of over 230 sq. m., and a pop. of 200,000 to 250,000; and although mountainous in the centre, it is generally fertile, and everywhere carefully cultivated. Ting-hai, the capital, a walled town about 3 miles in circumference, is, from its position on the route between Canton and Peking, close to the great ports of Shanghai and Ningpo, a place of both strategic and commercial importance, and its land-locked harbour is a busy shipping centre. There are few manufactures, but its carved work and silver wares are in repute, and cordage, matting, and fans are exported. It was taken by the British in 1840, and

held till 1841, the close of the war; and in 1860 it was again occupied by an English force. Pop. 30,000 to 40,000.—The most remarkable of the surrounding group is the sacred island of Pu-tu, a mile E. of Chusan, covered with Buddhist temples, pagodas, and monasteries, and inhabited by upwards of a thousand monks. The chief monastery is one of the richest in China.

Chutney, an East Indian condiment, very largely used in India, and to a considerable extent in Britain. Indian chutney is a compound of mangoes, chillies or Capsicum (q.v.), and lime-juice, with some portion of other native fruits, such as tamarinds, &c., the flavour being heightened by garlic. It is sometimes manufactured for sale in England. Families occasionally make it for their own use, and employ the following ingredients: Chillies, 1 to 1½ lb.; apples, 1 lb.; red tamarinds, 2 lb.; sugar-candy, 1 lb.; fresh ginger root, 1½ lb.; garlic, ½ to ¾ lb.; sultana raisins, 1½ lb.; fine salt, 1 lb.; distilled vinegar, 5 bottles.

Chyle, CHYME. Food, having been partially digested and absorbed in the stomach, is then passed on into the small intestine. It is of a pulpy consistency, and is termed *chyme*. Both digestion and absorption continue in the small intestine (see DIGESTION). Of the digested chyme a portion finds its way directly into the blood-vessels of the intestine. Nearly all the fat, however, passes into a special system of Lymphatics (q.v.) termed *lacteals*. These lacteal vessels lie in the walls of the intestine, and, during the fasting condition, are filled with a watery-looking fluid called lymph, which exudes from the neighbouring blood-vessels. During absorption, however, the lacteals, in addition, become filled with the absorbed fat which is in a state of minute subdivision. This gives the *chyle*, as it is now termed, a milky appearance. The lacteals convey the chyle into a large vessel, the thoracic duct, which finally conducts it into the large veins at the root of the neck, where it mixes with the blood. One may observe the lacteals on opening the abdomen of an animal killed some few hours after a full meal containing fat. When filled with chyle they resemble white threads branching in the substance of the mesentery—a membrane stretching between the intestine and the back of the abdomen. Microscopically chyle consists of a fluid containing minute fat-globules and a few corpuscles, similar to white blood-corpuscles. Chyle is alkaline in reaction, and coagulates when withdrawn from the body. It may be looked upon as lymph plus the fat which has been absorbed. It contains (1) Proteids, such as serum-albumen, serum-globulin, and fibrinogen. Fibrin is formed during the process of coagulation. (2) Fats—palmitin, stearin, olein, and also cholesterolin and lecithin. (3) Extractives, notably urea and grape-sugar. (4) Salts, especially sodium-chloride. See LYMPH, NUTRITION, DIGESTION.

Cialdini, ENRICO, was born at Castelvetro, Modena, August 10, 1811. Designed for the medical profession, he studied at Parma, but by his share in the abortive insurrection of 1831 was forced to escape to France. He joined the foreign legion raised by Dom Pedro against the Miguelists, but, in 1835 passing over to the Spanish service, he fought against the Carlists, and was made colonel. When Charles Albert headed the Italian rising in 1848, he hurried to Italy; in the struggle which ensued he received a dangerous wound, and fell into the hands of the Austrians. On his release, he was employed by the Sardinian government to reduce the volunteers to discipline, and fought at the head of his new regiment in the brief campaign of 1849. In the Crimea he com-

manded a division of the Sardinian contingent; and on his return was appointed aide-de-camp to the king. He was intrusted by Cavour with the formation of the famous Cacciatori delle Alpi. In the war of 1859 the victory at Palestro was his chief exploit. In 1860 he defeated the Papal army at Castelfidardo; in 1861 Gaeta and Messina yielded to him. Created Duke of Gaeta, and for a few months governor of Naples, he had to act against Garibaldi in the second Sicilian expedition (1862). In 1864 he became a senator; and in the war of 1866 he occupied Venice almost without a blow. In 1876 he was sent as ambassador to Paris, but he retired in 1881, and received the post of one of the two generals of the army.

Cibber, COLLEY, actor, manager, and dramatist, was born in Southampton Street, Bloomsbury, London, on 6th November 1671. He was the son of Caius Gabriel Cibber, a sculptor of some note, born in Holstein in 1630, whose best-known work is the *basso-relievo* on the pedestal of the London Monument. He was educated at the free school of Grantham, in Lincolnshire; and in 1690 embraced the profession of an actor, joining the famous company of the Theatre Royal in Drury Lane. At this theatre, on the fortunes of which he exercised so important, an influence, he remained, with one or two short intervals, during the whole of his theatrical career of forty-three years. At first he made very slow progress, and it was not till the secession from Drury Lane in 1695 of all the chief actors, that Cibber had an opportunity of showing how good a comedian he was. In January 1696 Cibber's first comedy, *Love's Last Shift*, was acted at Drury Lane, the author playing Sir Novelty Fashion. By this production his fame, both as dramatist and actor, was securely fixed; and he went on increasing in reputation till, after the secession in 1709, he was chosen one of the managing actors of the Haymarket Theatre. In 1710 Cibber and his partners were transferred to Drury Lane, in the direction of which Steele was in 1714 associated with Cibber, Wilks, Booth, and Dogget. Various changes occurred in the personnel of the management, which was finally broken up at the retirement of Cibber in 1733. During their management the associated actors wrought a vast improvement in the condition of the stage. Plays became more decent; the dissipated loungers that were accustomed to haunt the side scenes were denied admittance, at the risk, as Cibber relates, of the managers' lives; the pecuniary affairs of the theatre were managed with regularity; and the whole atmosphere of the theatre gained in respectability. As an author Cibber contributed largely to the improvement in decency which followed Jeremy Collier's famous philippic in 1698; and it must always be remembered to his credit, that in his comedies he does not rely for his ludicrous effects on the outraged husband who had almost invariably been the butt of previous dramatists. His greatest work, however, is his *Apology for the Life of Mr Colley Cibber, Comedian* (published in 1740; new ed. by R. W. Lowe, 1888), one of the most interesting autobiographies in our language. On the death of Eusden in 1730, Cibber, who was a devoted partisan of the Protestant succession, was appointed poet-laureate, in which office he wrote odes which were justly the object of universal ridicule. On this account, among others, he was ferociously attacked by Pope, who, in revenge for a damaging retaliatory pamphlet, elevated Cibber to the throne of Dullness in the 1743 edition of *The Dunciad*. The crime of dullness was, however, the last that could be charged to Cibber, who was vain, pert, a loose liver and a loose talker, but not a dullard. Cibber died suddenly on 11th December

1757. His wife was a Miss Shore, sister of the 'Sergeant-trumpet' of England. After their marriage, about 1693, she went on the stage, but did not attain to any great eminence.

Cibrario, LUIGI, an Italian historian and politician, was born at Turin, 23d February 1802. He studied law, entered the service of the state, and soon distinguished himself by his historical investigations. In 1848, when Italy rose against the Austrians, Charles Albert appointed him commissioner at Venice and a senator of Sardinia. In 1839 he published his *Della Economia Politica del Medio Evo*; in 1840, his *Storia della Monarchia di Savoia*; and in 1847, his *Storia di Torino*. In 1852 he was made Minister of Public Instruction, and ultimately, in 1855, Minister of Foreign Affairs. He published numerous other works on history, numismatics, and miscellaneous subjects. He died 1st October 1870. See the Life by Odovici (1873).

Cicada, a large genus of hemipterous insects, typical of the sub-order Homoptera, with uniform wings. They are well known for the noise made

Cicada.

by the males, and for the 'Manna' (q.v.) or sap which their incisions cause to exude from trees. Specially abundant in warm countries, some eighteen species of cicada occur in the vine-bearing regions of Europe. When they do occur, their presence is not kept secret, for in the warm sunshine the males keep up a continuous and very loud, doubtless amatory, chirping. Their shrill 'song' has been echoed by poets from Anacreon to Byron, but seems to have sounded more sweetly in the ears of the ancients.

Yet some people are so fond of the chirping that they keep the cicadas in little cages. Some large South American species are said to chirp 'loud enough to be heard at the distance of a mile.' The noise is caused by the vibrations of membranes at the openings of two respiratory tubes (tracheæ) on the last joint of the thorax, and the volume of sound is increased by two complex resonating cavities a little farther back. The apparatus is rudimentary in the females; which in this case at least cannot be blamed for noise. The commonest South European species is *Cicada orni*, feeding especially on ash-trees. *C. plebeia* is a somewhat larger form. *C. mannifera* causes abundant 'manna' in Brazil. *C. septendecim* is the North American 'seventeen years' locust,' or harvest-fly, said to occur in special abundance every seventeen years; though they probably appear in some part of the country every year. The males of the species perform the act of reproduction and soon die, probably taking no nourishment in the perfect state. The females deposit about 500 eggs in the twigs of trees, and die immediately after. The larvæ drop and bore their way into the ground, where they are supposed to remain for seventeen years, sucking the juices of the roots of trees and plants. There is also a thirteen years' variety or brood. When the pupæ emerge, the ground sometimes seems honeycombed by their numbers. The larvæ are devoured in great quantities by birds, frogs, and swine. The damage done by the larvæ in their long underground career is nothing as compared with that inflicted on the foliage by the perfect insect (female) during its short life. See Bulletin

No. 8 (1885) of the United States Department of Agriculture. *C. hematodes*, a small species, is recorded from the New Forest in Hampshire. The family to which the cicadas belong is often known as that of the *stridulant* insects, and includes about five hundred species. An even larger closely allied family is that of the Cicadellidæ, including the common Cuckoo Spit (q.v.). The name Cicada has sometimes been applied to another hemipterous insect, a common bug named *Halticus pallicornis* or *C. aptera* of Linneus. It need hardly be said that the cicadas are not crickets, or locusts, or grasshoppers.

Cicatrization (Lat. *cicatrix*, 'a scar'), the process of healing or skinning over of an ulcer or broken surface in the skin or in a mucous membrane, by which a fibrous material of a dense resisting character, covered by a protecting layer of epithelium, is substituted for the lost texture. The new tissue in such a case is called the cicatrix, and usually resembles to a considerable extent the structure which it replaces; it is, however, less elastic, and from its shrinking in volume may produce an appearance of puckering. This shrinking sometimes leads to serious results, especially after extensive Burns (q.v.). The glands and other special structures of the original tissue are wanting in the cicatrix, which, however, performs perfectly well, in most instances, the office of protection to the parts below the surface. See INFLAMMATION and ULCERATION.

Cicely (*Myrrhis*). See under CHERVIL.

Cicer. See CHICK PEA.

Cicero, MARCUS TULLIUS, 106-43 B.C., the foremost orator of ancient Rome, one of her leading statesmen, and the most brilliant and accomplished of her men of letters, lived in those stirring later days of the Roman republic, that age of revolution and civil wars, in which an old and decaying order of things was passing away. It was the age of great and daring spirits, of Catiline, Cæsar, Pompey, Antony, with whose history Cicero's life is closely intertwined. Born 106 B.C. at an old Italian town, Arpinum in Latium, of a good family, and inheriting from his father, who was a man of considerable culture, a moderate estate, he went as a boy to Rome, and there, under the best teachers and professors, he learned law and oratory, Greek philosophy, and Greek literature, acquiring in fact the universal knowledge which he himself says in his essay 'on the orator' (*De Oratore*) an orator ought to possess. An orator in the ancient world, we should bear in mind, was first and chiefly a pleader of causes, causes both legal and political—a speaker alike, as we should say, at the bar and in parliament. Hence the necessity for knowledge and information of every kind. Cicero's first important speech, in his twenty-sixth year, was the successful defence in a criminal trial of a client against one of the favourites of the all-powerful Sulla, then dictator. After a visit to Athens, and a tour in Asia Minor, where he profited by the society of eminent professors of rhetoric and men of letters, he returned to Rome, and at thirty years of age he was in the highest repute at the Roman bar.

In 76 B.C., having been elected quæstor (a financial secretary, as we may say) by a unanimous popular vote, he held an appointment in Sicily, where he won the good opinion of two highly important interests, apt at times to conflict, the traders and the revenue collectors. To this he owed the glory of his successful impeachment of the infamous Verres in 70 B.C., which he undertook at the request of the Sicilian provincials. The bad man who had so hideously misgoverned them felt himself crushed by Cicero's opening speech, and went into

voluntary exile. Cicero was now a power in the state, and his rise up the official ladder was sure and rapid: in 66 B.C. he was praetor, and supported in a great political speech (*Pro Lege Manilia*) the appointment of Pompey to the conduct of the war with Mithridates, which in fact carried with it the supreme control of Asia and of the East. In 63 B.C., at the age of forty-four, he was consul, the highest dignity attainable to a Roman; in that memorable year he foiled, by a bold promptitude, the revolutionary plot of Catiline, in which many distinguished Romans—Caesar, it was even said, among them—were implicated. He was now at the height of his fame; 'father of his country' he was actually called; for a brief space he was with all classes the great man of the day. But the tide soon turned; Cicero might have saved the country, but in saving it, it was said, he had violated the constitution, according to which a Roman citizen could not be capitally punished but by the sentence of the people in regular assembly. As it was, Roman citizens guilty of complicity with Catiline had, at Cicero's instigation, been put to death simply by an order of the senate; this, it was said, was a dangerous precedent, and Cicero must be held responsible for it. His bitter enemy, Clodius, now tribune, pressed the charge against him in inflammatory speeches specially addressed to the lowest class of citizens, and Cicero in despair left Rome in 58 B.C., and took refuge at Thessalonica. That same year saw 'the father of his country' condemned to exile by a vote of the Roman people, and his house at Rome and his country houses at Formiae and Tusculum plundered and ruined.

But in those revolutionary days the events of one year were reversed by those of the next; in 57 B.C., with new consuls and new tribunes, the people almost unanimously voted the recall of the exile, and Cicero was welcomed back to Rome amid an outburst of popular enthusiasm. But he was no longer a power in the world of politics; he could not see his way clearly; and he was so nervously sensitive to the fluctuations of public opinion that he could not decide between Pompey and the aristocracy on one hand, and Caesar and the new democracy on the other. His leanings had hitherto been towards Pompey and the senate and the old republic; but as time went on he felt that Pompey was a half-hearted man, who could not be trusted, and that he would have ultimately succumbed to his far abler and more far-sighted rival, Caesar. The result was that he lost the esteem of both parties, and came to be regarded as a mere trimmer and time-server. There was all that political indecision about him which may be often observed in eminent lawyers and men of letters. The age wanted strong men such as Caesar; this Cicero certainly was not. He was gentle, amiable, very clever, and highly cultivated, but the last man in the world to succeed in politics.

The later years of his life were spent chiefly in pleading at the bar and in writing essays. In 52 B.C. he composed one of his finest speeches in defence of Milo, who had killed Clodius in a riot, and was then standing for the consulship; in this he was acting quite against the wishes of Pompey. In the following year (51–50 B.C.) he was in Asia, as governor of the province of Cilicia, and here the best side of his character showed itself in his just and sympathetic treatment of the provincials. In 49–48 B.C. he was with Pompey's army in Greece to fight for the old cause, of which, however, he well-nigh despaired, and after the decisive battle of Pharsalia, at which he was not present, he threw himself on the conqueror's mercy. Caesar, who had certainly nothing to fear from him, received him kindly, and was a great friend to him from that day; but Cicero was not a happy man now that

he could no longer make speeches in the senate or in the courts; to all this Caesar's victory had for the time at least put an end. In the years 46, 45, and 44 B.C. he wrote most of his chief works on rhetoric and philosophy, living in retirement and brooding mournfully over his griefs and disappointments. In 43 B.C., the year after Caesar's death, he had once again the delight of having his eloquence applauded by the senate. In that year his famous speeches against Antony—Philippics, as he called them after the title of Demosthenes' orations against Philip of Macedon—were delivered. These cost him his life. As soon as Antony, Octavius (afterwards the emperor Augustus), and Lepidus had leagued themselves together in the so-called triumvirate for the settlement of the state, they followed the precedent of former revolutions and published a proscription-list of their political enemies. All such were outlawed and given up to destruction. Cicero's name was in the fatal list. Old and feeble, he fled to his villa at Formiae, pursued by the soldiers of Antony, and was overtaken by them as he was being carried in a litter down to the shore, where it had been his intention to embark. With a calm courage, which (to quote Macaulay's words) 'has half redeemed his fame,' he put his head out of the litter and bade the murderers strike. He died in the December of 43 B.C., in the sixty-third year of his age.

As an orator and a pleader Cicero undoubtedly stands in the first rank. Many of his speeches have come down to us. Of these the most famous and perhaps the finest are his speeches against Verres and against Catiline. Eloquence in those days of furious faction and revolution was a greater force than it is with us. As a politician he failed because he did not distinctly realise to himself that the old republic, the government of the senate and of the nobles, had been tried and had been found wanting. He had not the courage to face the great changes which he felt were impending. Pompey, the champion of the old order, was not a leader to whom he could look up with confidence. And so he wavered, and half acquiesced in Caesar's triumph, even though he suspected that with that triumph the Rome which he had known and loved would pass away. To us it is as an essayist and as the writer of a multitude of letters to friends, full of miscellaneous information, that Cicero is particularly attractive; there is a gracefulness and refinement and elevation of tone about his writings which cannot fail to incline the reader to say with Erasmus, 'I feel a better man for reading Cicero.' His essays on 'old age,' and 'on friendship,' his *De Officiis* or 'whole duty of man,' as we may paraphrase it, are good and pleasant reading such as we can all enjoy; and his more abstruse writings on philosophy, his Tusculan disputations, his treatises on the 'nature of the gods,' and on the 'true ends of human life' (*De Finibus*), if they do not show any very deep and original thought, at least give us an insight into the teachings of the various ancient philosophical schools.

The best edition of Cicero's works is that of Baiter and Kayser (1869); the best lexicon thereto, Merguet's (Jena, 1877–84). See also the *Lives* by Middleton (1741), Forsyth (1864), Jeans (1880), Trollope (1880); also *Cicero*, in *Ancient Classics for English Readers*, by Lucas Collins (new ed.).

Cicero-né (from Cicero, 'the orator' or 'speaker'), a name given by the Italians to the guides who show travellers the antiquities of the country. Cicerones are to be found of all degrees of knowledge or respectability, from distinguished local archaeologists to the humble *laquais de place*, who, though quite indispensable on a first arrival, is too often both incompetent and dishonest.

Cicho-r'ium. See CHICORY and ENDIVE.

Cicindella, a genus of beetles in the section Pentamera, and type of a family with some 300 species. They are very active, and occur abundantly on sandy places. *C. campestris* is a common British species of a green colour.

Cicisbeo, a professed gallant who waits with fantastic devotion upon a married lady. In the higher ranks of Italian society it was at one time considered unfashionable for the husband to associate with his wife anywhere except in his own house; and in society, or at public places of amusement, the wife was accompanied by her cicisbeo. Cicisbeo is synonymous with *cavaliere servente*.

Cicu'ta. See HEMLOCK.

Cidaris, a genus of Sea-urchins (q.v.), and type of a family (Cidaridae) with very long spines. The most of the members of the family are fossil forms, but over a score of living species are known. *Dorocidaris papillata* is occasionally dredged to the north of Scotland, and its beautifully marked spines in some instances measure over six inches in length, being often twice as long as the cross diameter of the shell. It is sometimes popularly called the *Piper* from a fanciful resemblance to bagpipes.

Cid Campeador, the name, or rather names, by which the most renowned Spanish warrior of the 11th century is best known. By his Moorish vassals he was called 'Sid-i' ('my lord'), which the Spaniards translated by Mio Cid, and a victory in his youth over a Navarrese champion in single combat gave him the title of Campeador. His real name was Rodrigo, or Ruy, Diaz (i.e. 'son of Diego'). He was a Castilian noble by birth, seventh in descent from Nufio Rasura, who was also ancestor of the royal line of Castile. He was born either at Burgos or at Bivar near it, about the year 1040. From 1065 to 1072 he was nominally alférez, or 'ancient,' but virtually commander of the forces to Sancho II. of Castile in the wars in which that king wrested the kingdoms of Leon and Galicia from his brothers. In 1072 Sancho was treacherously slain at the siege of Zamora, and as he left no heir the Castilians had to acknowledge Alfonso, the banished king of Leon. As a conciliatory measure Alfonso gave his cousin Ximena, daughter of the count of Oviedo, to the Cid in marriage, but afterwards, in 1081, when he found himself seated on the throne, yielding to his own feelings of resentment, and incited by the Leonese nobles, he banished him from the kingdom. According to tradition he never forgave the Cid for having, as leader of the Castilians, compelled him to swear that he had no hand in the murder of his brother Sancho, but there is no need to look for any cause beyond the hereditary animosity between the Castilians and the Leonese, now intensified in the latter by recent defeat and humiliation, for which they held the Cid responsible. At the head of a large body of followers the Cid betook himself to Muctadir of the Beni Hud, the so-called king of Saragossa, to whom, and to his son and grandson, he rendered important services against their enemies the king of Aragon and the count of Barcelona. In conjunction with Mostain, grandson of Muctadir, he invaded Valencia in 1088, but afterwards carried on operations on his own account, and finally, after a long siege, made himself master of the city in June 1094. The Almoravides, then in possession of south and central Spain, twice sent large armies against him, but were each time routed with great loss. For five years he reigned like an independent sovereign over the fairest and richest territory in the Peninsula, but in July 1099 he died suddenly, of grief, the Arabic annals say, at the news that some of his men had been defeated. His widow held out for two years longer, and then retired, carrying with

her the embalmed body of the Cid, which for ten years sat enthroned beside the high altar at San Pedro de Cardena, near Burgos.

The Cid's career cannot be better summed up than in the words of a contemporary and an enemy, Ibn Bassam of Seville, who wrote only ten years after his death, and could cite the testimony of one who knew him and was an eye-witness of his deeds in Valencia. Of the Cid—whom he calls 'a Galician dog, one Roderic, surnamed the Canbitur, the scourge of the country'—he says: 'It was the Beni Hud who raised him out of obscurity, and they delivered over to him divers provinces of the Peninsula, so that he overran the plains like a conqueror, and planted his banner in the fairest cities.' His power grew very great, nor was there any district that he did not ravage. Nevertheless this man, the scourge of his time, was, in his love of glory, strength of character, and heroic courage, one of the marvels of the Lord. Victory always followed his banner—God's curse be on him.' The character of the Cid was, however, a somewhat complex one. There can be no doubt of his cruelty, rapacity, and duplicity, for the statements of the Moorish authorities are substantially confirmed by the Spanish, the *Cronicas*, the *Gesta Roderici Campidocti*, and even the *Poema* itself. But it may be said for him that to strike terror was one of the necessities of his position, outnumbered as he was by a hundred to one; and had he not made plunder his prime object the army he led would soon have melted away. Unscrupulous *condottiere* as he was, fighting for paymaster or plunder, he was nevertheless a staunch patriot at heart. Ibn Bassam had it from one who heard him that he said: 'This peninsula was conquered under one Roderic, but another Roderic shall deliver it.' He was an imperfect hero; but he was a born leader of men, and it was only natural that a career like his should take a strong hold of the popular imagination, and in an age when minstrelsy flourished become a favourite theme with the jongleurs and trovadores. These, when facts began to run short, met the demand by drawing upon their invention, and treated the Cid precisely as they treated Charlemagne. As they invented the journey to Jerusalem, the expedition to Galicia, the Bridge of Mantible, and the Emir Balan for Charlemagne, so they devised an invasion of France for the Cid, made him defy the emperor Henry, beard the pope, cut off the head of the count of Gormaz and marry his daughter; and to allow time for all, they put back his birth twenty years, and even extended the life of his charger Baveca to sixty. They also married his daughters to the Infantes of Carrion, princes of the blood-royal of Leon. Historically, the Cid's daughters were married, one to a count of Barcelona, the other to a prince of Navarre, a union by which his blood passed into the royal line of Castile, and thence into the Bourbon, Hapsburg, and our own royal families. Alfonso X. adopted all the amplifications of the minstrels in the *Cronica General*, from which they found their way almost unquestioned into the history of Spain; and their inconsistencies and absurdities have in some instances led uncritical and somewhat indolent historians like Masdeu and Dr Dunham to treat the whole story of the Cid as a fable, and himself as no better than a creature of popular fancy.

Of the Cid literature it is impossible to give more than a summary here. By far the most important in every way of the works belonging to it is the *Poem*, written undoubtedly in the last half of the 12th century, and probably the oldest document in the Spanish language. It is more properly an epic than a *chanson de geste*, and unquestionably the most Homeric piece of medieval poetry in existence.

Editions of it have been given by Janer and Pidal in the *Biblioteca de Autores Españoles* (vol. lvii.), by Vollmöller, with introduction and notes, and by Damas Hinard, with a French prose translation. It has been translated into German by O. L. B. Wolff, and there is an English translation with introduction and notes by John Ormsby. The translated fragments by J. H. Frere do little justice to the dignity, sense, and spirit of the old Spanish poem. The *Cronica Rimada*, a very inferior work of a much later date, deals mainly with the apocryphal invasion of France. The prose *Cronica del Cid* (Burgos, 1512) is merely that part of the *Cronica General* which refers to the Cid, with some additions and corrections. Southey's admirable *Chronicle of the Cid* is a composite work made up of portions of the *Cronica* and of the Poem, skilfully interwoven so as to give the story of the Cid as the old story-tellers told it. Risco's *Castilla* (1792) contains, besides a life of the Cid, the original Latin text of his marriage-settlement, dated 1074, the Santiago Genealogy, and the *Gesta Roderici Campidocti*; both written before 1238. Of more modern works the most notable are Malo de Molina's *Rodrigo el Campeador* (1857) and Professor Dozy's *Le Cid d'après de nouveaux Documents* (1860), with copious extracts from the *Dhakhira* of Ibn Bassam. The Cid ballads, so numerous in the old *cancioneros* and *romanceros*, were collected and printed in a *romancero* by themselves by Escobar in 1612. The fullest and best *romancero del Cid* is that of Carolina Michaelis (1872), which contains no less than 205 ballads. Only a few, however, of the Cid ballads are of high excellence, or to be regarded as specimens of genuine traditional popular poetry. The greater number are comparatively modern, many are merely portions of the *Chronicles* put into verse, and not a few are artificial ballad imitations of the 16th and 17th centuries.

Cider, or **CYDER**, is the fermented juice of apples, and is extensively prepared in Devonshire, Herefordshire, Gloucestershire, and other parts of England, in the United States, and in the northern districts of France and Germany. The apples commonly used for making cider are by no means tempting to the palate, are in fact unfit either for eating raw or ordinary cooking. Three kinds may be used—viz. the bitter, the sweet, and the sour; but the first are generally preferred, and are specially cultivated in the cider orchards. These bitter apples contain a considerable amount of sugar, but it is masked to the palate by the extractive matter also present. Late apples afford much better cider than early ones. The apples after gathering are left for some days to mellow or mature. This has the further advantage of showing the unsound apples, which are rejected, as giving the whole an incurably musty flavour. In the United States it is considered that a certain proportion of decaying fruit improves the flavour; probably they act by hastening or modifying the fermentation. The apples are crushed by passing them between fluted rollers, or in mills of various kinds. Some improved cider-mills grind the fruit to a perfectly homogeneous pulp. These mills give an increase in quantity, with a falling-off in quality of the product. The pulp thus obtained is placed in tubs or vats with or without a little water, and left for about a day. During this time fermentation commences and assists in breaking up the cells of the pulp. Or the pulp is more completely broken up at once. The pulp is next placed in coarse canvas or haircloth bags, or on a wicker-work or perforated frame for the juice to drain into a tub or vat. This juice is reserved for the best quality of cider. The remaining juice is removed by squeezing the bags and their contents in a press. The old process of laying up the pulp or pomace in

straw for pressure gives a good quality of juice. The greater the pressure, the coarser the flavour, due to that of the pips and skins, but of course the quantity is increased by additional pressure.

The next process is the full fermentation. This is usually effected in casks with large bung-holes. The casks being filled with juice, much of it froths over during fermentation, and therefore the casks are placed over open tubs which catch it. Care is necessary to keep the casks full, so that the excess of yeast may thus be continually removed, such excess promoting acetic fermentation. This is continued from three to eight or ten days according to the alcoholic strength required. It is then racked off from the sediment into clean casks and stored in a cellar or other place with cool and equable temperature. In the following spring this racked cider is re-racked, and is then ready for use or sale.

A weaker cider, used as a common beverage for farm labourers, is made by adding about half its weight of water to the marc or pressed pulp and fermenting this as above. The refuse pulp or 'apple cheese' is used as food for pigs and cattle.

Cider contains from 4 to 10 per cent. of absolute alcohol—i.e. 8 to 20 per cent. of proof spirit, according to quality. This depends upon the quantity of sugar originally in the juice, and upon the care in fermentation, especially in respect to temperature, which should be about 50° F. This is too commonly neglected, and the fermentation left to the accidents of weather. Much acetic acid is thus formed when the autumn is warm, rendering the cider rough. Sweet cider is that in which only a small proportion of the sugar has been converted by fermentation into alcohol or acetic acid. The best cider is mellow and vinous, neither sweet nor acid. The bottling of cider demands much care. Only clear samples are fit for bottling, and they should be at least twelve months old and free from hardness or acidity. Good mellow or slightly sweet cider carefully bottled before fermentation is fully completed constitutes champagne cider, and is used as a basis of factitious champagne.

Cienfuegos, a port of Cuba, on the south coast, on the Bahía de Jagua, 140 miles ESE. of Havana, with which, as with all the north-west of the island, it has railway communication. In 1887, 232 vessels, of 217,338 tons, cleared the port. The exports amounted to £1,038,827, chiefly sugar, molasses, rum, and wax. Pop. (acc. to British consul, 1888) 65,556.

Cieza, a town of Spain, 26 miles NW. of Murcia. Pop. (1877) 10,910.

Cigars and Cigarettes. See TOBACCO.

Cigoli (properly LUDOVICO CARDI), a painter of the later Florentine school, was born at Cigoli, near Florence, in 1559. His models were Andrea del Sarto and Correggio; but he has his own style, marked by expression and fine colour. He was invited by Clement VII. to Rome, where he died in 1613. Cigoli was also held in high estimation as an architect.

Cilia (Lat., 'eyelashes'), hair-like lashes borne by cells. They are mobile modifications of the living matter of the cell, and exhibit alternate bending and straightening. Their occurrence is very wide—e.g. on the active stages of many unicellular plants; in great perfection on the ciliated Infusorians; on the free-swimming embryos of sponges, Coelenterates, worms, echinoderms, and molluscs; on the outer surface of many lower animals such as simple worms; on the lining of the alimentary cavity, and in most of the tubular organs of Invertebrates; and more restrictedly, though not less markedly, in some regions (such as trachea) of higher forms. They are absent throughout the Arthropods (with one possible exception), a fact

probably to be associated with the predominance of Chitin (q.v.). In many cases, normal, pathological, and artificial cilia may sink down into less motile amoeboid processes. A single lash with an undulating movement is distinguished as a *flagellum*; and Ray Lankester emphasises the useful distinction between a *flagellum* such as that of a bacterium, or the tail of a spermatozoon, which acts 'like a tadpole's tail' and drives the cell before it, and the motive process of a flagellate Infusorian which carries the cell behind it. See CELL.

Cilicia, an ancient division of Asia Minor, now included in the Turkish province of Adana, which lay between the Taurus range and the Cilician Sea, while the Amanus range separated it from Syria. The eastern portion of Cilicia was fertile in grain, wine, &c.; the western and more mountainous portion furnished inexhaustible supplies of timber to the ancients. The pass called by the Turks (Gölek Boghaz) (anciently *Pylæ Ciliciæ*) is that by which Alexander the Great entered Cilicia. In early ages Cilicia was ruled by its own kings, the people, who were probably akin to Syrians and Phœnicians, being notorious pirates. The country fell successively under Persian, Macedonian, and Syrian rule, and was made a Roman province by Pompey in 67 B.C. See ASIA MINOR.

Cimabué, GIOVANNI, the first of the restorers of the art of painting in Italy, which had fallen into neglect during the barbarism of the dark ages, was born at Florence in 1240. At this time the fine arts were practised in Italy chiefly by Byzantines, though there were such native artists as Guido di Siena and Giunto of Pisa; and painting had degenerated into a worn-out mechanical conventionalism. Cimabue at first adopted traditional forms, but he soon turned to nature, painting a St Francis from the living model, 'a new thing in these times,' as Vasari tells us, infusing life and individuality into the worn-out types of his predecessors, and leading the way to the naturalism of the works of his great pupil Giotto (q.v.). In the stiff forms of his draperies he made little progress upon former practice, but he softened his outlines, improved his flesh-tints, and gave projection and a sense of rotundity to his forms. Two remarkable pictures of the Madonna by Cimabue are still preserved in Florence—one in the Academy; the other, displaying a more purely original genius, in the church of Santa Maria Novella. It is said that this latter work in the time of Cimabue was admired as a miracle of art, and was carried to the church in a sort of triumphal procession. It is the first great production of the Florentine school which culminated in Michael Angelo, Raphael, and Leonardo. Cimabue executed several important frescoes in the south transept of the lower church of San Francesco at Assisi, and in the north transept of the upper church there; and during his later years he was appointed *capo maestro* of the mosaics of the Duomo of Pisa, his works in this method ranking as the finest of the period. His mosaic of Christ in glory in the apse was probably his last work; and his easel-picture of a Madonna and Child in the Louvre was executed for San Francesco at Pisa. He died about 1302.

Cimarosa, DOMENICO, an Italian composer of operas, was born either at Aversa, 17th December 1749, or more probably at Naples in 1755. He was certainly educated at Naples, in music under Sacchini, and in the conservatory of Loretto. His first pieces were the *Sacrificio di Abramo* and the *Olympiade*. When barely twenty-two he had achieved a reputation in all the leading Italian theatres. He was then called to St Petersburg as composer to the Empress Catharine II., where he resided four years. Afterwards he lived at various

German courts; thence he proceeded to Vienna, where he became imperial *kopellmeister*; and finally he returned to Italy. At Naples, his comic opera, *Il Matrimonio Segreto*, composed at Vienna, 1791, was repeated seventy times in succession. Cimarosa died at Venice, 11th January 1801. His comic operas are remarkable for their novelty, spirit, whimsicality, and liveliness of idea, as well as for their great knowledge of stage-effect.

Cimbri, or KIMBRI, a people who issued from the north of Germany in conjunction with the Teutones, and first came into hostile contact with the Romans in the province of Noricum (Carinthia and Carniola) in 113 B.C. They were victorious in several great engagements, and were only prevented from devastating Italy by a terrible defeat they suffered from Marius on the Raudii Campi, near Verona, or, according to others, near Vercelli, in August 101 B.C. They fought with desperate courage, and when the battle was lost, their women killed themselves and their children; It is not till long afterwards, when the Romans themselves penetrated into Germany, that the name of the Cimbri again appears. Caesar represents the Aduatici of Belgium as the descendants of the Cimbri and Teutones. Tacitus speaks of a people bearing the name of Cimbri, few in number, but of great reputation, that sent ambassadors to Augustus. This people lived in the extreme north of Germany, on the borders of the ocean; according to Pliny and Ptolemy, at the extremity of the peninsula called from them the Cimbric Chersonese, now Jütland. The ethnology of the Cimbri is doubtful. Greek writers associated them groundlessly with the Cimmerians; Sallust calls them Gauls; Caesar, Tacitus, Plutarch, and most moderns look upon them as Germans. Some, however, have maintained that they were Celtic, and have tried to fortify their argument by a desperate analogy with the name *Cymry*.

Cimex. See BUG.

Cimmerians, or CIMMERII, in Homer, a legendary people dwelling 'beyond the ocean-stream, where the sun never shines, and perpetual darkness reigns.' The name was also applied to a fabulous people who dwelt in caves between Baie and Cumæ. Hence the common phrase, 'Cimmerian darkness.' The historic Cimmerii were a people whose country lay between the Borysthenes (Dnieper) and the Tanais (Don), including also the Tauric Chersonesus (Crimea). The Cimmerian Bosphorus (Strait of Yenikale) derived its name from them. Being driven out by the Scythians, they migrated to Asia Minor, dwelt there for some time, plundered Sardis, failed in an attempt upon Miletum, and were finally routed and expelled by the Lydian king Alyattes, some time after 617 B.C.

Cimolite. See FULLERS' EARTH.

Cimon, an Athenian commander, was the son of the great Miltiades, the conqueror at Marathon. Being unable to pay the fine of 50 talents from which his father escaped by dying, he was kept in prison until the fine was paid by the wealthy Callias who had married his sister. Young Cimon enjoyed the patronage of Aristides, and soon distinguished himself in the patriotic struggle against the Persians. In conjunction with Aristides he was placed over the Athenian contingent to the allied fleet, which, under the supreme command of the Spartan Pausanias, continued the war against the Persians (477 B.C.). He effected the important conquest of Eion, a town on the river Strymon, then garrisoned by the Persians. His greatest exploit was his encounter with a Persian fleet of 350 ships at the river Eurymedon (466), when he destroyed or captured 300, and defeated the land-

forces on the same day. He succeeded likewise in driving the Persians from Thrace, Caria, and Lycia; and expended much of the money which he had obtained by the recovery of his patrimony in Thrace upon the improvement of the city of Athens. The lavish bounty with which he opened his gardens and the honours of his table, together with his cheerful temper and patience, endeared him to his fellow-citizens. At this period he appears to have been the most influential of the Athenians. The hereditary enemy of Persia, it was his policy to advocate a close alliance with Sparta; and when the Helots revolted, he twice led an army to the support of the Spartan troops; but on the latter occasion, having lost the confidence of his allies, he was ignominiously dismissed. After his return to Athens his policy was opposed by the democracy, headed by Pericles, who procured his banishment by ostracism. He was recalled in the fifth year of his exile, and was instrumental in obtaining a five years' armistice between the Spartans and the Athenians. He died in the year 449 B.C., at the siege of a Cyprian town.

Cincho'na (properly CHINCHONA), a most important genus of trees of the order Rubiaceæ (sub-order Cinchonaceæ), yielding the bark so much valued in medicine, which has been variously known as Peruvian Bark, Jesuit's Bark, China Bark, Quina, Quinquina, Cinchona Bark, &c., and from which the important alkaloids quinine and its congeners are obtained. The species of this genus are sometimes trees of great magnitude; but an aftergrowth springing from their roots when they have been felled, they often appear only as large shrubs; and some of them in the highest mountain-regions in which they are found are low trees with stems only 8 or 10 feet in height. They are natives of South America between 20° S. lat. and 10° N. lat., and chiefly on the eastern slope of the Cordilleras. The best cinchona formerly came from the province of Loxa in Ecuador. The range of altitude of course diminishes as we recede from the equator, but may be averaged at from 8000 to 5000 feet for the best varieties. The climate of these regions is extremely variable, and this seems to have more effect upon the trees and their product than differences in soil. All the cinchonas are evergreen trees, with laurel-like, entire, opposite leaves; stipules which soon fall off; and panicles of flowers, which, in general appearance, are not unlike those of lilac or privet. The flowers are white, rose-coloured, or purplish, and very fragrant.

Such difficulty has been found in determining the species of cinchona and the different varieties of bark known in commerce that a voluminous special literature of 'quinology' has been called into existence. This difficulty is due partly to the large number and great variability of the species, and even of individual specimens of bark, as also to the difficulty of obtaining specimens of flowers and leaves along with particular kinds of bark. The most important species are *C. officinalis* of Ecuador and Peru, *C. Calisaya* of Bolivia and south-east Peru, and *C. succirubra* of the western slope of Chimborazo; but others (Carthagena Bark, Columbian Bark, &c.) are also of importance, while the varieties are too numerous to mention. The barks of allied species which, although more or less bitter and even febrifugal, contain no quinine are apt to be used as substitutes or adulterations.

The cutting and peeling of cinchona-trees is a laborious and difficult operation carried on by Indians during the dry season. They build a hut, which serves both for their abode and for drying the bark. The trees are felled as near the root as possible, that none of the bark may be lost; and the bark being stripped off, is carefully

dried and packed; the quilled form of the thinner bark is acquired in drying.

This wasteful and costly mode of collection from almost impassable forests, in which, moreover, the

Cinchona lancifolia.

tree was becoming exterminated, and this in face of an increasing demand, gradually roused the attention of European botanists to the desirability of inaugurating a regular culture in similar regions and climates of the Old World; but the successful introduction of cinchona-seeds into Europe was only effected by Weddell in 1848, and his seedlings were sent from the Jardin des Plantes to Algiers in 1850, and to Java in 1852. The Dutch government also imported a few living plants from Peru in 1854. The credit of really solving the difficult problem of acclimatisation is, however, due to Mr Clements R. Markham. Himself going to Peru and Bolivia for *C. Calisaya*, he secured the services of Spruce, a well-known collector then resident in Ecuador (who was similarly successful in obtaining *C. succirubra*), as well as those of three other effective conjutors. The expedition was attended by much difficulty and danger, and its narrative has a prominent place in the history of botanical travel. Plantations were formed in the Neigherry Hills, and thence spread to Sikkim at the foot of the Himalayas, to British Burma, Ceylon, &c. Cinchona is also being grown in the West Indies, and its acclimatisation in all suitable localities continues to make progress and to become an important industry.

The Indians of Peru call the cinchona-trees *Kina*, from whence are derived the names *Quina*, *China*, &c. But there is no evidence that they knew the use of the bark before the arrival of the Spaniards, nor will they even yet employ it in their native medicine. It was first imported into Europe in 1639, by the Countess of Chinchon, the wife of the viceroy of Peru, who had been cured of an obstinate intermittent fever by means of it, and who thereafter habitually distributed it to those suffering from fever. Upon this account it was named *C. Bark* and *Countess's Powder* (*Pulvis comitisæ*). The Jesuit missionaries afterwards carried it to Rome, and distributed it through their several stations, and thus it acquired the name of *Jesuits' Bark* and *Pulvis patrum*. Cardinal Juan de Lugo having been particularly active in recommending and distributing it, it was also known as *Cardinal de Lugo's Powder*. It attained great celebrity in Spain and Italy, being at first distributed to the poor, but later sold at high prices by

the Jesuits, by whom it was lauded as an infallible remedy, while by most of the orthodox physicians it was coldly received, and by the Protestants altogether repudiated. Falling thus into practical disuse in Europe, it was again brought into notice by Robert Talbot or Talbot, an English apothecary, who acquired great celebrity through the cure of intermittents by its use. In 1678 he was appointed physician in ordinary and knighted by Charles II., whom he next year cured of a tertian fever. In 1679 he similarly cured the Dauphin and other eminent personages on the Continent, and thus induced Louis XIV. to purchase his secret. The adoption of the drug was henceforth assured, despite the exceeding jealousy of the profession in England and France of both the success and fortune of the irregular practitioner, who did not, however, live much longer to enjoy his reward. The Parisian faculty of medicine held out bravely, a corroboration, if any were needed, of Molière's account of them, but the example and authority of Morton and Sydenham at length gained respectability to the side of science. As it came into general use, it became a most important article of export from Peru; and in order to the maintenance of a commercial monopoly, although no attention was ever paid to its culture, extraordinary methods were employed to prevent it from becoming known at a comparatively recent period of Spanish rule in America. The discovery of the alkaloids on which its properties chiefly depend constitutes a new era in the history of this medicine, and did not take place till the beginning of the present century.

The account of these alkaloids and their physiological and therapeutical action will be found under Quinine (q.v.). An excellent outline of the whole subject, with introduction to the literature of quinology, is to be found in Plücker and Hanbury's well-known *Pharmacographia*, and in most manuals of pharmacology. In Markham's *Peruvian Bark* (1880) will be found almost all matters of general interest; and there is a *Handbook of Cinchona Culture*, by Van Gorkhom (trans. by Jackson, 1882).

Cincinnati, the largest city of Ohio, U.S., stands on the north bank of the river Ohio, 270 miles S.E. of Chicago by rail, opposite the cities of Covington and Newport, in Kentucky, and the smaller towns of Dayton, Bellevue, and Ludlow. Steam-ferries and lofty bridges connect the city with the Kentucky shore. Cincinnati occupies an exceedingly broken and irregular site, the more densely built parts being inclosed between the river and steep hills. This lower portion includes the principal business streets, for the most part wide and well finished; but the lowest level is devoted largely to warehouses and manufacturing establishments, and at high stages of water is sometimes liable to be flooded. A second terrace is 50 or 60 feet higher, and is densely occupied. A district between the hills and the Miami Canal is known as 'over the Rhine,' and is appropriated to the large German colony. But the most interesting portions of the city are the suburbs, which are singularly beautiful. They are built on a succession of irregular hills, by whose steepness the beautiful suburban district has been broken into a succession of comparatively isolated villages, interspersed with parks (of which Eden Park, of 206 acres, is the largest), and approached at various points by noble winding avenues. The principal way of access, however, is by inclined steam-railways and horse-cars, or in one instance, by wagon and passenger elevators. This suburban region, and in fact a considerable part of the south-western angle of the state, is of that geological epoch in which the highly characteristic rocks of the so-called 'Cincin-

nati group' were deposited. They are richly fossiliferous, and are the highest beds of what are known as the Lower Silurian rocks, corresponding nearly with the Upper Caradoc beds of British geologists. There are more than twenty-five such suburbs, most of them within the city limits; Clifton and Walnut Hills, the latter looking out over Kentucky, are especially striking, and Spring Grove has a fine cemetery of some 600 acres.

The city has an area of 24 sq. m., is well built and well drained, and the water-supply from the Ohio is ample. Among the principal public buildings are the post-office, an imposing structure; a massive and very admirable new Chamber of Commerce; a large art museum (unfinished); an art school, and a college of music (1878), of deservedly high repute; a large music-hall, with a noted grand organ; a commodious city building; and a court-house. There are more than 200 churches, several of them large and architecturally noteworthy, including a Roman Catholic cathedral; besides many handsome theatres, hotels, and public halls. The city has several ample hospitals and infirmaries (public and private), a large asylum for the insane, and many other institutions for charity and correction. There are public and private schools of every grade, among them three high schools, a normal school, a school of design, and a technical school. The fourteen professional schools include six medical schools, one school of law, and two of divinity, one of which (Lane Theological Seminary, Presbyterian) has a wide reputation. Cincinnati University is free to resident youths, and to it the Cincinnati Observatory and Astronomical School are affiliated. The city has several important libraries, one of which (the Free Public Library) contains some 150,000 bound volumes and 18,000 pamphlets. There is a Zoological Garden, and the Cuvier Club and the Historical and Philosophical Society possess considerable collections. Finally, Cincinnati is well known as a centre of musical and art culture, and its decorative pottery and wood-carving have a national reputation.

Besides its large river traffic, the city transacts a great amount of business by rail. A large number of railways converge to this place, and it is a receiving and distributing centre of great importance. The Miami and Erie Canal (1827), extending northward from Cincinnati (246 miles) to Toledo, is also the channel of a considerable trade. A very large proportion of Cincinnati's staples of trade are manufactured in the city, or its near vicinity. In 1872, 43,739 persons were employed in the manufactures, and the value of the goods produced was a little over \$100,000,000; in 1886 the labourers numbered 93,103, and the products were valued at \$190,722,153. Many steamboats and barges are built here. The city has sixteen banks, a clearing-house, a board of trade, a chamber of commerce and merchant's exchange, and other similar organisations. The condition of the labouring classes is in general very good. There are some 170 building associations, which greatly facilitate the ownership of houses by working-men. The book-trade is represented by several first-class and a number of minor publishing-houses. The slaughter-houses, stock-yards, and grain-elevators are very extensive.

Cincinnati was first settled by white men in 1780, and was permanently occupied in 1788. Its name was given in honour of the Society of the Cincinnati. It is believed that a portion of its site was occupied before the historic period by a considerable aboriginal population. Mounds containing various relics appear to confirm this opinion. It was incorporated as a city in 1819, and from its prosperity and attractiveness, it early attained the name of 'the queen city of the west.' The sobri-

quet of 'Porkopolis' commemorates its immense trade in pork and other hog products, which has now been largely diverted to other cities. The first steamboat reached Cincinnati in 1811, descending the river from Pittsburg; and the first railway from the city was opened in 1845. Its first Roman Catholic bishop was consecrated in 1822, and the see became archiepiscopal and metropolitan in 1850. In the same year the lower part of the city suffered much from a great flood. Cincinnati very early became prominent for its social culture, and for a long time it was almost the literary capital or headquarters of the whole region west of the Alleghanies. The unusual local development of a taste for the fine arts and for music was likewise noticeable at an early date, and is still a characteristic of the town. Great riots occurred in 1884, and were with difficulty suppressed by the military. Pop. (1800) 750; (1850) 115,436; (1870) 216,239; (1880) 255,139, of whom 8128 were coloured. In 1888 it was estimated at 325,000.

Cincinnati (the Cincinnatienses), a society or order in the United States of North America, established by the officers of the revolutionary army in 1783, 'to perpetuate their friendship, and to raise a fund for relieving the widows and orphans of those who had fallen during the war.' It was so named because it included patriots, headed by Washington, who in many instances had left rural affairs to serve their country (see CINCINNATUS). The badge of the society is a bald eagle suspended by a dark-blue ribbon with white borders, symbolising the union of France and America. On the breast of the eagle there is a figure of Cincinnati receiving the military ensigns from the senators, round the whole are the words, *Omnia reliquit servare rempublicam*. As this distinction was made hereditary, it was attacked as opposed to republican equality. Franklin saw in it the germ of a future aristocracy; and at a meeting held in Philadelphia in 1784 several changes were made in the constitution of the society, the right of succession being made conditional on approval in each case by the society. After 1804 the branches in several of the states were abolished. There are still, however, several state societies, which hold a general meeting by delegates triennially. See the *Memoirs of the Pennsylvania Historical Society*, vol. vi.

Cincinnati Epoch, the name given in North America to a subdivision of Silurian time.

Cincinna'tus, LUCIUS QUINCTIUS, a favourite hero of the old Roman republic, regarded by the later Romans as a pattern of antique virtue and simple manners. In 460 B.C. he was chosen consul, and two years later was made dictator. When the messengers from Rome came to tell Cincinnati of his new dignity they found him ploughing on his small farm. He soon rescued the consul Lucius Minucius, who had been defeated and surrounded by the Æqui, but Livy's account of the mode in which the deliverance was effected contains inconsistencies which did not escape the critical eye of Niebuhr. Sixteen days after, he laid down his dictatorship and returned to his small farm on the Tiber. At the age of eighty he was once more made dictator to deal with the alleged treasonable conspiracy of the great plebeian, Sp. Maelius.

Cinder-bed, a name given by the quarrymen to a stratum of the Middle Purbeck series of the Jurassic system, almost entirely composed of the loosely aggregated shells of a small oyster (*Ostrea distorta*).

Cineas, a Thessalian, the friend and minister of Pyrrhus (q.v.), was the most eloquent man of his time. Pyrrhus said his words had won him more cities than his own arms. He died about 270 B.C.

Cinera'ria, a large and widely distributed genus of annual or perennial herbaceous composites, very closely allied to Senecio (Groundsel, Ragwort, &c.), of which it is indeed often reckoned a sub-genus. Two small species are natives of the southern parts of Britain. The flowers of some are very pretty. *C. maritima*, from the Mediterranean shores, is a handsome garden perennial, and many Cinerarias are also grown in green-houses in Britain; these, however, are mostly florists' flowers produced by cultivation and hybridising. The most important parent plant of these is *C. cruenta*, a native of Teneriffe.

Cineraria cruenta.

Cinercary Urns. See URNS.

Cingalese. See CEYLON.

Cinna, LUCIUS CORNELIUS, a Roman patrician, one of the principal supporters of the faction of Marius. After Sulla had driven Marius from the city, and before setting out on his expedition against Mithridates, he allowed Cinna to be elected to the consulship on condition of his swearing not to disturb the constitution as then existing. No sooner, however, had he entered upon that office (87 B.C.) than he impeached Sulla, endeavoured to form an interest among the citizens who had been added to Rome after the Social War, and agitated for the recall of Marius (q.v.). Cinna and Marius next declared themselves consuls after a cruel massacre of the Roman citizens, in which some of the most eminent citizens were slain. On the death of Marius, which occurred within a few days of his usurpation, Cinna made L. Valerius Flaccus his colleague for that year, and C. Papirius Carbo for the two succeeding years. In 84 B.C. he prepared to meet Sulla, who was then on his way from the East to take vengeance upon his enemies, but was slain by his disaffected troops at Brundisium. During his fourth consulate his daughter Cornelia had been married to Julius Cæsar.

Cinnabar, an ore of mercury, from which almost all the mercury of commerce is obtained. Chemically it is a sulphide of mercury containing 86.2 parts of mercury and 13.8 of sulphur. It occurs both crystallised and massive, not unfrequently disseminated. Its crystals are six-sided prisms. It varies from perfectly opaque to almost transparent; has an adamantine, almost metallic lustre, and a carmine colour, with a bright scarlet streak. Its specific gravity is 8 to 8.2. *Hepatic Cinnabar*, so called from its liver-brown colour, is a variety containing a little carbon. Cinnabar sometimes occurs in primitive rocks, but more frequently in those of the coal formation. The cinnabar mines of Almaden, in Spain, have been worked for about 2300 years, and have been surpassed in productiveness by those of New Almaden in California. Cinnabar mines exist also in Idria, Germany, Hungary, Peru, China, and Japan. Cinnabar is used as a pigment under the name of *Vermilion*.

Cinnamic Acid. $C_6H_5CH = CHCOOH$, exists in the free state in the balsams of Tolu and Peru, in liquid storax, and in gum benzoin. When oil of cinnamon (see below) is exposed to the air, it absorbs oxygen and deposits crystals of cinnamic acid. Cinnamic acid forms colourless crystals readily soluble in alcohol, ether, and boiling water, but sparingly soluble in cold water. It is not of any importance in the arts, and is chiefly interesting as being the acid corresponding to oil of cinnamon. This oil is the aldehyde of cinnamic acid, and is represented by the formula $C_6H_5CH = CHCOH$. Although isomeric with oil of cassia, it has a slightly different flavour, and is much more expensive. Both of these oils are employed in medicine as aromatic stimulants, but chiefly as pleasant adjuncts to disguise the taste of nauseous drugs. From a chemical point of view, the cinnamic acid and oil of cinnamon are related to Benzoic Acid (q.v.) and Oil of Bitter Almonds (q.v.). Benzoic acid is regarded as C_6H_5COOH , while the oil of bitter almonds is the corresponding aldehyde C_6H_5COH . On oxidation cinnamic acid is changed into benzoic acid.

Cinnamon is the aromatic bark of certain species of the genus *Cinnamomum*. This genus belongs to the natural order Lauraceæ, which includes a considerable number of species, natives of

tropical and of subtropical parts of the East. Cinnamon has been in use from the remotest antiquity. It is mentioned in the Old Testament, and by a name almost the same as that which it still bears in most languages. The finest kind is produced by *Cinnamomum Zeylanicum*, or the Ceylon cinnamon-tree. It is still mainly derived from its native island, but was

Cinnamon (*Cinnamomum Zeylanicum*).

introduced into the West Indies in 1782, along with various other plants of the East, and is now cultivated there to some extent. The tree naturally attains the height of 20-30 feet, and is sometimes $1\frac{1}{2}$ foot in thickness, but the cultivated trees are not allowed to grow higher than 10 feet. Its bark is of a grayish-brown colour, internally of a yellowish red. The leaves are oval, 4-6 inches long, with a blunt point, and marked with three principal nerves. They have the taste of cloves. The flowers are of a silky gray on the outside, and a pale-yellowish colour internally. The fruit is somewhat like an acorn in shape; it is a small drupe, brown when ripe. There are two seasons of cinnamon-harvest in Ceylon, the first commencing in April, and the last in November—the former being that in which the chief crop is obtained. The branches of 3-5 years' growth being cut down, the epidermis is scraped away; the bark is then ripped up longitudinally with a knife, and gradually loosened, till it can be taken off. The slices are then exposed to the sun, when, as it dries, it curls up into *quills*, the smaller of which are inserted

into the larger, and the whole tied up in bundles of about 88 lb. each. The wood when deprived of its bark has no aroma, and is used as fuel. When the bark is first taken off it is said to consist of an outer portion, which tastes like common bark, and an inner and highly aromatic portion. In the course of drying, the oil upon which the aroma and flavour depends, is diffused throughout, and the quality of the whole is supposed to depend upon the relative quantities of these portions. Cinnamon is examined and arranged according to its quality by persons who are obliged for this purpose to taste and chew it, although in a short time it produces painful effects on their mouths and tongues. The finest cinnamon is yielded by the young branches of the tree, especially by the numerous shoots which spring up from the stump after a tree has been cut down, and which are cut when about 10 feet long, and of the thickness of an ordinary walking-stick. The smell, particularly of the thinnest pieces, is delightfully fragrant, and the taste pungent and aromatic, with a mixture of sweetness and astringency. It is used like other spices by cooks and confectioners, and also in medicine as a tonic, stomachic, and carminative. The average quantity annually imported into London is about 500,000 lb. Its virtues depend chiefly upon the essential oil which it contains (*oil of cinnamon*). Oil of cassia is very often substituted for this oil, as cassia is for cinnamon. The root of the cinnamon-tree contains camphor. The fruit yields a concrete oil, called *cinnamon gum*, which is highly fragrant, and in Ceylon was formerly made into candles for the exclusive use of the king. Cassia (q.v.) is the produce of another species of *Cinnamomum*.—*C. Loureirii*, a native of Cochin-China and Japan, yields a bark which is preferred by the Chinese to that of *C. Zeylanicum*. A species of cinnamon is found at the elevation of 8500 feet in the Sikkim Himalaya.

The constituents of cinnamon are a volatile oil (*oil of cinnamon*), tannin, starch, mucilage, woody-fibre, resin, colouring matter, and an acid. The oil of cinnamon is generally prepared in Ceylon by grinding the waste pieces of cinnamon broken off in packing, soaking them in sea-water for two or three days, and then distilling. Two oils pass over, one lighter, the other heavier than water. Oil of cinnamon varies in colour from yellow to cherry-red, the yellow variety being considered the best, and is most highly esteemed. *Oil of cinnamon leaf* is prepared from the leaves in Ceylon by a similar process, and is met with in commerce under the name of *clove oil*, which it much resembles in odour. *Cinnamon water* is obtained by adding water to cinnamon, and distilling a large quantity, or by diffusing the *oil of cinnamon* through water by the aid of sugar or carbonate of magnesia. *Spirit of cinnamon* is procured by acting upon cinnamon with spirit of wine and water, and distilling; and *tincture of cinnamon*, by soaking cinnamon in spirit of wine, and straining. The medicinal properties of cinnamon, and its preparation, are aromatic and carminative, and it is serviceable in cases of nausea and vomiting, and in cases of flatulence and spasmodic states of the stomach and alimentary canal.

The genuine Ceylon species of cinnamon is now cultivated in Guiana, St Vincent, the Cape Verd Islands, Brazil, Mauritius, Pondicherry, Guadeloupe, and Java. It yields the best bark when grown on a sandy soil. The name *cinnamon* is from the Hebrew *qinnāmōn*, akin to *qāneh*, 'a reed or cane.'

Cinnamon-stone, a precious stone, of which the finer specimens are highly esteemed; it is regarded as a variety of Garnet (q.v.). Its colour varies from hyacinth red to orange yellow; and when pure it is transparent. It is composed

essentially of silica, alumina, and lime. It is found chiefly in Ceylon.

Cinnyris. See SUN-BIRDS.

Cinq-Mars. HENRI COIFFIER DE RUZÉ, MARQUIS DE, an ill-fated favourite of Louis XIII., was the second son of the Marquis d'Effiat, Marshal of France, and was born in 1620. While yet a boy he was placed at court by Cardinal Richelieu, and here his handsome figure and fascinating manners soon secured him the warm affection of the royal household. At nineteen he was chief-equerry to the king, but his ambition could not brook the delay of waiting for the further stages of the most rapid promotion, but already in his dreams he was a duke and peer of France, and husband of the Princess Maria of Gonzaga. Finding his ambitious projects merely derided by Richelieu, he joined with the king's brother, Duke Gaston of Orleans, in a plot to murder the great cardinal. With this was combined a wider plot with Spain for the destruction of the cardinal's power by arms. The conspiracy was discovered, and Cinq-Mars, with his friend De Thou, was executed at Lyons, 12th September 1642. His story was woven by De Vigny into the well-known romance *Cinq-Mars* (1826).

Cinqué Cento (Ital., 'five hundred'; but really a contraction for 'one thousand five hundred') is a current term for the style alike in art and in literature which arose in Italy about or after the year 1500, and which therefore belongs mainly to the 16th century. It is characterised by the revival of classical taste in all departments of culture, and is frequently used in the same sense as the word *renaissance*, especially as applied to decoration. Among the great *cinquecentisti* in art are Michael Angelo, Raphael, Correggio, Titian, Leonardo da Vinci, and Benvenuto Cellini; in poetry the notabler names are those of Berni, Ariosto, and Tasso. See ITALY, ITALIAN ARCHITECTURE, RENAISSANCE.

Cinquefoil, a common bearing in Heraldry, representing a flower with five petals borne full-faced and without a stalk. If pierced—i.e. perforated in the centre, it should be so blazoned.

Cinquefoil :

in Architecture.

Gules, a cinquefoil pierced ermine, was the coat of the old earls of Leicester; and gules, three cinquefoils argent (sometimes ermine), that of the house of Hamilton in Scotland.—Cinquefoil, in Architecture, is an ornamental foliation in five compartments, used in the tracery of windows, panellings, and the like. The cinquefoil is often represented in a circular form, the spaces between points or cusps representing the five leaves, as in the accompanying illustration.

Cinquefoil, in Botany. See POTENTILLA.

Cinque Ports. The five great ports on the coast of Kent and Sussex lying opposite to France—Sandwich, Dover, Hythe, Romney, and Hastings—were of considerable importance during the Anglo-Saxon period; and in a charter of Edward I. we find reference to a previous document granted them by Edward the Confessor. But it was subsequent to the battle of Hastings that the Conqueror, in order that he might wield the resources

of the seaports with greater vigour, constituted this whole line of coast into a jurisdiction entirely separate from the counties of Kent and Sussex, and erected it into a sort of county palatine, under a warden or guardian, the seat of whose administration was in Dover Castle. The warden, whose office corresponded to that of the ancient Count of the Saxon coast (*Comes littoris Saxonici*), exercised jurisdiction, civil, military, and naval, uniting in his single person the functions of sheriff, custos rotulorum, lord-lieutenant, and admiral. Privileges equal to those originally bestowed on the Cinque Ports were subsequently extended to the so-called *ancient towns* of Winchelsea and Rye; and all the seven municipal towns except Winchelsea had subordinate ports and towns attached to them, which were called *limbs* or *members*. In place of the Saxon terms of *aldermen* and *freemen*, those of *jurats* and *barons* were introduced, and the latter term has always been applied to the representatives of the Cinque Ports in parliament. Their chief function in early times was to furnish such shipping as was required for the purposes of the state, the crown having possessed no permanent navy previous to the reign of Henry VII. In the time of Edward I. they were bound to provide no less than fifty-seven ships, fully equipped and manned at their own cost; though the weight of this heavy burden was somewhat lessened by the provision that the period of gratuitous service should be limited to fifteen days. The ports, moreover, enjoyed in return for their services many privileges, such as exemption from tax and tallage, the right to make their own bylaws, &c. In consequence of the warlike navy which they were thus compelled to maintain, the Cinque Ports became so confident and audacious as not only to undertake piratical expeditions, but even to make war and form confederacies as independent states. Previous to the Revolution of 1688, the lord-wardens nominated one and sometimes both of the parliamentary representatives for each of the Cinque Ports; but in 1689 an act was passed to 'declare the right and freedom of election of members to serve in parliament for the Cinque Ports.' The Acts of 1832 and 1885 reduced the number of members sent to parliament by the Cinque Ports from sixteen to three, and the Municipal Reform Act has broken up the ancient organisation of the ports, and assimilated their internal arrangements to those of other English municipalities. The ancient courts of Shepway, Brotherhood, and Guestling are still occasionally held, but their powers scarcely extend beyond matters of form. The lord-warden's jurisdiction, in relation to civil suits and proceedings, was abolished in 1835; but he still presides in the court of Shepway, and appoints the justices of peace within the jurisdiction of the Cinque Ports. His official residence is Walmer Castle, near Deal, a structure of Henry VIII.'s time; and here, as warden, the Duke of Wellington lived every autumn from 1829 till his death at it in 1852. See Montagu Burrows, *Cinque Ports* (1888).

Cintra, a small but picturesquely situated town in Portugal, in the province of Estremadura, 17 miles WNW. of Lisbon, with a population of 5500. It stands on the declivity of the Serra de Cintra, and is surrounded by country residences. There is a palace at Cintra, a strange mixture of Moorish and Christian architecture, anciently occupied by the Moorish kings, and subsequently a favourite summer-resort of the Christian monarchs. On another hill-top stands La Penna, once a convent, now also a residence of the kings of Portugal. In the neighbourhood is the Cork Convent, which derives its name from the cells—which are cut out of the rock—being lined with cork to prevent damp. Cintra is historically remarkable for the

Convention signed here, August 22, 1808, between the English and French, by which the latter agreed to evacuate Portugal, on condition of not being treated as prisoners of war, but landed on the coast of France, retaining their arms and effects. This convention excited the greatest public indignation both in the Peninsula and in England; and the British ministry were obliged to have the generals who signed the convention tried by a court-martial, which, however, resulted in their acquittal.

Ciotat, LA, a town in the French department of Bouches-du-Rhône, on a bay in the Mediterranean, 23 miles SE. of Marseilles by rail. It has a good and commodious harbour, the extensive workshops of the Messageries Maritimes Company, and a great coral fishery. Pop. 8901.

Cipher. See CRYPTOGRAPHY and MONOGRAM.

Cipriani, GIAMBATTISTA, history-painter and designer, was born at Florence in 1727, of an old Pistoja family. He received some instruction from an English painter, Heckford, who had settled at Florence, and he studied for three years in Rome. In 1755 he was induced by Sir William Chambers and Wilton the sculptor to settle in London, where his graceful drawings, which were reproduced by the graver of Bartolozzi, gained great popularity, and exercised a favourable influence upon the English school of figure-painters. He was a member of the St Martin's Lane Academy, and in 1768 was elected a foundation member of the Royal Academy, to whose exhibitions he contributed till 1779, and whose diploma he designed in 1768. His pictures, of which some are preserved at Houghton, are less successful than his designs, being feeble, poor in colour, and with little expression. As an etcher he is known by a few plates in Holli's *Memoirs*. He married in 1761 an English lady of fortune, and died at Hammersmith, 14th December 1785.

Circœa, a small and unimportant but widely distributed genus of rather pretty little Onagraceous herbs. *C. lutea*, frequent in shady situations, bears the name of Enchanter's Nightshade, and in Germany Hexenkraut (Witches' Herb). The origin of these names is not easily explained, as the plant possesses no remarkable properties, being merely a little astringent.

Circars, THE NORTHERN (*Sarkar*, 'a government'), is the historical name for an Indian territory lying along the coast of the Bay of Bengal, from 18 to 100 miles wide, with an area of 17,000 miles. It nearly corresponds with the present Madras districts of Ganjam, Vizagapatam, Godavari, Kistna, and parts of Nellore and Karnul. In 1757 the Circars were ceded to the French by the subahdar of the Deccan; but after a struggle, in which Lord Clive had the chief part, the Delhi court in 1766 granted the Circars to the East India Company; but not till 1823 did they become really a British possession.

Circassia, a territory on both sides of the western Caucasus. See CAUCASUS.

Circassians, in the wide sense of the term, is the name given to all the formerly independent tribes of the Caucasus; in a narrower sense, it denotes the tribes (called by themselves *Adighe*, by the Turks and Russians, *Tcherkesses*) who inhabited the north-western wing of the Caucasus, with a government half patriarchal and feudal, and half constitutional. In 1858-65, rather than submit to Russian government, nearly the whole nation of fifteen tribes, to the number of nearly half a million persons, left their country for the Turkish possessions in Asia Minor, or the mountainous parts of Bulgaria, carrying with them their in-

subordinate spirit and marauding habits, which added to the horror of the Bulgarian massacres of 1876 and 1877.

The Circassian nobles are principally Mohammedans, whilst the great mass of the people profess a corrupt Christianity, which shows strange survivals of earlier heathenism in its sacrifices and sacred trees, joined to the celebration of Easter, the sign of the cross, and processions with lights. The Circassians are proverbially handsome—for generations their daughters have adorned the harems of the wealthy Turks; they are also strong, active, brave, and temperate. As a nation they made their first historical appearance during the middle ages. They are, however, chiefly known through their long struggles to maintain their independence against the aggression of Russia. See article CAUCASUS, and Ernest Chantre's magnificent work, *Recherches anthropologiques dans le Caucase* (5 vols. folio, Paris-Lyons, 1885-87). The first volume contains an exhaustive bibliography; the fifth is devoted to a detailed account of the peoples of the Caucasus as they now exist.

Circe, a sorceress of ancient Greek story, described in the *Odyssey* as 'fair-haired, a clever goddess, possessing human speech,' sister of 'all-wise Æetes,' daughter of 'the Sun, who gives light to mortals, and of Perse, whom Ocean begot as his daughter.' Round her palace in Æra were numbers of human beings, whom she had changed into the shapes of wolves and lions by her drugs and incantations. She changed two-and-twenty of the companions of Ulysses into swine; but that hero, having obtained from Mercury the herb *Moly*, went boldly to the palace of the sorceress, remained uninjured by her drugs, and induced her to disenchant his comrades. He remained with her for a year; and when he departed, she instructed him how to avoid the dangers which he would encounter on his homeward voyage. Ovid relates how, when she was jealous of Scylla, whose love was sought by Glaucus, she poured the juice of poisonous herbs into that part of the sea where her rival was accustomed to bathe, and so changed her into a hideous monster.

Circle, a plane figure bounded by a curved line called its *circumference*, which is everywhere equally distant from a point within it called the *centre*. The circumference is sometimes itself called the circle, but in geometry that term is properly applied only to the surface or area bounded by the curve. Any line drawn through the centre, and terminated by the circumference is a *diameter*, which is therefore bisected in the centre (see ARC, CHORD). In Co-ordinate Geometry, the circle ranks as a curve of the second order, and belongs to the class of the conic sections. It is got from the right cone by cutting the cone by a plane perpendicular to its axis. The circle may be described mechanically with a pair of compasses, fixing one foot in the centre, and tracing out the curve with the other held at a fixed distance. The following are some of its leading properties:

1. Of all plane figures having the same perimeter, the circle contains the greatest area.
2. Of all plane curves, the circle alone has the same curvature at every point.
3. The circumference of a circle bears a certain constant ratio to its diameter. This constant ratio, which mathematicians usually denote by the Greek letter π (perimeter), has been determined to be 3.14159, nearly, so that, if the diameter of a circle is 1 foot, its circumference is 3.14159 feet; if the diameter is 5 feet, the circumference is 5×3.14159 ; and, in general, if the diameter is expressed by $2r$ (twice the radius),

then c (circumference) $= 2r \times \pi$. Archimedes, in his book *De Dimensione Circuli*, showed that the ratio is nearly that of 7 to 22. Various closer approximations in large numbers were afterwards made, as, for instance, the ratio of 1815 to 5702, 1010 to 3173; or the excellent one of Adrian Metius—viz. 113 to 355. Vieta in 1579 showed that if the diameter of a circle be 1000, then the circumference will be greater than 3141·5926535, and less than 3141·5926537. This approximation he made by ascertaining the perimeters of the inscribed and circumscribed polygons of 393,216 sides. By increasing the number of the sides of the polygons, their perimeters are brought more and more nearly into coincidence with the circumference of the circle; but this operose method was long ago superseded by easier modes derived from the higher mathematics. Suffice it to say that various series were formed expressing its value; by taking more and more of the terms of which into account, a closer and closer approach to the value can be obtained by ordinary arithmetic. We subjoin some examples:

$$(1) \pi = 4 \left(1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \frac{1}{11} + \frac{1}{13} - \frac{1}{15} + \dots \right).$$

$$(2) \pi = 8 \left(\frac{1}{1.3} + \frac{1}{3.5} - \frac{1}{3.5.7} + \frac{1}{5.7.9} - \frac{1}{7.9.11} + \&c. \right).$$

$$(3) \pi = 16 \left(n - \frac{n^3}{3} + \frac{n^5}{5} - \frac{n^7}{7} + \dots \right) \div 4 \left(m - \frac{m^3}{3} + \dots \right)$$

where $n = \frac{1}{5}$ and $m = \frac{1}{259}$.

$$(4) \pi^2 = 6 \left(\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \dots \right)$$

$$= 8 \left(\frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \dots \right).$$

Series (3), or one of its modifications, is the most expeditious mode yet known of extending the approximation to the ratio π . It has now been calculated to 707 places of decimals, and verified to over 600. The number π , though fixed in value, cannot be exactly expressed in figures, being *Incommensurable* (q.v.). Finally, the multiplier $(3 - .008 - .000,007) (1 + \frac{1}{259})$ gives a close approximation, useful to the practical arithmetician.

4. The area of a circle is equal to π multiplied by the square of the radius ($= \pi r^2$); or to the square of the diameter multiplied by $\frac{\pi}{4}$; i.e. by .7854. Archimedes proved this by showing that the area is equal to that of a triangle whose base is the circumference, and perpendicular height the radius of the circle.

5. It follows that different circles are to one another as the squares of their radii or diameters, and that their circumferences are as the radii or diameters.

The circle is almost always employed in measuring, or comparing angles, from the fact demonstrated in Euclid (Book vi. Prop. 33), that angles at the centre of a circle are proportional to the arcs on which they stand. It follows from this, that if circles of the same radii be described from the vertices of angles as centres, the arcs intercepted between the sides of the angles are always proportional to the angles. The easiest subdivision of a circumference is into six equal parts, because then the chord of the arcs is equal to the radius. Divide one of these arcs into sixty equal parts, and we thus obtain the unit of the *sexagesimal scale*, called a *degree*. Each degree is divided into 60 *seconds*, and each second into 60 *thirds*, and so on. According to this scale, 90° represents a right angle; 180°, two right angles,

or a semicircle; and 360°, four right angles, or the whole circumference—the unit in the scale being the $\frac{1}{360}$ th of a right angle. As the divisions of the angles at the centre, effected by drawing lines from the centre to the different points of graduation of the circumference, are obviously independent of the magnitude of the radius, and therefore of the circumference, these divisions of the circumference of the circle may be spoken of as being actually divisions of angles. By laying a graduated circle over an angle, and noticing the number of degrees, &c. lying on the circumference between the lines including the angle, we at once know the magnitude of the angle. Suppose the lines to include between them 3 degrees, 45 minutes, 17 seconds, the angle in this scale would be written 3° 45' 17".

The sexagesimal measurement of circumferences and angles is the most ancient, and still recommends itself universally to practical mathematicians. A second mode was proposed at the French Revolution, but though adopted by Laplace in the *Mécanique Céleste*, has long been abandoned even in France. By this scale, called the *centesimal*, the right angle is divided into 100 degrees, while each degree is divided into one hundred parts, and so on. Such a quantity as 3° 45' 17" is expressed in this notation by 3·4517, the only mark required being the decimal point to separate the degrees from the parts. Of course, in this illustration, 3° means 3 centesimal divisions of the right angle, and 45' means 45 centesimal minutes, and so on. If we want to translate ordinary degrees into the centesimal notation, we must multiply by 100, and divide by 90. To translate minutes in the same way, multiply by 100, and divide by 54; and for seconds, multiply by 250, and divide by 81.

There is also a theoretical method of measuring angles, which, though indispensable in advanced trigonometry and other branches of analysis, is scarcely required in elementary mathematics. For the *circular measure*, as it is called, the unit angle is thus found: Let POA be an angle at the centre O of a circle, the radius of which is r ; APB a semicircle whose arc are accordingly $= \pi r$; and let the length of the arc AP $= a$. Then, by Euclid,

$$\frac{\text{angle POA}}{2 \text{ right angles}} = \frac{a}{\pi r}; \text{ and } \angle \text{POA} = \frac{2 \text{ right angles}}{3.14159, \&c.} \cdot \frac{a}{r}.$$

Now, supposing a and r to be given, although the angle POA will be determined, yet its numerical value will not be settled unless we make some convention as to what angle we shall call unity. We therefore choose such a one as will render the preceding equation the most simple. It is made

most simple if we take $\frac{2 \text{ right angles}}{3.14159\dots} = 1$. We

shall then have (denoting the numerical value of the angle POA by θ) $\theta = \frac{a}{r}$. The result of our convention is, that the numerical value of two right angles is π , instead of 180°, as in the method of angular measurement first alluded to; and the unit of angle, instead of being the ninetyeth part of a right angle, is $\frac{2 \text{ right angles}}{3.14159\dots}$, or 57° 17' 44" 48".

nearly. Making $\theta = 1$ in the equation $\theta = \frac{a}{r}$, we have a (or AP) $= r$ (or AO), which shows that in the circular measure the unit of angle is that angle which is subtended by an arc of length equal to

radius. Thus the circular measure of 180° is π , or 3.14159 , &c., $90^\circ = \frac{1}{2}\pi$, $60^\circ = \frac{1}{3}\pi$, $45^\circ = \frac{1}{4}\pi$, and so on; and since π is a fixed number, any angle is thus represented *absolutely*, and not as a part or multiple of another angle—i.e. an abstract number will as exactly denote an angle as it does the length of a line. If we say $\theta = 3$, then in degrees $\theta = 3 \times (57^\circ 17' 45'')$; if $\phi = \frac{1}{2}$, then $\phi = \frac{1}{2} \times (57^\circ 17' 45'')$ sexagesimally. For the squaring or quadrature of the circle, see **QUADRATURE**; for the circles of the sphere, see **ARMILLARY SPHERE**; see also **MURAL CIRCLE**.

Circle, MAGIC, a space in which sorcerers were wont to protect themselves from the fury of the evil spirits they had raised. This circle was usually formed on a piece of ground about nine feet square (in the East seven feet appears to have been considered sufficient), in the midst of some dark forest, churchyard, vault, or other lonely and dismal spot. It was described at midnight in certain conditions of the moon and weather. Inside the outer circle was another somewhat less, in the centre of which the sorcerer had his seat. The spaces between the circles, as well as between the parallel lines which inclosed the larger one, were filled 'with all the holy names of God,' and a variety of other characters supposed to be potent against the powers of evil. Without the protection of this circle, the magician, it was believed, would have been carried off by the spirits, as he would have been had he by chance got out of the charmed space. Another figure which, described upon the ground, could bar the passage of a demon, was the *pentagram*. Readers of *Faust* will remember its effect upon Mephistopheles.

Circles. STONE. See **STANDING STONES**, **STONEHENGE**, **CALLERNISH**.

Circuits. See **ASSIZE**.

Circular Notes are bank-notes specially adapted for the use of travellers in foreign countries; and being, in fact, bills personal to the bearer, they are believed to be more safe as travelling money than ordinary notes or coin. Circular notes of the value of £10 and upwards are furnished by or through the chief banking-houses. Along with these notes is given a 'letter of indication.' This letter (a lithographed form in French) is addressed to foreign bankers, requesting them to pay the notes presented by the bearer, whom they name, and to aid him in any way in their power. On the back of the letter there is a long list of foreign bankers, extending all over Europe, any of whom will cash one of the circular notes on being presented and indorsed by the bearer. In paying these notes the money of the country is given according to the rate of exchange, and free of any charge for commission. For security, the letter and the notes should not be carried together, in case of their being stolen or lost. A corresponding certificate issued by the bankers in the United States for the use of travellers, is called **Letter of Credit**. See **CREDIT**.

Circular Numbers are numbers whose powers end on the same figure as they do themselves: such are numbers ending in 0, 1, 5, 6.

Circulating Library. See **LIBRARY**.

Circulation, in Anatomy and Physiology, is the term used to designate the course of the blood from the heart to the most minute blood-vessels (the Capillaries, q.v.), and from these back to the heart. To simplify the consideration of the subject, we shall consider—(I.) the General Anatomy, (II.) the Comparative Anatomy, (III.) the Physiology, and (IV.) the History.

I. The organs of circulation consist of the heart, arteries, veins, and capillaries. The course of the blood through these organs will be best elucidated

by the aid of a diagram, which is equally applicable for all other mammals as well as for man, and for birds. The dark parts

of fig. 1 represent the course of the impure or venous blood, while the lighter portions represent the course of the pure or arterial blood. Two of the four chambers of the heart (A and C) receive the inflowing blood, and are termed the *auricles*; while the other two chambers (B and D) drive the blood to the lungs and to the general system respectively, and are termed the *ventricles*. The vessels that bring blood to the auricles are termed *veins*, and the vessels through which the blood is driven from the ventricles are known as *Arteries* (q.v.). We will now trace the course of the blood, as indicated by the arrows of the diagram, commencing with the right auricle, A. The right auricle contracting upon the venous or impure blood with which we suppose it to be filled, drives this into the right ventricle, B, through an opening guarded by a triple (or tricuspid) valve, which almost entirely prevents the regurgitation of the blood from the ventricle into the auricle. The ventricle, B, being now filled, contracts, and as the blood cannot return into the auricle, it is driven along the dark vessel, c, which is the pulmonary artery, conveying the blood to the lungs. At its commencement it is guarded by crescent-shaped (semilunar) valves, which entirely prevent the blood which has once been propelled into the pulmonary artery from re-entering the ventricle. The pulmonary artery gradually divides into smaller and smaller branches, which ultimately emerge into capillaries freely distributed over the interior of the air-cells of the lungs. There the blood gives off carbonic acid gas, and absorbs oxygen, becoming thereby 'pure.' The capillaries, in which the blood is purified, gradually unite to form larger vessels, and finally the blood is collected into the pulmonary veins, which pour their contents into the left auricle, C. Thence it is propelled into the left ventricle, D, through an opening guarded by a double (mitral or bicuspid) valve, which entirely prevents the reflux of the blood. The left ventricle contracts and drives its contents into the large artery, e, or Aorta (q.v.), which by means of its various branches supplies the whole body with pure blood. From the aorta and its various subdividing branches the blood passes into the capillaries, J, H, which occur in every part of the system. In these capillaries it parts with its oxygen to the tissues, and becomes charged with the waste carbonic acid gas. The capillaries unite into larger veins, and these gradually unite to form two large trunks, a, b, the superior and inferior *vena cava*, which pour their contents into the right auricle—the point from which we started. The diagram also shows how the venous blood from the viscera, G, instead of passing directly into the

Fig. 1.—Diagram of Circulating System (from 'Leunis').

vena cava, goes through the liver, F, in what is known as the hepatic-portal system.

Before passing to the comparative study of the circulation, we must notice a few of the above

facts in greater detail. The Heart (q.v.) is described in a separate article. Since all the arterial blood leaves the heart through the aorta, to trace the circulation of the pure blood involves following the branches of that great vessel. For this see AORTA. It is sufficient, without further anatomical details, to say that the ramifications of the arteries distribute the arterial blood to the capillaries (q.v.) which pervade every part of the body. It is already evident that the pulmonary arteries from the right ventricle carry impure blood to the lungs, and that pure blood returns from the lungs to the left auricle by the pulmonary veins.

The *veins*, like the arteries, are found in nearly every tissue; they commence in minute networks

which communicate with the capillaries. Branches from these networks uniting together, form veins, which, by joining, increase in size as they pass onward towards the heart. If we except certain venous structures (called *sinuses*) occurring in the interior of the skull, we may divide the veins into two sets—the *superficial* or *cutaneous*, and the *deep* veins. The deep veins accompany the arteries, and are usually inclosed in the same sheath of tissue. In the case of the smaller arteries they generally exist in pairs, one on each side of the artery, while the larger arteries have usually only one accompanying vein. The superficial veins occur immediately beneath the integument; they not only return the blood from the skin and adjacent structures, but communicate with the deep veins. All the veins finally lead by two large trunks, the *superior* and *inferior vena cava*, into the right auricle of the heart. The superior vena cava is formed by the union of the veins from the head and neck (the jugulars) with those from the arms (the subclavians), while the inferior vena cava brings back the blood from the lower extremities, the trunk, and the viscera.

We must refer to the article *VEIN* for the structure of the walls of this part of the circulatory system. There is only one point that imperatively requires notice here—viz. that while the arterial system presents no valves except at the points where the two great trunks leave the heart, the veins contain a great number of valves, which are formed by a doubling of their lining membrane, and resemble pocket-like folds or pouches, which allow the blood free passage toward the heart, but prevent its reflux. The veins are much less elastic than the arteries, and their total capacity is much greater.

There is one part of the venous circulation which, from its great importance, requires special notice

—viz. that of the spleen, pancreas, stomach, and intestinal canal. The blood supplied to these organs by the celiac and the two mesenteric arteries is not returned directly to the inferior vena cava, but passes by several veins into one large vessel—the portal vein, which enters the liver, and breaks up into a capillary network. There the blood undergoes important changes associated with the bile-secreting and glycogen-forming functions of the liver. The blood, entering the liver from two sources, from the portal vein and from the hepatic artery, leaves it by the hepatic veins, which join the inferior vena cava. It is also important to notice the entirely distinct set of vessels known as lymphatics, which conduct the products of digestion into the veins (see *LYMPH*).

The above-described double circulation (through the lungs and through the body) is exhibited by the blood from the time of birth during the whole period of life. The circulation of the blood, however, begins before birth—indeed, at a very early period of intra-uterine or fetal existence; and the circumstance that before birth the lungs do not act as organs of respiration induces a very important modification in the course of the blood in fetal life which will be described under *FETUS*.

II. *Comparative*.—The circulatory system in man, as above described, may serve as type of the highest development, differing but slightly from that of other mammals, or that of birds. It is convenient now to begin at the other end, and to note briefly the salient steps of progress in the gradual evolution of the system throughout the animal series. In the unicellular animals the movement of the protoplasm and the special activity of 'contractile vacuoles,' represent, to some extent at least, a circulatory function before the appearance of any system. The canals which so completely irrigate a sponge, likewise illustrate in low expression a circulatory system not yet separated off from the others. In *Celenterates*, too, the system is still unseparated: 'gastro-vascular' prolongations of the alimentary cavity penetrate the body, as may be very well seen in the disc of a common jelly-fish. In the lower worm-types also, where no distinct body-cavity is yet developed, the nutritive fluid simply diffuses through the body, and no vascular system is differentiated. But in higher worms there is generally a body-cavity, and with it the gradual appearance of a definite vascular system. In some we simply find a fluid moving in the body-cavity, occasionally clear, usually with corpuscles; in others, portions of the body-cavity are separated off as blood-spaces, or eventually as blood-vessels; these may remain in connection with the general cavity, or may at length form a closed system. The manifold worm-types afford abundant illustration of all the stages in this differentiation. In the bristle-footed worms (*Chatopods*, q.v.), and in some others, the perfecting of the blood-driving mechanism may be instructively traced. Often a dorsal vessel is diffusely contractile, less frequently the ventral; or there may be contractile connecting loops between dorsal and ventral vessels, as in the earthworm; or lastly, a special region in the dorsal vessel may become the main seat of the vascular contractility. Such a *dorsal* heart is found from this point onwards throughout the *Arthropods* and *Molluscs*. (The well-developed and very difficult vascular system of *Echinoderms*, which co-exists with an abundant body-cavity fluid with relatively few corpuscles, has no special interest for this general survey.) In *Crustaceans*, the dorsal heart, usually inclosed in a special space or 'pericardial sinus,' drives blood by more or less well-developed arteries through the body. The rest of the system is best described as lacunar.

Fig. 2.—Theoretical Section of the Human Heart:

f, *b*, the two *venae cavae*, opening into *d*, the right auricle; *c*, the tricuspid valve; *a*, the right ventricle, from which proceeds the pulmonary artery, dividing into branches *g* and *i*, going to the right and left lung respectively; *e*, *e'*, the pulmonary veins (two from either lung), entering into the left auricle; *k*; *l*, the mitral valve; *m*, the left ventricle, from which proceeds the aorta, whose arch is indicated by *h*, and the descending portion by *n*, none of its branches being indicated in this figure; *o*, the partition, or *septum*, between the right and left hearts.

The venous blood passes along body-cavity spaces to the gills for purification, thence returns to the pericardial sinus, and entering the heart is redistributed. In insects a chambered dorsal heart, inclosed in a sinus as before, drives the blood forward, but as one would expect from the very efficient respiratory apparatus, the general vascular system is but slightly differentiated. The blood, purified by diffusion from the everywhere present air-tubes, passes back by venous channels into the sides of the pericardium and heart. In myriapods, scorpions, and king-crab, the system is more definitely developed, but illustrates no new advance except that of more complete establishment and wider extension of vessels. In molluscs, however, some progress is observable. Except in the Elephants' Tooth Shell (*Dentalium*), a heart is present, and the arterial system is often very well developed, even to the extent of capillaries in some cuttle-fishes and snails. Usually, however, the venous blood travels along lacunae, though gradual transitions occur between these and true veins. The blood purified in the gills or pulmonary chamber passes back into a special portion of the body-cavity—the pericardium, and thence into the heart. In certain worm-types, several contractile lateral vessels may often be observed to enter the dorsal vessel; in the Pearly Nautilus, which has four gills, four efferent vessels dilating into four indistinct auricles, enter the median dorsal heart or ventricle; in almost all bivalves the entrant dilations or auricles are reduced to two, one on each side; while in most Gasteropods and Pteropods the specialisation has gone further, and the heart consists of a single auricle and a thicker muscular ventricle. The latter drives the blood through the body by a single or double aorta.

Passing now with equal brevity through the vertebrate series, we notice first that the heart arises as a dilatation no longer of a dorsal, but of a ventral vessel. Up to and including amphibians, the heart begins as a specialisation of the 'sub-intestinal vein' in the throat region; in most, if not all higher vertebrates, it arises from the fusion of two vessels. It always lies in a pericardial sac.

(1) Among the degenerate Tunicata there is considerable variety in the vascular system. In one case no heart is present; in several there are no definite vessels or blood-corpuscles. The main point, however, is that in most cases a tubular ventral heart drives blood to the respiratory pharynx. In all cases where the heart has been observed, the direction of its beats has been seen to undergo reversal at regular short intervals, a phenomenon which has also been noticed as a rarity in certain worm-types.

(2) The vascular system of the lancelet or amphioxus is of a peculiarly diffuse and undifferentiated nature. It has in one sense no heart, in another sense many; for while there is no main centre of contractility, there are small pulsating dilatations at the bases of the vessels passing to the gill-slits, while the portal vein and ventral vessel in the anterior pharyngeal region are both said to be contractile. In general course, the circulation is like that of a fish; the blood passes from ventral vessel to respiratory region, thence to dorsal aorta, thence to body, thence by united sub-intestinal veins to the liver caecum, and thence to the ventral vessel from which it started.

(3) In the Round Mouths (Cyclostomata) the typical fish-circulation is established. The muscular ventricle drives the blood by a ventral vessel ('ventral aorta') to the gill-sacs; thence the purified blood is gathered into efferent dorsal vessels, which form in uniting the 'dorsal aorta.' The latter gives off branches to the greater part

of the body, the head-region being directly supplied from the anterior efferent branchials. The blood returns from the anterior and posterior regions into a uniting vessel behind the heart ('the *sinus venosus*'), thence into the receiving auricle, and from that to the muscular ventricle.

(4) It is enough after the above to notice in regard to the fishes proper, that with the exception of the double-breathing mud-fish (*Dipnoi*), the heart never contains anything but impure blood, that it drives this wholly to the respiratory organs, and is in no direct degree 'systemic.' The 'dorsal aorta' supplying most of the body is formed from the union of efferent branchials, and does not arise, as in higher vertebrates, from the heart. It is important to notice that the five or so arches which spring from the ventral aorta are almost all quite alike, and arise (except in *Dipnoi*) at slight intervals from one another. A great part of the differentiation in higher vertebrates obviously concerns these aortic arches, which are seen in *Oclostomata* and fishes in primitive uniformity, but become modified in higher vertebrates into the carotids, sub-clavians, aortic arches, and pulmonary arteries. The heart of a fish consists of the *sinus venosus* or general junction, running transversely behind the heart (persisting hence onwards, except in adult birds and mammals), of the auricle and ventricle, and except in Teleostei of a specialised contractile portion of the latter

Fig. 3.—Arterial System of Fish:

H, heart; c and c', anterior and posterior cardinal veins; a, branchial arteries; R, capillaries of the branchial vessels; b, branchial veins; ce, head circle; ca, carotids; RA, root of the aorta; A, dorsal aorta; E, artery to viscera (coeliaco-mesenteric); N, renal arteries. (After Wiedersheim.)

Fig. 4.—Arterial System of Amphibian:

ra, right auricle; la, left auricle; v, ventricle; ca, conus arteriosus; c, carotid arteries; aa, aortic arches; ao, dorsal aorta; pa, pulmonary artery; pv, pulmonary vein; ra receives venous blood from body; both the pulmonary arteries enter la. (After Nuhn.)

known as the *conus arteriosus*. A dilatation of the beginning of the ventral aorta is distinguished as the *bulbus arteriosus*. In regard to the general system, it is worth noticing that in fishes (as in amphibians and all reptiles except Chelonians) there is a renal portal, as well as an hepatic portal system. Veins from the caudal region of the fish come into the same relations with the kidneys as the portal veins do in regard to the liver. The hepatic veins returning from the liver do not unite with the other posterior veins, but enter the *sinus venosus* independently. Thus fishes have no *inferior vena cava*. (4a) The *Dipnoi* are interesting as leading on to amphibians. The

heart receives pure as well as impure blood, drives blood to lungs in addition to gills, is in part systemic (driving pure blood in *Protopterus* and *Lepidosiren* through the first two pairs of arches), has the roots of the aortic arches close together, and is practically three-chambered. In these respects it reaches forward to the condition seen in those amphibians which retain their gills.

(5) The heart of amphibians is three-chambered, a right auricle receiving impure blood from the body, a left auricle receiving purified blood from the lungs or from the lungs and gills, a single ventricle which drives the blood, mingling less than might be supposed, to head or body or respiratory organs. In some cases, as one would expect, the partition between right and left auricle is imperfect. In the tadpoles at the fish-like stage there are four aortic arches, of which the first three supply gills. Where gills persist, such supply is always of course in some degree maintained. In such a metamorphosis as that of the frog, where all trace of gills is lost, the first branchial arch becomes the carotid; the second is the systemic, which forms, by uniting with its fellow, the dorsal aorta; the third dwindles away; the fourth supplies the lungs. The same is generally true of the higher vertebrates, except that it is usually the third branchial which forms the pulmonary artery. An inferior *vena cava* is definitely established in amphibians; there is a renal portal as well as an hepatic portal system; special lymph hearts are sometimes present connecting the lymph system with the vascular.

(6) Among the reptiles, the differentiation of the heart goes a step further. In Chelonians, Lacer-tilia, and Ophidia, a strong muscular ridge forms an incomplete partition, dividing the ventricle into a right portion containing purely venous blood,

Fig. 5.—Circulation of a Reptile (Tortoise):

ra, right auricle; *la*, left auricle; *rv*, right (venous) portion of ventricle; *lv*, left (arterial) portion of ventricle; *laa*, left (venous) aortic arch; *pa*, pulmonary artery; *rao*, right (arterial) aortic arch; *rs*, *ls*, branches to fore-limbs; *ca*, carotids; *pv*, pulmonary veins; *svc*, superior vena cava; *ivc*, inferior vena cava; *ao*, dorsal aorta; *cael*, celiac artery to viscera. (After Nuhn.)

and a left portion containing mixed and arterial blood. The pulmonary artery rising from the right cavity takes purely venous blood to the lungs; of the two aortic arches rising from the left cavity, the left aorta contains more venous than arterial blood, the right aorta more arterial than venous. In Crocodylia, however, there is a complete septum

in the ventricle, and thus for the first time a four-chambered heart, though it is not certain that the division is exactly comparable to that of birds and mammals. From the right or venous ventricle rise the pulmonary artery and left aortic arch (taking venous, not mixed, blood to the viscera); from the left or arterial ventricle rises the right aorta, with pure blood to the greater part of the body. Though the division of arterial and venous chambers brings the crocodilian heart to the bird or mammal level, there are two aortic arches, one venous, the other arterial, which unite as usual, and also communicate by a foramen at their roots. In all reptiles there are two superior *venae cavae*, an inferior *vena cava* formed from the union of the two efferent renals, and a renal portal system except in Chelonina. In birds and mammals a single aortic arch forms the dorsal aorta, not two or more as in reptiles. In birds the aorta goes to the right, in mammals to the left, but except in this variation and in the structure of the Heart (q.v.), the circulation in Birds (q.v.) and mammals (*supra*) is practically identical.

III. *Physiology*.—The most important conditions of circulatory function are (1) a general constancy and rapidity of flow, and (2) a power of adapting this to special needs. The conditions of the former are mainly mechanical and physical—those of the latter depend upon the nervous system.

(1) *The Mechanism of Circulation* chiefly depends upon the rhythmic contractility of the heart, the elasticity of the vessels, and the friction in the small arteries and capillaries. The heart is a muscular pump contracting under the influence of its automatic nervous mechanism, but also responding in the nature of its beat to the conditions of the body. The human heart usually beats about seventy-two times a minute, and in the eight-tenths of a second occupied by each beat, three distinct events occur—the contraction (*systole*) of the ventricles, a 'passive interval' of relaxation (*diastole*) of both auricles and ventricles, and the decidedly briefer contraction of the auricles. The pumping action of the heart is thus obviously an intermittent force which drives the blood through the closed series of elastic tubes formed by the blood-vessels. To the latter attention must now be directed.

The *arteries* are surrounded by muscular tissue, and are contractile as well as highly elastic. As they break up into branches from the *aorta* to the capillaries, the capacity for holding blood is continually increasing. The flow of blood within them, though continuous, comes in gushes corresponding to the heart-beats. The velocity of the stream is greatest the nearer the heart. The *veins* are much less elastic than the arteries, and have a much greater total capacity for holding blood. As they unite from the capillaries to the *venæ cavae*, the total capacity is continually diminishing. The flow of blood within them is continuous, but with relatively little force and small velocity. The *capillaries* have a very small calibre, but are both elastic and contractile. They are permeable by fluids, and also allow the corpuscles to pass through their walls. The velocity of the flow is here at its minimum. The resistance to the flow of blood, due to the friction of these minute passages, works back along the arterial system to the heart, and is one of the most important factors in determining the nature of the circulation.

To return now to the actual mechanism, it is only necessary to note (a) that the whole system is always over-filled with blood, which consequently causes a pressure on the walls; (b) that the cause of the circulation is the difference of pressure between the blood in the aorta and pulmonary arteries on the one hand and the venæ cavæ and pulmonary veins on the other; (c) that this difference of

pressure is due to the contraction of the heart; and (d) that the interrupted current, which would naturally arise from the intermittent action of the heart, becomes continuous because of the rapidity of the beats, the resistance in the small arteries and capillaries, and the elasticity of the arterial walls.

(2) *The Control of the Circulation.*—The phenomena referred to above are mainly physical and mechanical, and in their essential features can be readily reproduced on a model. But in a complex living organism there is a constant necessity for modifiability. The organs vary in their requirements, and the external conditions are frequently changing. Modifications in the circulation are brought about by changes in the heart's beat, and in the calibre and resistance of the small arteries. Both these changes are under the direct control of the Nervous System (q.v.). Modifications of less importance also occur in the capillary resistance and in the total quantity of blood; but the important point is simply the general fact that the requirements of the organism are met by the dominion of the nervous system over the circulation.

IV. *History.*—Aristotle and the ancients thought of the heart as a blood-fountain, but had no conception of circulation. Galen (131–201) disproved the prevalent notion that the arteries contained air, Calvin's contemporary Servetus demonstrated the pulmonary circulation, and various physiologists had a distinct notion of the centrifugal flow. In 1628 William Harvey published his *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*, in which his discovery of the real nature of the circulation was expounded. Soon after, the use of the microscope revealed to Malpighi (1661) and Leeuwenhoek (1674) what Harvey had been unable to trace—the capillary connection between arteries and veins. Since those days the detailed problems of circulation, the hydraulic mechanism, the action of the heart and its valves, and the nervous control have been worked at by many of the greatest physiologists.

See AORTA, BLOOD, HEART, VEIN, &c.; the physiological text-books of Foster, Hermann, Huxley, Landois, Stirling, &c., for human circulation; works on comparative anatomy (Jeffrey Bell, Claus, Gegenbaur, Huxley, Wiedersheim, &c.), for the gradual evolution of the system; Willis's *William Harvey*, for the earlier notions on the subject.

Circulation of Sap. See PLANT, SAP, VEGETABLE PHYSIOLOGY.

Circumcision (Lat., 'a cutting round'), the cutting off the foreskin, a rite widely diffused among ancient and modern nations. Three thousand years before Christ it was familiar to the Egyptians, who circumcised boys between the sixth and fourteenth year, though it is not certain whether it was extended to all males, or confined to the priestly caste and others who were connected in some special way with the religious mysteries. The ceremony is clearly portrayed on a temple at Karnak, in a drawing copied by Ebers, who adds that most of the male mummies which have been examined are found to have been circumcised. Sayce (*Hibbert Lectures*, p. 83) affirms on precarious grounds that circumcision was known to the Babylonians. In any case it was not generally practised by them. It was known to the Colchians, to some at least of the Phœnicians (compare Ezek. xxviii. 10 with Herodot. ii. 104), and apparently also to the Edomites, Ammonites, and Moabites (see Jerem. ix. 25, 26). Further, it appears among Kaffirs, among many negro tribes, among Mexicans, Indians of South America, and among the islanders of the Pacific Ocean. Its original significance is uncertain, and possibly it may have arisen from different motives in different places. Sanitary

reasons, considering the primitive nature of the nations in which it is found, are out of the question, and of other theories which have been advanced two only are plausible. It may have served like the tattoo to mark and stamp the circumcised person as a member of the tribe, and qualified to take part in its sacred rites, or, which is much more likely, it may have had a sacrificial character, the object being to propitiate the god or spirit by blood, and induce him to spare the life. The former theory is illustrated and defended by Stade (*Gesch. des Volkes Israel*, i. p. 423), the latter by Réville (*Relig. des Peuples non-civilisés*, ii. p. 253). Stade's view finds some support in Ezek. xxviii. 10, xxxi. 18, when he who dies uncircumcised is excluded from communion with the dead who have received this token of initiation. But, in fact, as Réville points out, primitive nations constantly substitute some partial mutilation for the sacrifice of the whole person. See the instructive story, Exod. iv. 24–26. We may add that in some parts of Africa an analogous operation is inflicted upon young females.

The Scripture account of the origin of circumcision amongst the Israelites is given in Gen. xvii. 7–14; but it is plain from what has just been said that circumcision could not have been in itself a sign of distinction between the Israelites and the neighbouring nations; and hence in the books of Judges and Samuel it is the Philistines, and the Philistines only, who are taunted with being uncircumcised; while in Joshua, v. 9, it is implied that the uncircumcised state of the Israelites who had grown up in the desert was 'a reproach' to them in the eyes of the Egyptians. But after the exile circumcision assumed a new prominence, because the nations under whose sway Israel then lived—the Babylonians and Persians—practised no such rite. A deep religious meaning was given to it. It became the sign of the covenant between God and his chosen people, and their devotion to it grew in proportion to the contempt which it excited in their Greek and Roman oppressors.

According to the Levitical law every Jewish male must be circumcised on the eighth day under penalty of being cut off from the congregation of Israel. The same law applied to foreign slaves bought by a Jew or born in his house. Strangers also must circumcise their males if they wished to partake of the Passover (Exod. xii. 48). The rite was performed by the father of the house or by some other Israelite, in case of necessity even by women (1 Macc. i. 60). Modern Jews employ a *mohel* or official who has the requisite surgical skill. The child is brought to the door of the room and handed to the *mohel*, who after prayer circumcises the child, and having drunk a glass of wine, gives it its name (Gen. xxi. 3, 4; Luke, i. 59, ii. 21), and placing his hand on its head blesses it. The Jewish ritual contains special prayers for the feast which follows. Circumcision was excluded from the Christian community after a memorable struggle, in which St Paul was the great champion of spiritual religion. Many of the Jewish converts wished to impose circumcision on the Gentile Christians, not only as a condition of equality, but as an essential to salvation. The result of the first struggle after a conference at Jerusalem was a mutual compromise: circumcision was not to be imposed on the Gentiles, who in return were asked to abstain from meats offered to idols, from blood, from things strangled, and from fornication. Much later, however, circumcision was urged on converts as a title of preference, and it was long before Jewish Christians could be brought to recognise the real supremacy of the gospel, itself a New Covenant in the place of the Old. St Paul speaks of his party (Phil. iii. 3) as the 'true circumcision,' and by a

bold metaphor applies the word *concision* (*kata-tomé*), which in the Septuagint was applied only to mutilations and incisions forbidden by the Mosaic law, to the vaunted circumcision of the Judaizing Christians. The contrast of the material and spiritual circumcision occurs elsewhere in St Paul (Rom. ii. 25-29; Col. ii. 11). The use made in the Old Testament of the image of circumcision, as a metaphor for purity, had prepared the way for the apostle's application—compare the circumcision of the heart (Lev. xxvi. 41), of the ear (Jer. vi. 10), of the lips (Ex. vi. 12, 30). At the present time the Abyssinian Church alone among Christian bodies recognises it as a religious rite. It existed among the Arabs before the time of the Prophet; and though never mentioned in the Koran, circumcision is practised with much pomp and great rejoicings in all Mohammedan populations. The Arabs in the towns of Egypt have their boys circumcised at the age of five or six; among the peasants the age varies from twelve to fourteen. A vivid account of the ceremonies is given in Lane's *Modern Egyptians*. See a paper by Paul Lafargue in the *Bulletin de la Société d'Anthropologie de Paris* (tome x., 3^e série, 1887).

Circumcision. FEAST OF, a festival in honour of Christ's circumcision, observed on 1st January in the Roman Church since about 487 A.D., and in the Anglican since 1549. See NEW-YEAR'S DAY.

Circumference, or PERIPHERY, the curve which incloses a circle, ellipse, oval, cardioid, or other plane figure. In figures bounded by straight lines, as the triangle, square, and polygon, the term *perimeter* is employed to designate the sum of all the bounding lines taken together. The length of the circumference depends partly on the nature of the curve; thus, that of the Circle (q.v.) = $2\pi r = \pi d$; and that of the Ellipse (q.v.)

$$= 2\pi a \left\{ 1 - \left(\frac{1}{2}\right)^2 \frac{e^2}{1} - \left(\frac{1.3}{2.4}\right)^2 \frac{e^4}{3} - \left(\frac{1.3.5}{2.4.6}\right)^2 \frac{e^6}{5} - \&c. \right\}$$

where a is the semi-axis major, and e the eccentricity.

Circumlocution Office, the name under which Dickens, in *Little Dorrit*, satirised the Civil Service.

Circumnavigation, the term usually applied to the act of sailing round the world, its literal meaning being simply 'a sailing round.' The circumnavigation of the globe was at one time considered a great feat, but it is now one of the most commonplace affairs in a sailor's experience. The first to circumnavigate the globe was Sebastian d'Elcano, lieutenant of Magellan (1519-22); fifteen years afterwards it was accomplished by two Spanish seamen, Grijalva and Alvaradi; and in 1577-80 by the illustrious Englishman, Sir Francis Drake. The most celebrated of circumnavigators was Captain James Cook, who, between 1768 and 1779, made three voyages round the world.

Circumstantial Evidence. See EVIDENCE.

Circumvallation. LINES OF, form a chain of works surrounding an army engaged in besieging a fortress, but facing outwards towards the country so as to guard against all attempts at relief by a field army. Redoubts, either isolated or connected by a line of parapet, were much used for this purpose in the sieges of the ancient and middle ages; but the greater mobility of modern armies makes it preferable to meet such attempts in the open field, many miles from the position occupied by the investing force. At Sebastopol, owing to the smallness of the besieging force compared with that of the besieged, an outer circuit of redoubts and lines was necessary to keep off the Russian field army, which at Inkermann

very nearly succeeded in penetrating this external defence. See CONTRAVALLATION, SIEGE.

Circus, in ancient Rome, was a large oblong building adapted for chariot-races and horse-races, and used also for the exhibition of athletic exercises, mock-contests, and conflicts of wild beasts. The Circensian Games were alleged by tradition to have originated in the time of Romulus; and Tarquinius Priscus celebrated a notable victory by games. The games continued to be held annually, and a permanent edifice was soon afterwards constructed. This was distinguished, subsequent to the erection of the Flaminian and other large circi, as the Circus Maximus. It must have been altered and enlarged at various times. Dionysius says it could hold 150,000 persons; Pliny, 260,000; and P. Victor, 385,000. Its extent also has been variously estimated. In the time of Julius Caesar it was three stadia or 1875 feet long, and one stadium or 625 feet wide, while the depth of the buildings surrounding the open space was half a stadium, or about 312 feet. The plan was oblong, rounded at one end and square at the other. Along the sides and at the curved end were ascending ranges of stone seats for the spectators. At the other end were the *carceres* or stalls in which the horses and chariots were kept, until, on a given signal, the gates were simultaneously flung open. In the centre was the *spina*, a long and broad wall round which the charioteers drove, terminating at both ends at the *metae* or goals—conical pillars which marked the turnings of the course. Julius Caesar made an *curipus* or canal round the course to protect the spectators more effectually during the conflicts of wild beasts.

The circus was especially adapted for chariot-races, an amusement of which the Romans were passionately fond. The length of a race was seven circuits round the *spina*, and twenty-five races were run in each day. The number of chariots was usually four. The athletic exercises, such as boxing and wrestling, sometimes terminated fatally. A regular battle was sometimes represented (*Pugna Equestris et Pedestris*). By the formation of canals and the introduction of vessels, a *Naumachia*, or sea-fight, was occasionally exhibited; but, under the empire, this species of exhibition, as well as the *Venatio*, was gradually transferred to the Amphitheatre (q.v.). Animals for the *Venatio* or hunting were procured from every available part of the Roman empire, including Africa and Asia. The exhibition not only afforded an opportunity for the display of private munificence or ostentation, but attained the importance of a political engine, which none who aspired to popularity could afford to overlook. The turbulent classes often demanded doles of bread and circus games (*panem et circenses*) from candidates. When Pompey opened his new theatre he is said to have given public exhibitions in the circus for five days, during which five hundred lions and twenty elephants were destroyed. The Greek *hippodrome* was very similar in its arrangements to the Roman circus.

In modern times the circus survives but as the shadow of a name. It is about the same size as the modern theatre, and is employed principally for the exhibition of feats of horsemanship and for acrobatic displays. Modern circuses are of two kinds—those that hold performances in permanent buildings, of which there are only a comparatively small number in Britain and the United States, and those that 'tent' or occupy temporary erections in spring and summer, and return to buildings in winter. A circus manager on a tour must have a plentiful supply of novelties in the shape of graceful and daring riders, conjurers, and performing horses. A stud of highly trained performing horses, often of great value, is an important feature in every

well-appointed circus. English and American equestrians are superior to those of any other nationality, and their services are eagerly sought for on the Continent, where the bulk of the performers are English. Astley (q.v.) was the most famous of English circus-managers. The Paris hippodrome is celebrated. But the circus in connection with Barnum (q.v.) and Bailey's 'Greatest Show on Earth' is probably the most important ever organised, including a whole army of performers, 'mid-air artists,' and male and female equestrians.

Cirencester, a town of Gloucestershire, amid the Coteswold Hills, on the Churn, a headstream of the Thames, and on the Thames and Severn Canal, 14 miles SSE. of Cheltenham, and 18 by rail NW. of Swindon. It has a very fine Perpendicular church (restored 1867), a public hall (1863), some remains of an abbey (1117), and, 1 mile distant, an agricultural college (1846), a Tudor edifice (see AGRICULTURE). Near this is the handsome seat of Earl Bathurst. There is a considerable trade in wool and agricultural produce, and the town is a hunting centre. Till 1867 it returned two members; till 1885 one. Pop. (1851) 6096; (1881) 7658. Cirencester (pronounced *Cisster*) was the Roman *Corinium*, at the junction of five Roman roads; and there is a good collection of Roman antiquities found in the neighbourhood. Canute held a council here in 1020. Rupert stormed Cirencester in 1642 and 1643. The early English chronicler Richard (q.v.) of Cirencester was a native.

Cirrhosis, the drunkard's liver. See LIVER, ALCOHOLISM.

Cirripedia (Gr., 'curl-footed'), a degenerate sub-class of Crustacea, including the numerous forms of Barnacles and Acorn-shells (q.v.). *Cirrhopoda* was a form of the name once commonly in use.

Cirrus. See CLOUDS.

Cirrus, CIRRHUS, in Botany, see TENDRIL, CLIMBING-PLANTS. The term cirrus, in Zoology, may designate any curled filament, and has been applied to the curiously modified abdominal limbs of the Cirripedia (q.v.).

Cirta, the capital of ancient Numidia, now Constantine (q.v.).

Cis, a Latin preposition, meaning 'on this side' (as opposed to *trans* or *ultra*, 'beyond'), which is often prefixed to names of rivers and mountains to form adjectives; Cisalpine, Cispadane, 'on this side of the Alps,' 'of the Po.' As most of these words are of Roman origin, Rome is usually the point of view; but in Ultramontane (q.v.) it is otherwise, as also in Cisleithania, a division of the Austrian dominions—see AUSTRIA, Vol. I. p. 595.

Cisalpine Republic. After the battle of Lodi, in May 1796, General Bonaparte proceeded to organise two states—one on the south of the Po, the Cispadane Republic, and one on the north, the Transpadane. These two were on 9th July 1797 united into one under the title of the Cisalpine Republic, which embraced Lombardy, Mantua, Bergamo, Brescia, Cremona, Verona, and Rovigo, the duchy of Modena, the principalities of Massa and Carrara, and the three legations of Bologna, Ferrara, and the Romagna. The republic had a territory of more than 16,000 sq. m., and a population of 3½ millions. Milan was the seat of the government or Directory. The army consisted of 20,000 French troops, paid by the republic. The republic was dissolved for a time in 1799 by the victories of the Russians and Austrians, but was restored by Bonaparte after the victory of Marengo, with some modifications of constitution and increase of territory. In 1802 it took the name of the

Italian Republic, and chose Bonaparte for its president. A deputation from the republic in 1805 conferred on the Emperor Napoleon the title of King of Italy; after which it formed the kingdom of Italy till 1814. See ITALY.

Cissampelos, a genus of Menispermaceæ, of which one species, *C. Pareira*, was formerly regarded as the source of the drug known as *Pareira Brava* (q.v.), also called *Butua Root*.

Cissoid (Gr., 'ivy-like,' from the shape), a plane curve consisting of two infinite branches symmetrically placed with reference to the diameter of a circle, so that at one of its extremities they form a Cusp (q.v.), while the tangent to the circle at the other extremity is their common asymptote. It was invented by Diocles of Alexandria to solve the problem of finding two mean proportionals; but Newton first showed how to describe the curve by continuous motion. The area included between the two branches and the asymptote is exactly equal to thrice the generating circle. In later times the term has been generalised to comprise higher curves described by the same law, but where the generating curve is not a circle. When the asymptote is vertical, the circular cissoid seems to

grow towards it as ivy does to a wall, &c. Draw any straight line AB to the tangent. Measure AO = BC, and thus O traces the curve.

Cissus. See VITACEÆ.

Cis-Sutlej States, a term first given to the Sikh principalities which arose south of the Sutlej in the end of the 18th century, and now includes the British districts of Unbala (Ambala), Ludhiana, Ferozpur, Hissar, and the native states of Patiala, Jind, and Nabha.

Cist. See COFFIN, BARROW, BURIAL.

Cistercians, a monastic order founded by the Benedictine abbot Robert of Champagne, in France, who, after repeated attempts—at first in the forest of Molesme—at a reformation of the secularised monastic life, established in 1098, in the forest of Cîteaux (Cistercium), a small hamlet near Dijon, along with twenty companions, a monastery for the purpose of carrying out the strictest observance of the rule of St Benedict. By command of the pope Robert returned in 1099 to Molesme, where he died in 1108; but his successor, Alberic (who died in 1109) succeeded in gaining the pope's favour and the confirmation of the order, and drew up the *Instituta Monachorum Cisterciensium*, which represented the new foundation as the only true Benedictinism. His successor, Stephen Harding, ruled in the same spirit, and still further stamped the order with its distinctive character of austerity. Yet Cîteaux was near extinction when the famous St Bernard, together with thirty companions, joined the Cistercians in 1113. Two years afterwards he became the first abbot of Clairvaux, which thenceforward was the centre of the influence he wielded throughout Europe. In 1119 the Abbot Stephen issued a new rule, the 'Charter of Charity,' for the monks of the order, which was already augmented by two additional monasteries. It gained great accessions in Spain and Portugal, as well as in France, where the Cistercians now also bore the name of Bernardines. Before the end of the 12th

century the order had 800 abbeys in different countries of Europe, and by the middle of the 13th its establishments had reached the number of 1800. But as riches increased, the old austerity and unity decayed; the Spanish abbots seceded, and even in France and Italy arose separate congregations, such as the Feuillans and the Trappists. The Cistercians did little for the progress of the sciences; but they rendered valuable service in the development of agriculture, and in the 12th and 13th centuries they were consistent promoters of Gothic architecture.

The Cistercians were distinguished from the order of Clugny (q.v.) by their severer rule and stricter poverty, avoiding everything like splendour in their churches, even gold and silver crosses; by being submissive to the jurisdiction of the bishops, at least till after the death of St Bernard; by not meddling with the cure of souls; by wearing a white robe with a black scapulary; and by their peculiar form of government, which was introduced by Innocent III. in 1215 into all the monastic orders. In England their earliest establishment was Waverley Abbey (1128), near Farnham, in Surrey. The number of Cistercian abbeys in England in the reign of Henry VIII. was 75, besides 26 Cistercian nunneries. In Scotland there were 11 abbeys and 7 nunneries. Among the English abbeys were Woburn, Tintern, Furness, Fountains, Kirkstall, and Rievaulx; among the Scottish, Melrose, Dundrennan, Kinloss, Glenluce, Culross, Deer, Balmerino, and Sweetheart or New Abbey. The chief French abbeys, 'the four eldest daughters of Cîteaux,' as they were called, were La Ferté, Pontigny, Clairvaux, and Morimond, the last of these having itself 700 dependent benefices. Port Royal des Champs was the most celebrated of the Cistercian nunneries. Riches and indolence brought this powerful order, as well as others, into decay. Even before the Reformation many of their convents had ceased to exist. The French Revolution reduced the Cistercians to a few convents in Spain, Poland, Austria, and Saxony. The last remnant of the order in France was expelled in 1880. At Mount St Bernard, near Coalville, Leicestershire, they have a 'mitred' abbey built

by Pugin the elder. See Manriquez, *Annales Cistercienses* (4 vols. Lyons, 1642); *The Cistercian Saints of England* (ed. by Newman, 1844); Sharpe, *The Architecture of the Cistercians* (1874); Janauschek, *Origines Cisterciensium* (1877); also the articles BENEDICTINES, MONACHISM.

Cistern. See WATER-SUPPLY.

Cistus (Gr.), or ROCK-ROSE, a genus of thalamifloral dicotyledons, which gives its name to the Cistaceæ, an order allied to Crucifereæ and Capparideæ, and containing about four genera and sixty species of shrubs and herbs, chiefly Mediterranean. Many

twigs of some species of *Cistus*, natives of southern Europe and the Levant, particularly *C. creticus*, *C. cypricus*, and *C. ladaniferus*, the resinous substance called *Ladanum* is obtained, which is used as a stimulant, chiefly in plasters, but has become obsolete in modern medical practice. Many species of *Cistus* are much cultivated for the beauty of their large wild-roselike flowers, which are red, white, lilac, yellow, or frequently of two colours. Most of the larger kinds require in Britain some protection in winter. The common yellow Rock-roses of our dry hillsides are species of *Helianthemum*, chiefly *H. vulgare*. Many pretty varieties of this and other species are grown in gardens, especially on rock-work. Several kinds are North American.

Citation, the act of calling a party into court to answer to an action, to give evidence, or to perform some other judicial act. In England the term citation is applied particularly to process in the spiritual, probate, and matrimonial courts. In Scotland, a citation is given in the Court of Session by an officer of court, or by a Messenger-at-arms (q.v.), under authority either of a summons passing the Signet (q.v.), or of a warrant by the court. Where no messenger-at-arms is resident in the district, it may be done by a sheriff-officer. Citation is made either personally, by delivery of a copy of the warrant to the party cited; or at the dwelling-place, when the party cannot be found in person. There must be one witness in every case, and in the case of poindings two witnesses to the execution of a warrant of citation. Parties resident out of Scotland, and tutors and curators of minors, are cited edictally—i.e. by delivery of the warrant at the office of the Keeper of Edictal Citation at the General Register House in Edinburgh. The officer who executes the citation returns a certificate, called the *Execution*, of the manner in which it has been done. A new form of citation was introduced by the Citation Amendment Act of 1882, by which any officer authorised under the older law, or any enrolled law-agent, may execute a warrant of citation, by sending a registered letter to the known residence or place of business of the person to be cited, containing a copy of the summons or other document to be served with the citation subjoined.

In criminal cases the party cannot appear voluntarily in court; he must be cited, and can plead any omission in form, which cannot be obviated even by consent. This form of citation is regulated by the Criminal Procedure (Scotland) Act, 1887. Under this act the sheriff-clerk, for cases in the Sheriff Court, and the clerk of justiciary, for cases in the High Court, issue warrants in the form of a schedule appended to the act. Service of the indictment and citation on these warrants may be made by any macer, messenger-at-arms, sheriff-officer, or officer of police at any place. When the accused is in prison, it may be made by a governor, deputy-governor, or warder of the prison.

Citharon. See ATTICA.

Cithara (Gr.), an ancient instrument closely resembling the Guitar (q.v.). See also ZITHER.

Citizen. See CITY.

Citric Acid, $H_3C_6H_5O_7$, is the acid to which lemon and lime juice owe their sourness. It also occurs, in some cases along with tartaric acid, in oranges, cherries, currants, gooseberries, and other fruits having a subacid taste. For practical purposes it is always obtained from lemon, lime, or bergamot juice, which contain it in large quantity. The first named of these contains from 20 to 40 grains of citric acid in each fluid ounce.

Citric acid is prepared from these juices by a very simple process. The juice having been heated to the boiling-point to clarify it from albumen, mucilage, &c., is mixed with chalk, $CaCO_3$, which,

Common Rock-rose
(*Helianthemum vulgare*).

species are more or less resinous; and from the

combining with the citric acid, falls to the bottom as citrate of calcium. The supernatant liquid being drawn off, sulphuric acid is added to the precipitate, decomposing it, with the formation of citric acid and sulphate of lime, CaSO_4 . By crystallisation it may be obtained pure in the form of colourless, odourless prisms, which effloresce in dry air, and possess an agreeable acid taste and an acid reaction. It is readily soluble in water and alcohol, but almost insoluble in ether and chloroform. A solution of it in water cannot be kept owing to its tendency to ferment. Dissolved in syrup it keeps much longer, and is used largely in the manufacture of lemonade and other aerated beverages, communicating an acid, fruity taste. When heated, the crystals melt, then decompose, and are finally reduced to a combustible form of charcoal. In addition to its employment as a flavouring agent it is largely used in the manufactures. Calico-printers employ it for discharging the mordant from the cloth in patterns, and it is used in dyeing silk with safflower, &c.

Citric acid may also be prepared artificially, but the process is too complex ever to come into practical use. Chemically it is of great interest as exemplifying that as soon as the chemical constitution is known there is a possibility of producing the substance artificially. There is a popular idea that some day quinine, morphia, and other natural products will be formed by the random mixing together of chemicals in the chemist's beaker, but the first step towards this result must be the knowledge of their constitution, to be followed by a series of careful experiments.

Citric acid is a powerful tribasic acid (see ACIDS), and the solution in water readily dissolves zinc and iron. It forms a class of salts called Citrates, many of which are employed in medicine.

The so-called *Citrate of Magnesia*, a granular substance, which effervesces on the addition of water, and is very popular as a gentle aperient, is not really a citrate at all, but consists of a mixture of tartaric and citric acids, bicarbonate of soda, and sugar, with perhaps a trace of some magnesium salt to justify the name. The granulating is effected by mixing the powders and placing them in a pan heated by steam, when, in proportion to the citric acid present, the powders run together into a pasty mass. This is forced through a coarse riddle, and the granules are dried by a gentle heat.

Citrate of Potash, $\text{K}_3\text{C}_6\text{H}_5\text{O}_7 \cdot \text{H}_2\text{O}$, is prepared by neutralising citric acid with bicarbonate of soda. It forms a white, granular, deliquescent powder, which acts as a cooling diaphoretic in cases of fever. Dissolved in lemon-juice it is of much value in rheumatism. It is given in doses of 20 to 30 grains.

Citrate of Ammonia can only be obtained in solution, as when this is evaporated decomposition takes place and ammonia escapes. It is employed, like the potash salt, in febrile diseases.

Citrate of Iron and *Citrate of Iron and Quinine* are but examples of a large number of compounds obtained in the form of brown or greenish-brown scales which are largely used in medicine. In these the medicinal value lies not in the citric acid, but in the iron or quinine with which it is associated, although the acid has doubtless a subsidiary action. A peculiarity about these 'scale preparations,' as they are called, is that the inky taste, so characteristic of iron in the form of steel drops, is in great measure removed. Citric acid also forms a series of organic salts called citric ethers, of which citrate of ethyl is an example. Lemon-juice, in which citric acid is the most active ingredient, is a most valuable medicine in scurvy, and when it cannot be obtained the acid may be used as a substitute. Citric acid in solution does not, however, appear to be nearly so effective as the juice itself.

Citron (*Citrus medica*), a tree cultivated in the south of Europe and other warm temperate or subtropical countries for its fruit; a native of northern India. By many botanists the lemon (*C. Limonium*), the lime (*C. Limetta*), and the bergamot (*C. Bergamea*) are reckoned varieties; but it at any rate avoids confusion to describe these separately. The fruit is large, warty, and furrowed. The pulp is acid and cooling, and is used in the preparation of syrups, lemonade, &c.; but the part chiefly valued is the thick and tender rind, which has a delicious odour and flavour, and is preserved or candied. From this also the fragrant Oil of Citron, or Oil of Cedrate, used by perfumers, is procured. In Germany the name cedrate is

Citron (*Citrus medica*):
a, fruit; b, transverse section of fruit.

extended to all kinds of citron, and the name citron is usually given to the lemon. The fruit of the largest kinds (var. *macrocarpa*) sometimes weighs 5 lb. In the United States the name citron is applied to different varieties of the melon, especially one resembling the water-melon, but edible only when made into preserves or pickles. It is probable that the citron is meant in some passages of the Old Testament where the word apple is used in the English version.

Citronwood, or CITRUS-WOOD, the most costly furniture-wood of Roman antiquity, is usually regarded as derived from *Biota* (*Thuja*) *orientalis*, or possibly from *Callitris quadrivalvis*, allied coniferous trees, both popularly known as *Arbor Vitæ* (oriental and African). Cicero is said to have paid an enormous sum for a table of this wood.

Citrus, a genus of Aurantiaceæ (q.v.), trees and shrubs of tropical, subtropical, and warm temperate Asia, but many of them now cultivated in all similar climates for their fruit. To it belong the Orange, Citron, Lemon, Lime, Bergamot, Shaddock, Forbidden Fruit, &c.

Città di Castello, a town of Central Italy, on the Tiber, 25 miles NNW. of Perugia. It has a castle, a cathedral, and several palaces rich in works of art. In the church of Santa Trinità is preserved Raphael's first commission, a guild-banner. Pop. 5433.

Cittavecchia. See MALTA.

City (Fr. *cité*, Lat. *civitas*). In the sense in which it was first used in the Romanic languages of modern Europe, the word *city*, like its Latin original, was probably equivalent to state (*res-publica*) rather than to town or borough (*urbs, municipium*). This usage may be contrasted with

that of the Greek term *polis*, which, originally denoting merely a town or collection of households, came afterwards to be frequently used as synonymous with *politeia*, a state or free community. Perhaps the nearest example in the present day to the city in the above sense is to be found in such of the cantons of Switzerland as consist chiefly of a town and its surroundings, for example, Geneva. It is difficult to find any precise meaning attached to the word city in medieval times. In his glossary of medieval Latin terms Ducange defines *civitas* as *urbs episcopalis*, that is, a town in which there exists an episcopal see; but this restricted use of the word, though commonly accepted, rests on no sufficient ground (see CATHEDRAL). It would seem in fact that from a very early period in English history towns have been denominated either *civitas*, *villa*, or *burgum*, and the inhabitants thereof *cives*, *homines*, and *burgenses*, indifferently. Thus in Domesday Book we find mention of the city (*civitas*) of Norwich, of Exeter, and of Coventry, but town of Ipswich, of Bedford, and of Shrewsbury; while Gloucester and Leicester are styled both city and borough (*burgum*).

In its modern sense the term city, as used in the United Kingdom, is generally applied to all towns which are incorporated, and which either are or have been sees of bishops. See BOROUGH.

In the United States, a city is an incorporated town, invested with the highest municipal privileges and duties. In some states, 10,000 inhabitants are requisite to the formation of a city government, while in the new states a less number is required. A city has power to legislate upon local matters pertaining to it in accordance with the provisions of its charter, granted by the sovereign power of the people through the legislature of a state. In several of the Western States cities are organised under a general law, all having over 15,000 inhabitants being designated cities of the first class; under 15,000 and over 2000, cities of the second class; and all villages with less than 2000, cities of the third class.

In the case of towns which have grown greatly beyond their original dimensions it is not unusual to give the name of city to the space which they originally occupied—thus, we speak of the City of London, in contradistinction to the metropolis, *la Cité* of Paris, and similarly of other places.

A citizen (Fr. *citoyen*, Lat. *civis*) is defined by Aristotle to be one to whom belongs the right of taking part both in the deliberative, or legislative, and in the judicial proceedings of the community of which he is a member (*Politics*, iii. 1). A citizen, therefore, can exist only in a free state. Between a citizen and a subject there is this distinction, that whilst the latter merely is governed, the former also governs; and thus, though every citizen is a subject, many subjects are not citizens. At first the rights of citizenship in Athens and other Greek communities were readily attained by those who were not born to them; but at a later period, when the organisation of Greek civic life had reached a high degree of perfection, admission to the roll of citizens was procured with great difficulty. In Rome, under the early law, there were perfect and less perfect citizens; that which peculiarly distinguished the higher class was the right to vote in a tribe, and the capacity of enjoying magistracy. All the private rights of citizenship (the *jus connubii* and *jus commercii*) belonged to the citizens of the lower class. Under these two classes, again, there were two others, originally aliens—the Latini and the Peregrini.

Roman citizenship was acquired most commonly by birth, but for this it was requisite that both father and mother should be citizens. If a citizen married a Latina or a Peregrina, even believing

her to be a citizen, the children begotten of the marriage followed the status of the mother. In the earlier days of the republic, citizenship could be conferred on a stranger only by means of a *lex*—i.e. by a vote of the people assembled either in one or other of the Comitia. When the imperial power was established, however, the public rights which formed the chief characteristic of the full Roman citizenship became little more than empty names; and the only value which thenceforth attached to it consisted in the private rights which it conferred. St Paul was 'free-born'—i.e. born a citizen. Such as it was, the constitution of Caracalla extended it to the free inhabitants of the whole Roman empire, and under Justinian the only divisions of subjects thenceforth was into citizens and slaves.

In France, during the Revolution, the word citizen was adopted by the republicans as the most appropriate term to express the grand principle of *liberté, égalité, et fraternité*. It took the place of *Monsieur*. Every Frenchman became *Citoyen* in relation to other Frenchmen, the highest in official station being so addressed by the lowest. The usage gradually died out after the assumption of imperial power by Napoleon. In its modern use, the term citizen is applied in Britain and elsewhere either specifically to a dweller in a town, or to any one who is either born in the country or has become legally naturalised in it.

In the United States, the words 'citizens' and 'people' are synonymous terms. From the point of view of American constitutional law, a citizen being a member of the political community to which he belongs, every person born in the United States and subject to its jurisdiction falls within the definition. An alien may become a citizen by being naturalised under the Acts of Congress. Again, a citizen of the United States residing in any state of the union is a citizen of that state. There being a government in each of the several states, as well as a government of the United States, a person may be at the same time a citizen of both, but his rights as a citizen under one of these governments differ from those under the other. Thus, although the government of the United States is supreme and paramount to the states, it cannot secure to the citizen rights or privileges which are not placed under its jurisdiction by the constitution. (On the other hand, a person may be a citizen of the United States and not be a citizen of any particular state, having his residence in one of the territories, or not having a fixed residence in any state.)

Citizens of each state are entitled to all privileges and immunities of citizens in the several states, and citizens of all other states have the right to go into any state and carry on business, to hold property and be protected like the citizens of that state in their rights. It may further be observed that under the existing constitutional law, children born of Chinese parents are citizens of the United States, but Chinese aliens are incapable of becoming citizens. See NATURALISATION, ALIEN, BOROUGH; and Fustel de Coulanges, *La Cité antique* (1864).

City of Refuge. By the Jewish law with regard to unintentional manslaughter, indicated in Exod. xxi. 13, and fully set forth in Num. xxxv., Deut. xix., and Josh. xx., the parts of Palestine to the west and east of the Jordan were each divided into three districts, and in each district was a city in which the manslayer should at once with all speed seek refuge. If the elders of the city of refuge recognised the manslayer's claim to the right of asylum, he was provisionally secure from the *goel* or avenger. He was then set before the community (represented by its elders) in the midst of which the deed was done, that they might decide judicially whether the right of asylum should be further extended

to him. In that event he was free to return and sojourn in the city of refuge; and afterwards, if the goel found him outside it, he had a *right* (though not the *duty*) to kill him. Not till the death of the high-priest was he at liberty to return home. See BLOOD (AVENGER OF); and for the usage in other countries, see SANCTUARY.

Ciudad Bolívar. See ANGOSTURA.

Ciudadela, a seaport town (formerly capital) of the island of Minorca, on the west coast, with a cathedral, ruined fortifications, and exports of cattle, wool, cheese, and building-stone. Pop. (1878) 7777.

Ciudad Real ('royal city'; *Ciudad* being Lat. *civitas*), a town of Spain, capital of the province of the same name—area, 6042 sq. m.; pop. (1885) 280,642—situated on a plain between the rivers Guadiana and Jabalon, 105 miles S. of Madrid by rail. It is a poor, dull place, but has a fine Gothic church, and remains of the old town-walls, with one handsome gateway. There are manufactures to a small extent of coarse woollens, linen, and table-cloths, and a trade in the agricultural produce of the district. Pop. (1877) 13,589; (1885) 13,365.

Ciudad Rodrigo ('Roderic's Town'), a fortified town of Spain, 17 miles from the Portuguese frontier, and 56 SW. of Salamanca by rail, on a steep hill above the river Agueda, which is here crossed by a fine bridge. It is a poor, dirty town, with a Gothic cathedral. It was taken by the English (1706) and French (1707) in the War of the Spanish Succession, but is chiefly of interest for its sieges during the Peninsular war. In the spring of 1810 the French under Massena invested the town, and after a gallant defence by the Spaniards, it was forced to surrender on the 10th July. Meanwhile Wellington was gaining time to strengthen his lines at Torres Vedras; and in January 1812 he pounced down on Ciudad Rodrigo, and after a siege of eleven days, took the place by assault. For this brilliant achievement he was created an English earl, and, by the Spanish Cortes, Duke of Ciudad Rodrigo. Pop. 6856.

Civet (*Viverra*), a genus of cat-like carnivores. Besides several species of *Viverra* proper, there are sundry other closely related forms, such as the *Genettes*, which some regard as separate genera.

Civet.

The long, thin body, the pointed head, the short legs, and small hairy feet are external characteristics. The larger species, such as the two first named below, are rather larger than a fox, but the *Viverricula*, the *Genettes*, &c. are often decidedly smaller. They are active and fierce carnivores. The civets are best known in connection with the strong perfume obtained from two (per-

ineal) glands near the anus. Such glands are common enough: it is only their penetrating fragrance which is peculiar. The civet perfume of commerce is obtained from *V. civetta*, the African civet or civet cat; from *V. zibetta*, the Indian civet of Bengal, China, and the Malayan region; from *V. tangalunga*, similar in distribution to the last; and from *Viverricula malaccensis*, the Rasse of India, China, Java, and Sumatra. Civets are often kept in confinement for the sake of the perfume, which is removed from the glands about twice a week by means of a small spatula, and is obtained most abundantly from the male, especially after he has been irritated. A dram is a large quantity to obtain at a time. Abyssinia is one of the principal seats of the trade, and Java another. The perfume is most used in the East.

Civil Damage Acts, passed in several of the United States, giving to husbands, wives, children, parents, guardians, employers, and others who have sustained injury in person or property or means of support, by any intoxicated person in consequence of such intoxication, the right of action against the person who sold or gave away the liquor which caused such intoxication, have been held to be constitutional. In some cases the right of action has been extended to the owner of the premises where such intoxicating liquor has been obtained.

Civil Death. See DEATH (CIVIL).

Civil Engineer. See ENGINEER.

Civilian is either a person whose pursuits are civil—i.e. neither military nor naval; or one who is skilled in the civil law—a student, professor, or doctor of the Roman civil law.

Civilisation. See ANTHROPOLOGY, ARCHÆOLOGY, ART, GOVERNMENT.

Civil Law. See LAW.

Civil List. Down to the period of the Restoration in 1660, notwithstanding an attempt at negotiation between James I. and the parliament for the commutation of the hereditary revenues of the crown, the whole expenses of the government of England, civil and military, were included in one list, or rather they were defrayed out of what was called the royal revenue. This revenue, which arose partly from crown-lands, partly from the hereditary excise and other hereditary revenues, and partly from the ordinary excise, was for a long period after the Conquest really at the disposal of the crown. Even after the supplies were provided by parliament, the specific mode of their expenditure continued to be free from parliamentary control. But at the Restoration a distinction was made (by statute 12 Charles II.) between the extraordinary expenses occasioned by war, and the ordinary cost of the civil establishments of the country. For the latter the needful funds were provided, partly from such crown-lands as were still unalienated, and partly from taxes which parliament voted for the purpose at the commencement of each reign. These were called the hereditary or civil list revenues, the amount of which was in 1689 fixed at £600,000 per annum. During the reign of William III. the civil list was twice raised, and in 1698, after the war with France, stood at £700,000. To provide the additional sum a new subsidy of customs was granted to the king for life. The branches of expenditure included under this head were the following: (1) The royal household; (2) the privy purse; (3) the royal palaces; (4) the salaries of the chancellor, judges, great officers of state, and ambassadors; (5) the incomes given to the other members of the royal family; (6) the secret-service money, pensions, and other irregular claims. The support of the army and navy was,

however, provided for by an annual vote of the House of Commons, and the interest of the national debt was never charged against the civil list. During Queen Anne's reign matters remained nearly on their former footing; the civil list remaining at £700,000, provided for out of the excise on liquors, the new subsidy of customs of 1698, and the land revenues of the crown. This was also the amount during the reign of George I., but on the accession of George II. it was raised to £800,000; and again in the fifty-fifth year of the reign of George III. it had to be further raised to £1,030,000. George III. surrendered some portions of the hereditary revenue of the crown which had been retained by his predecessors, and the annuities to members of the royal family were now paid out of the Consolidated Fund (q.v.) to the amount of £280,000. When George IV. succeeded to the throne, £255,000 of expenditure was transferred to other funds, and the civil list was fixed at £850,000 per annum. The crown enjoyed, in addition, the hereditary revenue of Scotland, amounting to about £110,000, and a separate civil list was kept up for Ireland of £207,000. Against these large sums, however, were still placed many charges which belonged to the nation rather than the crown; and it was not till the 15th November 1830 that Sir Henry Parnell, afterwards Lord Congleton, carried a motion for the appointment of a select committee for the purpose of separating the proper expenses of the crown from all other charges. The result of this measure was the act, 1 Will. IV. c. 25, for the regulation of the civil list. The sum of £510,000 was in 1831 granted to his majesty, and exclusively devoted to the privy purse, the salaries and expenses of the royal household, secret-service money, and pensions. The separate list for Ireland was discontinued, and the Scotch hereditary revenues and other items were directed to be paid into the Exchequer. The change was rather a redistribution, which enabled the country to look more closely into its expenditure, than a real reduction of the civil list.

On the accession of Queen Victoria, the civil list, which had long been of the nature of a permanent compact between the monarch and the parliament, and as such beyond the control of parliament during the life of the sovereign, was settled by 1 and 2 Vict. chap. 2. The Queen surrendered the hereditary revenues of the crown for life, in consideration of a yearly sum of £385,000, charged against the Consolidated Fund, to be devoted solely to the support of Her Majesty's household, and the honour and dignity of the crown. The application of this sum was intrusted to the Lords of the Treasury, who were directed to pay yearly (1) to the Queen's privy purse, £60,000; (2) salaries and expenses of the royal household, £231,260; (3) retiring allowances and pensions to officers, &c. of the household, £44,240; (4) for royal bounties, alms, and special services, £36,300; (5) general expenditure of the court, £13,200. This sum of £385,000 does not include the annuities of £40,000 per annum to the Prince, and £10,000 per annum to the Princess of Wales, nor the other grants made by special acts of parliament to members of the royal family. It is provided that if the civil list charges in any one year shall exceed the total sum of £400,000, an account of the particulars of excess shall be laid before parliament in thirty days. Besides the above sum, Her Majesty was accorded the right of granting new pensions, to the amount of £1200 every year, 'to persons who have just claims on the royal beneficence, or who, by their personal services to the crown, by the performance of duties to the public, or by their useful discoveries in science, and attainments in literature and the arts, have merited the gracious

consideration of their sovereign and the gratitude of their country.' These pensions amount to about £25,000 per annum, so that the gross sum allotted to the civil list every year is now about £410,000.

Civil Service. Under this head are classed all officers of the crown who do not belong to the military or naval services, and are engaged in the administration of the civil affairs of the state, such as the collection of the revenue, the administration of law and justice, the performance of the executive duties of the government, and the representation of the country abroad. Originally the civil service was a body small in number and personal to the sovereign, but with the growth of popular control over state affairs, the number of persons employed under government has vastly increased, and there have been many new departments called into existence to carry out fresh laws. For instance, the Education Department was established to administer the grants made by parliament in aid of public education, the Poor-law Commission for the administration of the Poor-laws, and the Board of Trade for the purpose of carrying out new laws relating to shipping and railways. Posts in the civil service were originally in the gift of the ministers of the crown, and no qualifying test was applied, though in some departments tests of competency were applied by the authorities at their sole discretion to candidates for clerkships. Amongst these departments were the Admiralty, the Audit Office, the Customs, the Excise, the General Register Office, the National Debt Office, the Ordnance Office, the Pay-office, the Post-office (London), the Stationery Office, the Treasury, and the War Office. But no examination whatever took place on appointment to some of the most important offices of the state, such as the Home Office, the Foreign Office, the Colonial Office, the Board of Trade, the Office of Works, or the Office of Woods. The inadequacy of these arrangements having been forcibly pointed out in 1853 in a report by Sir Stafford Northcote and Sir Charles Trevelyan, an order in council which was issued in 1855 directed that tests of fitness should be insisted upon as regards all junior situations in all departments of the civil service, and that such tests should be applied by a separate and independent board created for the express purpose.

A Board of Commissioners was appointed, and entered at once upon its duties. Some time, however, was required to bring under the new system all the situations and employments which it was intended to affect. Not the least important of the tests were directed to the proof of a candidate's fitness in respect of age, health, and character. The Superannuation Act, 1859, made the grant of certificates by the Commissioners an essential condition, in ordinary cases, to the receipt of a pension. In the earlier years of the Commission its proceedings were almost exclusively concerned with the examination of candidates nominated singly to single posts, the only question to be decided being whether the candidate reached or did not reach a minimum standard of competency. There was no rule providing for competition either open or limited. On the other hand, there was nothing to preclude competition if those who had the power of appointment to any situation should choose to nominate several candidates for one vacancy, or to invite applications from the public at large. The average ratio of nominees to places was about three to one. But, as many of the nominees failed to reach the minimum standard, the proportion of competent or effective candidates was lower, sometimes not more than one to one, a result of course inconsistent with the idea of competition. To remedy this defect

it was arranged in 1861, on the recommendation of a select committee of the House of Commons, that persons nominated to clerkships in the gift of the Treasury should first be subjected to a test examination of an elementary character, and that those who passed this test should afterwards compete in the proportion of three candidates to a vacancy. In 1870 the plan was superseded, as far as regards these clerkships, by open competition. Limited competitions have, however, continued for various situations in respect of which the heads of departments retain the right of nomination. It was not until some years after the promulgation of the order of 21st May 1855 that the experiment of entirely open competition was tried. The first absolutely open competition occurred in 1859, when, at the instance of the then Secretary of State for India (Lord Derby), 339 candidates, having offered themselves in answer to public advertisement, were examined for eight writerships in the India Office. The advantages of open competition were formally recognised by a resolution of the House of Commons on 24th April 1856, as well as by a select committee of that House which sat in 1860.

The general application of the principle of open competition to the home civil service dates from the order in council of 4th June 1870, which laid it down as to certain specified departments comprising the bulk of the service that open competition for clerkships and similar situations, instead of being, as before, permissible at the discretion of the heads of departments, should thenceforth be the rule, unless expressly excluded. From that date to the present time the field of open competition has been continually extending, and it now includes several departments which, though not necessarily subject to the rule, have thought fit voluntarily to accept it. From May 1855 to June 1870 the number of competitors was 1594 for 37 appointments; and from June 1870 to December 1885 there were 108,400 competitors for 14,717 appointments. Persons seeking appointments in the civil service which are open to competition must pass either (1) a special examination arranged to suit the class of appointment; (2) the Class 1 examination, which is generally known as the Higher Division; or (3) the Lower Division examination. From 1870 to 1876 appointments to the clerical staff were, except in a few special cases, divided as regards examination into Class 1 and Class 2, the former of which still continues. The latter was, however, superseded after the report of a Royal Commission over which Sir Lyon Playfair presided, by the examination for the Lower Division of the service which was constituted by order in council of 12th February 1876. This order provided that no department throughout Her Majesty's civil service shall be permanently increased or regulated afresh without providing for the introduction of a system whereby such of its duties as are of a suitable character shall be performed by members of the Lower Division. The intention of this was to reduce the cost of the clerical staff in the various departments. After the system had been in force a few years it gave rise to much agitation among the clerks, and eventually a Royal Commission was appointed in 1886 to inquire into the whole administration of the service. In September 1888 the Commission presented its report on the working of the Playfair scheme, and on the scales and regulations under which pensions are granted. It recommended that the service should be divided into 'First Division' and 'Second Division' to take the place of the Upper and Lower Divisions of the Playfair system; the salaries of the 'First Division' to begin at £200 and to rise to £1000 a year, and those of the 'Second

Division' to begin at £70 and to rise to £350 a year. The entire civil service was to be placed on these scales so as to secure uniformity and to facilitate transfers from one department to another. The Commissioners recommended a revision of the pension system with a view of compelling civil servants to make some contribution towards their pensions, and they suggested a deduction of 5 per cent. from salaries for this purpose. These recommendations of the Commission can, however, only take effect when the law is altered and fresh orders in council are issued.

At the census of 1881 there were 50,245 persons employed in the civil service, of whom 25,568 were officers and clerks, 21,180 office-keepers, messengers, porters, and letter-carriers, and 3497 prison officers. Of these 50,245 persons, 45,892 were males and 4353 were females. Appointments in the civil service as a rule are held for life, and confer the right to a pension. The pension system was instituted by the Superannuation Act, 1859, which provides that the superannuation allowance to be granted to persons who shall have served in an established capacity in the permanent civil service of the state, whether their remuneration be computed by day pay, weekly wages, or annual salary, and for whom provision shall not otherwise have been made by act of parliament, or who may not be specially excepted by the authority of parliament, shall be as follows: To any person who shall have served ten years and upwards and under eleven, an annual allowance of ten-sixtieths of the annual salary and emoluments of his office; for eleven years and under twelve years, an annual allowance of eleven-sixtieths of such salary and emoluments; and, in like manner, a further addition to the annual allowance of one-sixtieth in respect of each additional year of such service until the completion of a period of service of forty years, when the annual allowance of forty-sixtieths may be granted, and no addition shall be made in respect of any service beyond forty years. Special allowances are made in cases of the abolition of office, and these are entirely in the discretion of the Commissioners of the Treasury. By the Pensions Commutation Act, 1871, pensions may be commuted by persons entitled to them according to a scale which has been fixed by government.

In the public accounts of Great Britain the Civil Service Estimates fall under the heads of: (1) Public Works and Buildings; (2) Salaries and Expenses of Civil Departments; (3) Law and Justice; (4) Education, Science and Art; (5) Foreign and Colonial Services; (6) Non-effective and Charitable Services; (7) Miscellaneous. For the public accounts, see GREAT BRITAIN; and for the Indian Civil Service, see INDIA.

CIVIL SERVICE OF THE UNITED STATES.—In January 1883 Congress passed a law to prevent the abuse of the appointing power of the officers of government. The President was authorised to appoint, with the advice and consent of the Senate, three Civil Service Commissioners, whose duty is to aid the President in preparing suitable rules which shall provide for open competitive examinations for testing the fitness of applicants for the public service, such examinations to be practical in their character, and so far as may be relating to those matters which will fairly test the relative capacity and fitness of the persons examined to discharge the duties of the service. All the offices, places, and employments arranged in classes or grades are to be filled by selections according to grade from among those graded highest as the results of such competitive examinations. The appointments to the public service in the departments at Washington are to be proportioned upon the basis of population to the several states and

territories and the District of Columbia. The law provides a period of probation before any absolute appointment is made, and exempts all persons in the public service from all obligation to contribute to any political fund or to render any political service. It forbids any person in the public service using his official authority to coerce the political action of any other person or body. Non-competitive examinations in all proper cases are provided for after notice given of a vacancy, the appointing power to give notice in writing to the Civil Service Commission of the persons selected for appointment among those who have been examined. Power is given this Commission to make regulations for, and to have control of, such examinations, subject to the rules made by the President. The Civil Service Commission is required to report annually to the President, for transmission to Congress, its own action, the rules and regulations, and the exceptions thereto in force, the practical objects thereof, and any suggestions for the more effectual accomplishment of the purposes of the law. Provision is made for holding examinations at convenient places twice each year in every state and territory of the United States.

The Commission punishes by fine and imprisonment all in the public service who wilfully defeat, obstruct, or deceive any person in respect to his or her right of examination, or who shall corruptly and falsely mark, grade, estimate, or report upon the proper standing of any person examined, or aid in so doing, or who shall furnish to any person any special or secret information for the purpose of either improving or injuring the prospects of any person so examined being appointed, employed, or promoted. It was provided that after six months from the passing of the act, no officer or clerk was to be appointed until after passing examination, unless specially exempted by the act; and no person in the habit of using intoxicating beverages to excess is to be appointed to or retained in any office, appointment, or employment to which the act applies. This and subsequent legislation has wrought a wonderful change for the better, lessened the number of incompetent politicians who thrive upon the 'spoils system' applying for office, and secures a far better class of public servants in all departments of the government.

Civita' Castellana, a town of Central Italy, 25 miles N. of Rome by the old Flaminian Road, on a plateau of volcanic tufa above the Treja. It has a handsome cathedral (1210), and a citadel built under Alexander VI., now a state-prison. Pop. 4251. In the neighbourhood are remains of the Etruscan *Federii*.

Civita' Vecchia, an Italian fortified port, 50 miles NW. of Rome by rail, on the Mediterranean. The harbour is both a commercial and naval one, and was originally constructed by the Emperor Trajan; the town indeed owed its origin entirely to the port of this emperor, and hence came to be known as *Portus Trajani*. Pop. (1881) 11,980. The harbour is formed by two moles and a breakwater, on which latter is a lighthouse. The place, which became a free port under Pope Innocent XII. in 1696, is regularly visited by steam-packets from Marseilles, Genoa, Leghorn, Naples, Messina, and Malta. It suffered at the hands of Goths and Saracens, and was occupied by the French in 1849. The papal troops opened the gates of the fortress to the Italian general Bixio in 1870.

Clackmannan, the county town of Clackmannanshire, on the Devon, 2 miles E. by S. of Alloa. An eminence rising 100 feet above the Forth is crowned by the ruined tower of the Bruces; and there are also an old market-cross, three churches, and a public hall. Pop. 1503.

Clackmannanshire, the smallest county of Scotland, lies between the counties of Perth, Fife, and Stirling, and slopes from the green Ochil Hills to the Forth. Its greatest length is 10 miles; area, 38 sq. m. Pop. (1871) 23,747; (1881) 25,677. A ridge of high ground, with inferior soil, often resting on clay, runs west through the middle of Clackmannanshire, between the very fertile alluvial lands resting on the coal-measures in the south, and the North Devon valley in the north. The 'Hillfoots' have long been celebrated for their woollen manufactures; ale and glass bottles are largely produced, and there is a trade in iron and shipbuilding. Clackmannan is the county town, but Alloa is the most important place. Clackmannanshire, with Kinross-shire, returns one member to parliament; anomalously it has parishes within its circumference politically—Alva in Stirlingshire, and Tulliallan and Culross in Perthshire—which it does not embrace judicially. See Beveridge, *Between the Forth and the Ochils* (1888).

Cladium, a genus of Cyperaceæ, of which one species, *C. Mariscus*, is a native of bogs and marshes in Britain, particularly in Cambridgeshire. Its habit is to grow in large masses, but these by no means occur frequently. It is rough-edged, and is consequently hurtful to cattle, but it is used for thatching.

Clairborne Group, a name given in America to certain beds of clay, lignite, shelly sands, and marly limestone which occur at Clairborne, Alabama, and are believed to belong to the Eocene system.

Clairac, a town in the French department of Lot-et-Garonne, on the Lot, 18 miles NW. of Agen. Here fine white wines are made. Pop. 2197.

Clairaut, ALEXIS CLAUDE, mathematician, was born at Paris, 13th May 1713. He early exhibited a most remarkable aptitude for mathematics, and was considered worthy of admission to the Academy of Sciences when only eighteen years of age. Clairaut wrote a great number of scientific papers, but his fame rests principally upon his *Théorie de la Figure de la Terre* (1743), in which he promulgated the theorem that the variation of gravity on the surface of the earth, regarded as an elliptic spheroid, was altogether independent of the law of density; on his explanation of the motion of the lunar apogee, a point left unexplained by Newton; and on his computation of the time of the return of Halley's comet. He died at Paris, May 17, 1765.

Clairvaux, a village of France, on the Aube, 10 miles SE. of Bar-sur-Aube, is remarkable as the site of the once famous Cistercian abbey, founded in 1115 by St Bernard, who presided over it till his death in 1153, when he was buried in the church. The unwholesome swampy valley became the smiling *Clara Vallis* under the efforts of the monks, who at Bernard's death numbered 700; afterwards the founder's ascetic rule was disregarded, and the simple row of cells gave place to a palatial monastery, whose church was reckoned a masterpiece of architecture, but was destroyed at the Restoration. The abbey, which at one time possessed a revenue of 120,000 livres, had been suppressed at the Revolution, and the extensive buildings are now used as a central prison for the thirteen eastern departments of France.

Clairvoyance, the faculty, attributed to persons in the mesmeric state, of seeing objects not present to the bodily senses, whereby the clairvoyant is enabled to describe events passing at a distance. For the scientific estimate of such claims, see ANIMAL MAGNETISM. The simple

clairvoyance of the professional entertainer is easily effected with the assistance of a code of signals and a good memory; generally the subject is blindfolded on the stage, while a confederate passing among the audience holds up the objects offered to him, and requires them to be named.

Clam is the common name for bivalves of the genus *Chama* (q.v.) and some other allied genera. The common clam, or soft clam of northern waters, is the *Mya arenaria*, or *Chama arenaria*; it is found especially in gravelly mud, sand, and other soft bottoms, especially between high and low water mark. They are largely used for bait, and in New England are a much relished article of food. Some kinds of clams rival oysters in popularity in New York. The hard clam, or Quahang, is the *Venus mercenaria*. The Giant Clam, the *Tridacna Gigas*, found in East Indian waters, in lagoons, and on coral islands, is of enormous size, the animal (which is edible) without the shell weighing 20 lb., while with the shell it may weigh 500 lb. The shells are used as ornaments for grottoes and fountains, and as bénitiers in Catholic churches.—The BEAR'S PAW CLAM is the *Hippopus maculatus*, a bivalve mollusc of the Indian Ocean, of the family Tridacnidae. The shell is one of the most beautiful of bivalves, alike in form, texture, and colour. It is a favourite shell for ornamental purposes. The margins of the valves are locked together by closely fitting teeth. It is 6 by 10 inches in length, broad in proportion, and transversed by ribs which are roughened by scale-like inequalities. The general colour is white, but there are beautiful spots of purplish-red.

Clan (Gael. *clann*, Manx *cluan*, meaning 'children,' i.e. descendants of a common ancestor). This word became incorporated with the English language at least as early as the 17th century, to mean a body of men confederated together by common ancestry or any other tie, and in this sense it is used both by Milton and Dryden. It came to be applied almost exclusively to the several communities of the Scottish Highlanders, as divided from each other topographically and by distinctive surnames. The word has sometimes been applied to those great Irish septs which at one time were a sort of separate states; but these, with their characteristic forms of internal government, were completely broken down by the power of the English predominance, before the word came into familiar use in the English language. In Scotland it was used in the 16th century to designate the freebooters of the Border as well as the Celtic tribes of the Highlands; and there were two characteristics common to both—their predatory habits, and their distribution into communities. The assumption of a common surname was general, but by no means universal. Men of the most various origin were in the habit of enlisting under chiefs as men now enlist in a regiment. Very often they took the chief's name, but very often they did not. It was essentially a military organisation for defensive and predatory purposes; and the adoption of a common name became a mere survival which kept up the idea and theory of patriarchal times long after the old tribal system had in all its essentials disappeared. In the Act of the Scottish parliament of 1587, for instance, which requires landlords to find security for the conduct of their tenants, it is provided that those 'who have their lands lying in far highlands or borders, they making residence themselves in the inlands, and their tenants and inhabitants of their lands being of clans, or dependants on chieftains or the captains of the clans, whom the landlords are noways able to command, but only get their mails (or rents) of them, and no other service or obedience, shall noways be subject

to this act but in manner following.' Then follow provisions for enforcing the law directly on the chieftains or captains of those clans residing in territories where the owner of the soil—generally the merely nominal owner, in terms of some useless charter—had no control. It was always the policy of the old law of Scotland to require all the Highland clans to have some respectable representative—a man of rank and substance, if possible—who should be security at court for their good conduct. Clans that could find no security were called 'broken clans,' and their members were outlaws, who might be hunted down like wild beasts. The Macgregors were a celebrated broken clan, whom the law pursued for centuries with savage ingenuity. Among other inflictions their name was proscribed, and such members of the clan as endeavoured to live by peaceful industry in the Lowlands adopted derivations from it; hence we have the names of Gregor, Gregory, and Gregorson or Grierson.

The clans are never treated in the old Scots acts with any respect, or otherwise than as nests of thieves and cut-throats. The following passage in the Act of 1581 (chap. 112), which virtually authorises any Lowlander, injured by any member of a clan, to take vengeance against all or any of his clansmen, contains a picturesque and striking account by men who knew and had suffered from the system of the Highland clans in the 16th century. 'The saids clans of thieves for the most part are companies of wicked men, coupled in wickedness by occasion of their surnames or new dwellings together, or through keeping society in theft or receipt of theft, not subjected to the ordinar course of justice, nor to any one landlord that will make them answerable to the laws, but commonly dwelling on sundry men's lands against the good-will of their landlords, wherethrough true men oppressed by them can have no remeid at the hands of their masters, but for their defence are oftentimes constrained to seek redress of their skaiths of the hail clan, or such of them as they happen to apprehend. Likewise the hail clan commonly bears feud for the hurt received by any member thereof, whether by execution of laws, or order of justice, or otherwise.' The Highland clans are often spoken of as a feudal institution, and it is undoubtedly true that 'broken men' were settled upon lands in possession of the chiefs on conditions of military service, just as under the more perfected system of Norman feudalism. The men receiving admission into 'rooms,' or small barns, were in the habit of binding themselves to such service by what was called 'Bonds of Manrent,' under which they engaged to follow their chief in all his feuds and quarrels. But, on the other hand, chiefship might become, and did often become, dissociated from the legal ownership of land, and in such cases the people of the clan were apt to follow their chief, against the will of their landlords. This was the survival of a far more remote system which constituted the great danger and great corruption of the clans. It dissociated the military power of chiefship from the responsibilities of property, and from subordination to settled law. This was the evil struck at and denounced by the parliament of Scotland in repeated statutes. In general the great landowners were also great chiefs, and the two powers then worked in harmony, and on the whole in the interests of civilisation under very rude conditions of society. But the severance arose not unfrequently from the more definite laws and rules applicable to the legal descent of landed property. Thus it came about, as the acts above quoted explain, that the head of a clan and the owner, according to feudal law, of the estates occupied by it, were two different persons. Clans did not acknowledge the purely feudal hereditary principle,

and occasionally would recognise the chiefship in a brother or an uncle, in preference to the son of a deceased chief. See **TRIBE**.

Clandestine Marriage. See **MARRIAGE**.

Clanwilliam, a division of the Western Province, N. of Cape Town, South Africa, embraces within its area the rich valley of Olifant River West, with a large stretch of mountain and karroo on each side. Chief village, Clanwilliam on Jan Dissels River.

Claparède, EDOUARD, a Swiss naturalist and professor of Comparative Anatomy at Geneva, was born in 1832, and died in 1871. He wrote numerous works, including those on the fertilisation of eggs (1858), on the Infusoria and Rhizopoda (1860), and the Annelida of the Hebrides (1861).

Clapham is a south-western suburb of London, lying a mile S. of the Thames. Battersea and Clapham form since 1885 one of the London parliamentary boroughs. Clapham Common is still an open common of 200 acres. Clapham Junction, in Battersea parish, is one of the busiest and most perplexing railway junctions in the world.—*Clapham Sect* was a name given by Sydney Smith to the Evangelical party in the Church of England; the Rev. Henry Venn was the vicar of Clapham, and some of the most eminent Evangelicals—Zachary Macaulay, Wilberforce, and the Rev. W. Romaine—lived there. Thackeray's *Newcomes* has made the phrase familiar to a later generation.

Clapperton, HUGH, African explorer, was born at Annan, Dumfriesshire, in 1788. At the age of thirteen he went to sea; and having after a youthful peccadillo been constrained to join a man-of-war, he ultimately distinguished himself by his services at Mauritius, and was appointed to the rank of lieutenant. In 1817 he returned to England on half-pay. Government appointed him and Lieutenant Denham to accompany Oudney, who was going as British consul to Bornu, in an exploring expedition. By way of Tripoli and Murzuk, they reached Kuka on Lake Tielad in 1822; and Clapperton proceeded westward, accompanied by Oudney, who died by the way. He still pushed on alone as far as Sokoto, but was here compelled to retrace his steps, and, in company with Denham, returned to England in 1825. The journey had done much for the knowledge of Bornu and the Houssa country, but the great geographical problem of the course of the Niger was still much in the same position. To solve it, if possible, Clapperton—the rank of commander having been conferred upon him—started again in August 1825, in company with Captain Pearce, R.N., Mr Dickson, Dr Morrison, and Richard Lander. They commenced their exploration into the interior from the Bight of Benin. His other companions died early on the journey, but Clapperton and his faithful attendant Lander reached Sokoto. Here the Sultan detained him, and vexation joined to the hardships of the journey so affected his health, that he died at Changary, near Sokoto, April 13, 1827. See the *Narrative of the first journey (1826)*; the *Journal of the second (1829)*; and the *Records of Clapperton's Last Expedition to Africa*, by Richard Lander (1830).

Claque (from Fr. *claquer*, 'to clap the hands,' or 'applaud') is the name given to an institution for securing the success of a public performance or production, by bestowing upon it preconceived applause, and thus giving the public, who are not in the secret, a false notion of the impression it has made. The claque is of great antiquity, its first invention having been attributed to no less

noted a person than Nero. Its supposed origin in Rome gives the name of *Romains* to the *claqueurs* to this day, who are also named *chevaliers du lustre*, from their position in the middle of the pit. The first regular use of the claque as an organised and paid body seems to have been during the time of the great Napoleon, in the famous struggle between Mademoiselle Georges and Mademoiselle Duchesnois, at the Théâtre Français; and from that time its use became almost universal in Paris. The chief of the claque, who is named *entrepreneur de succès dramatique*, is an official of importance. His business is to attend the last two or three rehearsals of a new play; to arrange the points at which applause, laughter, or tears are to be forthcoming; and to communicate his directions to his *corps*. This is divided into several classes. The main body, whose business it is to applaud, form a solid mass in the centre of the pit; and in various parts of the theatre are placed *ricurs* ('laughers'), *pleureurs*, or rather *pleureuses* ('weepers'), and *bisseurs* (whose business it is to call *bis* or *encore*). More artistic developments of the *claqueur* are the *sanglotteuse*, a female who sobs hysterically; the *pâméeuse*, who faints; and the *moucheur*, a well-dressed gentleman who blows his nose with tact at affecting passages.

The members of the claque are generally men who are glad to earn a small sum in any way, but it is also recruited from the ranks of poor *amateurs*, who in return pay a smaller price for their tickets. M. Perrin, the late director of the Théâtre Français, succeeded in 1878 in abolishing the claque in his theatre; and the Grand Opéra followed the example of the house of Molière.

In London there is no regularly organised claque, but in certain theatres precautions are taken on first nights which have precisely the same effect as the claque.

Clare, a maritime county in the province of Munster, Ireland, lying between Galway Bay and the Shannon. It is seventh in size of the Irish counties; length, 67 miles; greatest breadth, 43; average, 21; area, 1294 sq. m.—The surface is mostly hilly, with some mountains, bog, marsh, and rugged pasture. There is an undulating plain in the centre, from north to south. In the east the hills reach a height of 1758 feet. The sea-line is high and rocky, in parts precipitous, and occasionally from 400 to 680 feet high, with many isles and fantastic detached rocks. The chief rivers are the Shannon (q.v.) and the Fergus, running south 27 miles through the middle plain, and by an estuary 5 miles broad. The county has about 100 small lakes. Carboniferous limestone is a prevailing formation; the south-west third of the county forms part of the Munster coal-field. There are lead-mines, slate and marble quarries, and many chalybeate springs. The chief crops are oats and potatoes. The chief towns are Ennis (the county town), Kilrush, Ennistimon, and Killaloe. Pop. (1841) 286,394; (1851) 212,428; (1871) 147,864; (1881) 141,457, of whom nearly 98 per cent. were Roman Catholics. The county returns two members to parliament. There are many cromlechs, raths, remains of abbeys, and old castles or towers, and several round towers, one at Kilrush being 120 feet high. Till the time of Elizabeth the county was called Thomond; its present name comes from an English adventurer, Thomas de Clare, who received from Henry III. a part of all the land he might conquer from the Irish.

Clare, one of the most interesting of the smaller towns of Suffolk, 68 miles N.E. of London by rail, and 19 SSW. of Bury. Pop. (1881) 1704. It has a fine old castle, and gives an earl's title to the British sovereign. See **CLARENCE**.

Clare Island, an island of Ireland, belonging to County Mayo, situated in the Atlantic, at the entrance of Clew Bay. It has a length of 5 miles, with a breadth of 3 miles. On its north-east extremity there is a lighthouse.

Clare, JOHN, English peasant poet, the son of a poor labourer, was born at Helpstone, near Peterborough, July 13, 1793. After some scanty schooling, he began to do outdoor work in his seventh year, and for eleven months was an under-gardener at Burghley Park; meanwhile he studied Thomson's *Seasons*, and began to cultivate verse-writing. He enlisted in the militia (1812), associated with gypsies, in 1817 worked at a lime-kiln, but was discharged for wasting his time in scribbling, and had to apply for parish relief. His *Poems, descriptive of Rural Life and Scenery* (1821), had a good reception from critics and the public. Though the Marquis of Exeter and other patrons secured him £45 a year, he continued poor and unfortunate. His *Shepherd's Calendar* (1827) was unsuccessful. His *Rural Muse* (1835) brought him £40, and he received £50 from the Literary Fund. Broken down in body and mind, he died in the county lunatic asylum, Northampton, 20th May 1864. See Martin's *Life* (1865), and Cherry's *Life and Remains* (1873).

Clare, ST, born in 1193, of a noble family of Assisi, in 1212 retired to the Portiuncula of St Francis, and in the same year founded the order of Franciscan nuns, which spread rapidly through Europe. She died August 11, 1253. Two years afterwards, she was canonised by Alexander IV.; her festival falls on August 12.—The *Nuns of the Order of St Clara* (also called the Poor Clares) at first observed the strictest Benedictine rule, but the austerity of this rule was mitigated by St Francis in 1224, and further modified by Urban IV. in 1265. Several convents adhered to the first and strictest rule; but the large proportion of the nuns adopted Urban's rule, and are distinguished as *Urbanists*. The existing convents are chiefly devoted to the education of girls.

Claremont, a mansion at Esher, Surrey, 14½ miles SW. of London, originally built for himself by Sir John Vanbrugh. The present house was built in 1768 by Lord Clive for £100,000, from designs by 'Capability' Brown. When the Princess Charlotte was married to Prince Leopold of Saxe-Coburg, Claremont was assigned as their residence, and here in 1817 she died. In 1848 Leopold, then king of Belgium, placed it at the disposal of his father-in-law, ex-king Louis-Philippe, who inhabited it till his death in August 1850. At the death of Leopold in 1865, an act was passed granting it to the Queen for life, after which it was to revert to the country. The Queen in 1882 bought the reversion of Claremont (for £73,000), and it became her private property.

Clarence, an English ducal title, conferred for the first time in 1362 on Lionel, second son of Edward III. and Philippa. Its origin has by some been traced to Clarence, a French name of the Greek *Klarenza* or *Glarentsa* (Ital. *Chiarenza*), a decayed port on the west coast of the Peloponnesus, 50 miles SW. of Patras. Before the invasion of the Turks it was an important place, and gave the title of duke to the eldest son of the prince of Achaia. That title is said to have come into England through Philippa, daughter of the Count of Hainault, and wife of Edward III. Other authorities derive it from the ancient Suffolk town of Clare (q.v.). The most notable Dukes of Clarence, all royal, are the second son of Henry IV., who fell at the battle of Beaugé (1421); the third son of Richard of York, and brother of King Edward IV. (Shake-

peare's Clarence), who perished in the Tower in 1478—in a butt of Malmsey, according to an unsupported tradition; and William IV., who was Duke of Clarence before his accession.

Clarenceux, or CLARENCIEUX, the first of the two provincial Kings-of-Arms, in England, whose jurisdiction of Clarenceux extends to all England south of the Trent, that of Norroy (q.v.) comprehending the portion north of that river. The title is said to be derived from the Duke of Clarence, third son of King Edward III. See HERALD.

Clarendon, CONSTITUTIONS OF, were laws made by a council of the nobility and prelates held at the hunting lodge of Clarendon, 2 miles SE. of Salisbury, in 1164, whereby King Henry II. checked the power of the church, and greatly narrowed the total exemption which the clergy had claimed from the jurisdiction of the secular magistrate. These famous ordinances, sixteen in number, defined the limits of the patronage, as well as of the jurisdiction, of the pope in England, and provided that the crown should be entitled to interfere in the election to all vacant offices and dignities in the church. The constitutions were unanimously adopted, and Becket, the primate, reluctantly signed them. His subsequent withdrawal of his consent, when Pope Alexander III. declined to ratify them, led to the memorable disputes between Becket and the king (see BECKET). Notwithstanding the personal humiliation to which Henry submitted after Becket's death, most of the provisions of the constitutions of Clarendon, which were part of a great scheme of administrative reform, continued to be a permanent gain to the civil power. See Stubbs, *Constitutional History*, and his *Select Charters*.

Clarendon, EDWARD HYDE, EARL OF, historian and statesman, was born 18th February 1608 at Dinton, near Salisbury, the third son of a Wiltshire squire. Destined for the church, he went up to Magdalen Hall in 1622; but the death of his elder brothers left him heir to the property, so in 1625 he quitted Oxford for the Middle Temple, of which his uncle, Sir Nicholas Hyde, the chief-justice, then was treasurer. Though he rose in his profession, he loved letters better than law; for his friends he chose such brilliant spirits as Falkland, Ben Jonson, and Chillingworth, and, in his own words, 'was never so proud, or thought himself so good a man, as when he was the worst in the company.' He married twice—in 1629, Ann, daughter of Sir George Ayliffe, whose death six months afterwards 'shook all the frame of his resolutions'; next, in 1632, Frances, daughter of Sir Thomas Aylesbury, Master of Requests and of the Mint. She bore him four sons and two daughters; and with her, till her death in 1667, he 'lived very comfortably in the most uncomfortable times, and very joyfully in those times when matter of joy was administered.'

In 1640 he was returned for Wootton-Bassett to the Short Parliament, for Saltash to the Long; and up to the summer of 1641 he acted heartily with the popular party. Then he drew back. Enough, he deemed, had been done; a victorious oligarchy might prove more formidable than a humbled king; nor could he conceive 'a religion without bishops.' Charles's answer to the Grand Remonstrance was of Hyde's composing, so were most of the subsequent able manifestoes; and though in a midnight interview with the king he declined to take St John's post of solicitor-general, thenceforward, with Falkland and Colepeper, he formed a veritable privy-council. If only they had known everything, if only their advice had always been followed! but no, the attempted arrest of the five members had neither their privacy nor their approval. Still, Hyde headed the royalist opposition

in the Commons, till, in May 1642, he slipped away, and followed Charles into Yorkshire. He witnessed Edgehill; in 1643 was knighted, and made Chancellor of the Exchequer; in March 1645 attended the Prince of Wales to the west of England; and with him a twelvemonth later passed on to Scilly and Jersey. In Scilly, on 18th May 1646, he commenced his history; in Jersey he tarried two whole years. From November 1649 till March 1651 he was engaged in a fruitless embassy to Spain; next for nine years he filled the office of a 'Caleb Balderstone' in the needy, greedy, factious little court of Charles II., sometimes with 'neither clothes nor fire to preserve him from the sharpness of the season, and with not three sous in the world to buy a fagot.'

Charles had made him High Chancellor in 1658, and at the Restoration he was confirmed in that dignity, in November 1660 being created Baron Hyde, and in the following April Earl of Clarendon. To this period belongs the strangest episode in all his autobiography. In November 1659 his daughter Anne (1638-71), then lady-in-waiting to the Princess of Orange, had entered into a secret marriage-contract with the king's brother, James, Duke of York; and nine months later they were privately married at her father's house. He, on learning the news, if news indeed it was, burst into a passion of the coarsest invective against her—it were more charitable to suppose he was acting a part, not really less jealous for his daughter's honour than for the dignity of the royal house. Anyhow, people fancied that in Catherine of Braganza he purposely selected a barren bride for the king, that so his own daughter might some day come to the throne. Nor as chief minister was he otherwise popular. A bigoted churchman, a thorough Conservative, and always a lawyer, he would fain have restored things to the *status quo* of twenty years earlier. He loved a Papist little better than a sectary, so would have nought of Charles's toleration. He looked sourly on Charles's vices, yet stooped to impose Charles's mistress on Charles's queen. He could not satisfy the Cavaliers, who contrasted his opulence with their own broken fortunes; he did more than enough to irritate the Puritans. The sale of Dunkirk, the Dutch war, the very Plague and Great Fire, all heightened his unpopularity; and though in 1663 he weathered Lord Bristol's frivolous charges against him, in August 1667 he fell an easy unlamented victim to a court cabal. The great seal was taken from him; impeachment of high-treason followed; and on 29th November, at Charles's bidding, he quitted the kingdom for France. All but murdered at Evreux by some English seamen, at last the old man settled at Montpellier, where and at Moulins he spent nearly six tranquil years. Then moving to Rouen, he sent a last piteous entreaty that Charles would permit him to 'die in his own country and among his own children'; nay, at Rouen must he die, on 9th December 1674. No monument marks his grave in Westminster Abbey.

Men's estimates of Clarendon have varied widely. Southey calls him 'the wisest, most upright of statesmen'; George Brodie, 'a miserable sycophant and canting hypocrite.' The truth lies somewhere between the two verdicts, but Southey's is much the truer of the two. The failings and merits of the statesman are mirrored in his great *History of the Rebellion in England* (3 vols. 1704-7), with its supplement and continuation, more faulty and less valuable—the *History of the Civil War in Ireland* (1721), and the *Life of Edward, Earl of Clarendon* (3 vols. 1759). An apology more than a history, a vindication of himself and of Charles I., it is not, does not profess to be, impartial; it suppresses the truth, where the truth seemed unfavourable; and

it is grossly inaccurate—the result of a fallible memory. But, Mr Green notwithstanding, it does not 'by deliberate and malignant falsehood' pervert the whole action of Clarendon's adversaries; careless and ungenerous he might be, wilfully dishonest he was not. And what though his style be prolix and redundant, though it 'suffocate us by the length of its periods,' his splendid stateliness, his anecdotic talent, his development of motives, and, above all, his marvellous skill in portraiture (shown best in the character of his dear friend Falkland), have rendered the history a classic, imperishable where dry-as-dust chronicles have perished. The best and latest edition is that by W. Dunn Macray (6 vols. Oxford, Clarendon Press, 1880). We have, besides, twenty-five essays by Clarendon, his *Contemplations on the Psalms* (begun in 1647, and finished, like the *Life*, during his second exile), several controversial writings, and 3 vols. of his *State Papers* (1767-86; calendared, 1872-76).

See Ranke's able analysis of the *History*; works cited under CHARLES I. and CHARLES II.; the Hon. Agar-Ellis's *Historical Inquiry respecting the Character of Clarendon* (1827); Lady Theresa Lewis's *Lives of the Friends and Contemporaries of Clarendon* (3 vols. 1852); two articles by Mr Peter Bayne in the *Contemporary Review* (1876); and the *Life of Clarendon*, by T. H. Lister (3 vols. 1838).

Clarendon, GEORGE WILLIAM FREDERICK VILLIERS, EARL OF, a great English diplomatist, was born in London, 12th January 1800. He was a descendant of that Thomas Villiers, second son of the Earl of Jersey, who married the heiress of the last Lord Clarendon of the Hyde family (1752), and was made Baron Hyde (1756) and Earl of Clarendon (1776). Having studied at Cambridge, he early entered the diplomatic service, and in 1833 was appointed ambassador at Madrid, where he acquired great influence, which he employed in helping Espartero to establish the government of Spain on a constitutional basis. On the death of his uncle, the third earl of the second creation, without issue, in 1838, he succeeded to the title, and in 1840 was made Lord Privy Seal under Melbourne. When the Whig ministry was broken up in 1841 he became an active member of the opposition; but warmly supported Sir Robert Peel and his own brother, Charles Pelham Villiers, in the agitation for the abolition of the corn laws. Under Lord John Russell's premiership he became President of the Board of Trade in 1846, and the following year was appointed Lord-lieutenant of Ireland. He entered upon his duties in troublous times. The insurrectionary follies of Smith O'Brien and his coadjutors might have set the whole country in a blaze but for the prompt and decisive measures which the new viceroy adopted, and which soon restored general tranquillity. At the same time, his tact and impartiality contributed to allay and reconcile the exasperations of party, though it did not avert the bitter hatred of the Orangemen. He was thanked in the speech from the throne in 1848, and next year received the coveted honour of the garter. When the Russell cabinet resigned in 1852, Clarendon was replaced by the Earl of Eglinton, but on the formation of the Aberdeen ministry next year was intrusted with the portfolio of the Foreign Office. It was thus upon his shoulders that the responsibility for the Crimean war actually fell. Mr Roebuck's resolution in 1855 cost him his office, which, however, he soon resumed at Palmerston's desire, and he sat at the Congress of Paris. Lord John Russell was Foreign Secretary from 1859 to 1865, but became Premier on Palmerston's death, when Clarendon returned to the Foreign Office. Next year he retired with his colleagues, to resume the same office in Gladstone's government in 1868,

which he retained till his death, 27th June 1870. Lord Clarendon was a man of singularly genial and charming manners, who added by his rare tact and perfect temper an unwonted grace to the difficulty and invidiousness of diplomacy.

Clarendon Press. See BOOK-TRADE.

Clarens, a beautiful Swiss village on the Lake of Geneva, 3½ miles SE. of Vevey by rail.

Claret (Fr. *clairet*), a term originally applied to wines of a light-red colour, but which is now used in England as a general name for the red wines of Bordeaux (q.v.). The name as used in England is unknown in France.

Claretie, JULES (properly ARSÈNE ARNAUD), a versatile French writer and popular novelist, born at Limoges, 31 December 1840. While still a schoolboy at the Lycée Bonaparte in Paris, he published a novel, and ere long his facile and clever pen made him one of the most important art and dramatic critics and political writers on the Paris press. His short story *Pierrille* (1863) had the honour to be praised by George Sand; and his novels, *Mademoiselle Cochemire* (1865), and *Un Assassin*, renamed later *Robert Burat* (1866), gained general applause. Meantime he continued his career as a journalist, although he suffered sometimes from the imperial censorship. During the Franco-German war he sent a series of remarkable letters to the *Rappel* and *Opinion Nationale*, and acquired the materials for a later series of bright and vigorous anti-German books of an historical character: *Histoire de la Révolution de 1870-71* (new ed. 5 vols. 1875-76); *Les Prussiens chez Eux* (1872); and *Cinq Ans après, l'Alsace et la Lorraine depuis l'Annexion* (1876). He distinguished himself by his conduct during the siege of Paris, and showed that he possessed also high talent for affairs. His more important later novels are *Madeleine Bertin* (1868); *Le Train 17* (1877); *Monsieur le Ministre*, an enormous success (1881); *Le Million* (1882); *Michel Berthier* (1883); and *Le Prince Zilah* (1884). He first found a firm footing on the stage with his pictures of the great Revolution, *Les Muscadins* (1874), *Le Régiment de Champagne* (1877), and *Les Mirabeau* (1878); and in 1885 he succeeded M. Perrin as Director of the Théâtre Français. An English translation of his *Life of Camille Desmoulins* was published in 1876.

Clarification is the process of clearing a fluid from a turbid condition, as in the case of Beer (q.v.), or in the action of gelatin in fining British wines. Natural waters containing much organic matter in mechanical suspension and in chemical solution are clarified by the addition of a little alum, which is precipitated with the organic matter, and the water then becomes healthy and refreshing. Liquids are often clarified by straining through several layers of cloth, or through sand or charcoal. The use of the Clearing Nut (q.v.) for clarifying water is general in India. A very interesting and useful method of clarification is that in which a 'centrifugal' is employed. This consists of a circular vessel provided with an outlet in the centre and also at the circumference, and which is so constructed as to be capable of being made to revolve at a very high speed. When the muddy liquid is placed in the vessel, and the whole caused to revolve, it is found that the particles of dust, mud, or other matter fly to the circumference, leaving the liquid in the centre practically clear. By suitable arrangements the clear liquid can be drawn off.

Clarinet, or CLARINET, a wind-instrument, usually of wood, in which the sound is produced by a single thin reed. It is supposed to have been invented in 1690 by Joseph Christoph Denner, at Nuremberg, though some authorities trace its exist-

ence to medieval times. Since its invention it has undergone many changes and improvements, and the modern clarinet, from the extent, quality, and variety of its tone, is one of the most perfect of wind-instruments. The tube of the instrument is cylindrical, ending in a bell, with holes to be covered by the fingers and left-hand thumb; and keys, generally thirteen in number, to supply the additional tones and half-tones.

The mouthpiece is cone-shaped, flattened on one side to form a table for the reed; in the table is a square opening about an inch long and half an inch wide (*a* in fig.), on which the reed is fastened by the lower and thicker end (*b* in fig.). The table being slightly curved towards the point, a gap is left between the end of the reed and the mouthpiece; and the sound depends on the vibration of the reed against this curved table. The reed is a thin slip from a tall grass (*Arundo sativa*) grown in Spain. The clarinet has two principal registers—viz. the lower, called the chalumeau, from *C* in the bass stave to *B♭* in the treble; and the upper, of a different quality, from *B♭* treble stave to *C* above the stave. Another octave higher can be played by cross-fingering, but beyond *G* the notes are not very effective. The difference between the lower and upper registers is an interval of a twelfth, which gives the clarinet a much greater compass than the flute, for instance, which is an octave-scaled instrument. The upper register is fingered exactly like the lower, except that the *B♭* key (the highest on the tube, *c* in fig.) is kept open by the thumb of the left hand. The Boehm modification of fingering (see FLUTE) has been applied to the clarinet, but is not so suitable to it as to octave-scaled instruments.

The ordinary difficulties of the fingering are so much intensified in playing in keys with many sharps or flats, that in orchestras it is usual to have instruments of different pitch to simplify the key. These are usually the *A*, *B♭*, and *C* clarinets, though the latter is gradually going out of use.

In military reed-bands the *B♭* clarinet is the leading instrument, with the addition of one or two smaller clarinets in *E♭* to assist in the sharper passages (see BAND). Clarinets in various other keys have been introduced but seldom used.

Mozart, Beethoven, Mendelssohn, Weber, Meyerbeer, Spohr, and Rossini have made extensive use of the clarinet in the orchestral compositions, though some of the parts written for the instrument, especially in the overtures to *Semiramide*, *Otello*, and *Gazza Ladra* by Rossini, are so difficult as to be almost unplayable.

A tenor clarinet, known as the Bass-Horn (q.v.), is also used in orchestral music. The Bass Clarinet is an instrument of the same construction as the ordinary clarinet, an octave lower, usually pitched in *B♭*. It is also used in orchestral and military bands.

Clark, SIR ANDREW, a distinguished physician, was born at Aberdeen, 28th October 1826, and educated at Aberdeen and Edinburgh. After an unusually brilliant career as a student of medicine at Edinburgh, he assisted Dr Hughes Bennett and Dr Robert Knox the anatomist, and next had charge

Clarinet:

a, mouthpiece, back view, with reed removed; *b*, the same with reed attached.

for four years of the pathological department at the Haslar Naval Hospital. After graduating at Aberdeen in 1854, he settled in London, where he acquired a high reputation for his skill in the treatment of diseases affecting the respiratory, renal, and digestive organs. Among his patients were some of the most eminent men in the political and literary world of his time, and he will live in remembrance as the 'beloved physician' of George Eliot. He is President of the Royal College of Physicians, Honorary Fellow of the Royal College of Physicians in Ireland, and Consulting Physician to the London Hospital; and is besides LL.D. of Edinburgh and Aberdeen, a Fellow of the Royal Society, and a baronet since 1883. His favourite work has been clinical teaching at the London Hospital, for which Holl painted his portrait, just finished before that artist's lamented death. Although his professional success has left him scant leisure for writing, he has made numerous important contributions to medical science, both in papers contributed to the special journals and in such books as *Evidences of the Arrestment of Phthisis*, *Lectures on the Anatomy of the Lung*, *The Theory of Asthma*, *The History of Dry Pleurisy in relation to Lung Disease*, *Renal Inadequacy*, *The Anæmia of Girls*, *Neurasthenia*, and *Mucous Diseases of the Colon*.

Clark, SIR JAMES, physician, was born at Cullen, Banffshire, 14th December 1788. He took the degree of M.A. at King's College, Aberdeen, studied medicine at Edinburgh and London, and entered as a navy surgeon in 1809—a position he held until 1815. At Rome he practised eight years as a physician; but in 1826 he settled in London. On the accession of Queen Victoria, Clark, who for two years previously had acted as physician to the Duchess of Kent, was appointed physician in ordinary to Her Majesty, in 1838 being created a baronet. He was author of a work *On the Influence of Climate in the Cure of Chronic Diseases* (1829), and *A Treatise on Pulmonary Consumption* (1835). He died June 29, 1870.

Clark, THOMAS, chemist, was born at Ayr in 1801, and studied at Ayr Academy. He became a chemist in Glasgow, lectured on chemistry there, and in 1833 became professor at Marischal College, Aberdeen. He fell into ill-health in 1843, and died 27th November 1867. His name is specially remembered for his discovery of the soap-test for hardness in waters, and his method of softening water by means of caustic lime. See WATER.

Clark, WILLIAM GEORGE, an eminent scholar and man of letters, was born in March 1821, and educated at Sedburgh and Shrewsbury under Kennedy. He entered Trinity College, Cambridge, in 1840, and, graduating second classic in 1844, was elected fellow of his college, where he resided till his retirement in 1873. He had been ordained in 1853, but wrote to his bishop resigning his orders in 1869, and published his reasons in a remarkable pamphlet, *The Present Dangers of the Church of England*. He acted long as tutor in his college, and was public orator in the university from 1857 to 1869. He died at York, 6th November 1878, bequeathing to Trinity College property to endow a lectureship on English literature, to which Mr Gosse was appointed in 1883. Clark travelled in Spain, Greece, Italy, and Poland, during the long vacations, and published lively accounts of his experiences. In 1850 he helped to edit the *Sabrinæ Corolla*, himself contributing some of the most finished versions therein. He also edited the first series of *Cambridge Essays* (1855), and long acted as one of the editors of the *Journal of Philology*. Other works were his edition of George Brinley's *Essays* (1858), and *Lec-*

tures on the Middle Ages and the Revival of Learning (1872). His greatest work was the famous *Cambridge Shakespeare* (9 vols. 1863-66), planned by Clark, and prepared in collaboration with Mr Glover and afterwards Mr Aldis Wright. Its text was reprinted in the popular 'Globe Edition' (1864). Clark's projected edition of Aristophanes was unhappily left unfinished.

Clarke, ADAM, Wesleyan divine, was born about 1762, at Moybeg in County Londonderry. Under John Wesley's influence he studied at Kingswood, near Bristol, and began to preach in 1782. Like his brethren, he moved from place to place, from the Channel Islands to Shetland, but after 1805 lived mostly in London. Although peripatetic preaching is scarcely conducive to scholarship, Clarke contrived to find time for extensive study of the classics, the Fathers, oriental languages, and natural science. Aberdeen gave him the degree of LL.D. in 1808, and many learned societies admitted him to membership. His first work was a *Bibliographical Dictionary* (8 vols. 1802-6). The Board of Commissioners on the Public Records selected him to edit Rymer's *Fœdera*, but his health obliged him to abandon the work before he had finished the second volume. He also edited and abridged several other works, but the great work of his life was his edition of the Holy Scriptures (8 vols. 1810-26) with a commentary, into which were compressed all the results of his varied reading. While orthodox in essentials, Clarke had some unusual notions. Thus, he denied the eternal sonship of Christ while maintaining his divinity; held that Judas repented unto salvation, and that the tempter of Eve was a baboon, not a serpent. He died August 26, 1832. See his *Life* (3 vols. 1833).

Clarke, CHARLES AND MARY COWDEN, one of the most amiable among the pairs of English writers. Charles was born 15th December 1787, at Enfield, Middlesex, where his father kept a school at which Keats was a pupil. His name is imperishably linked with the dawning genius of the poet—but seven years younger than himself—who in a poetical epistle (1816) addresses Clarke as 'you who first taught me all the sweets of song.' He early imbibed a passion for the theatre, and after his parents' retirement to Ramsgate, continued to pay frequent visits to London, where he formed the friendship of Leigh Hunt, Shelley, Hazlitt, Charles and Mary Lamb. After his father's death in 1820, he became a bookseller in London, and ere long partner as music publisher with Alfred Novello, whose sister, Mary Victoria (born 1809), he married in July 1828. A year later Mrs Cowden Clarke began her famous *Concordance to Shakespeare's Plays*, published after sixteen years' toil in 1845. The married life of the pair was exceptionally happy, and they enjoyed the warm friendship of most London men of letters, from Lamb and Hazlitt down to Douglas Jerrold, Macready, and Charles Dickens. In 1834 Clarke began that twenty years' course of public lectures on Shakespeare and other dramatists and poets which brought him so much celebrity and profit. He read admirably, and put the fruit of much sound study and profound thought into the preparation of the lectures. Some of his courses of lectures were published, as his *Shakespeare Characters, chiefly those Subordinate* (1863), and *Molière Characters* (1865). In 1859 he published *Carmina Minora*, a volume of fair original verse, and in 1863 he edited the poems of George Herbert. The joint productions of the pair were the valuable *Shakespeare Key* (1879); an edition of Shakespeare's works with good if somewhat verbose annotations (1869), now re-issued as *Cassell's Illustrated Shakespeare*; and *Recollections*

of *Writers* (1878), a charming and genial book, full of reminiscences of Keats, Lamb, and other famous men. In 1856 they went to live at Nice, but removed in 1861 to Genoa, where Charles died sixteen years later, 13th March 1877. Mrs Cowden Clarke alone wrote several novels, volumes of verse, and other works. Of these the best known are *The Girlhood of Shakespeare's Heroines* (1850), and *World-noted Women* (1857). See Mary Cowden Clarke's *Short Memoir of her Husband* (1887).

Clarke, EDWARD DANIEL, traveller and author, born at Willington in Sussex in 1769, studied at Cambridge, and from 1790 to 1799 was employed as tutor and travelling-companion in several noble-men's families, making the tour of Great Britain, France, Italy, Switzerland, and Germany. In 1799 he set out on an extensive tour with a young man of fortune; they traversed Denmark, Norway, Sweden, Lapland, Finland, Russia, the country of the Don-Cossacks, Tartary, Asia Minor, Syria, Egypt, Greece, and did not return to England till 1802. In 1807 Clarke began a course of lectures on mineralogy at Cambridge. He presented to the university library a number of valuable marbles collected during his travels; his manuscripts he sold to Oxford; and the university of Cambridge purchased his collection of minerals. Ordained in 1805, he held two livings from 1809 until his death, 9th March 1822. His *Travels* (6 vols. 1810-23) were received with extraordinary favour; his other works, chiefly on antiquarian subjects and mineralogy, are now of little value. See his *Life*, by Bishop Otter (1825).

Clarke, HYDE, an English financier and philologist, born in London in 1815, was employed as a civil engineer in the improvement of Morecambe Bay and Barrow, and next in the promotion of telegraph and railway service in Upper India. He became cotton councillor in Turkey, and in 1868 founded the Council of Foreign Bondholders, whose affairs he administered for some years. He has done much to promote the Anthropological Institute and the Press Fund. His writings include books and pamphlets on railways, foreign loans, banking, mythology, and comparative philology, especially the native American languages and their supposed connection with those of the Old World. Unfortunately his views are much more original than sound, and most of his generalisations have failed to commend themselves to really scientific philologists. Among his books are *The Pre-Hellenic Inhabitants of Asia Minor* (1864), *The Mediterranean Populations from Autonomous Coins* (1882), &c.

Clarke, JAMES FREEMAN, theologian, was born in Hanover, New Hampshire, and studied at Harvard and Cambridge Divinity School. He became a Unitarian pastor, and in 1841 founded the Church of the Disciples at Boston. From 1867 to 1871 he held a chair of Natural Theology in Harvard University. He died 8th June 1888. He assisted in preparing the memoirs of the Marchioness Ossoli; and among his numerous works are books on the forgiveness of sin, on prayer, and on orthodoxy, *Steps of Belief* (1870), *Ten Great Religions* (1871-83), *Common Sense in Religion* (1879), *Manual of Unitarian Belief* (1884), and *Vexed Questions* (1886).

Clarke, DR SAMUEL, an eminent philosopher and theologian, was born at Norwich, October 11, 1675, and educated at Caius College, Cambridge. The system of Descartes at that time held almost universal sway; but this failing to satisfy his mind, he adopted the views of his contemporary and friend Newton, and expounded them in the notes to his edition of Rohault's *Physics*. Along with philosophy he pursued the study of theology and philology. Chaplain from 1698 to Bishop Moore of Norwich, in 1706 he became chaplain to Queen

Anne, and in 1709 rector of St James's, Westminster. By his work on the Trinity (1712), in which he denied that that doctrine was held by the early church, he raised a violent and protracted controversy (in which Waterland was his chief opponent). The upper house of Convocation, desirous of avoiding controversy, rested content with an explanation, anything but satisfactory, and a promise from Clarke to be silent for the future on that subject. His views were of the kind known as *Semi-Arian* (see ARIUS). For the rest, Clarke was a vigorous antagonist of the Deists of his time; he wrote against materialism, empiricism, and necessitarianism; and against Dodwell maintained the essential immortality of the soul. He taught that the fundamental truths of morals, arising out of the fitness or unfitness of certain relations, were as absolutely certain as the truths of mathematics. Space and time he held to be attributes of an infinite and immaterial being. His most famous work is *Discourse concerning the Being and Attributes of God*, originally the Boyle Lectures of 1704-5. They were expressly in answer to Hobbes, Spinoza, Blount, and other freethinkers, and contained the famous and elaborate demonstration of the existence of God, often, but inaccurately, called an *a priori* argument, on which his fame as a theologian largely rests. At the instigation of the Princess of Wales, Clarke entered into a keen correspondence with Leibnitz on space and time, and their relations to God, and on moral freedom. This correspondence was published under the title of *Collection of Papers which passed between Dr Clarke and Mr Leibnitz* (1717). He was not merely a keen dialectician and a man of great strength of mind, but was possessed of great general ability. He published several collections of much admired sermons and innumerable pamphlets, besides a posthumous *Exposition of the Church Catechism* and a beautiful edition of Caesar (1712); that of Homer (1720-32) was completed by his son. He died 17th May 1729. A collected edition of his works appeared in 4 vols. (1738-42), with a *Life* by Hoadly. His friend Whiston also wrote a *Life* (1741).

Clarkson, THOMAS, philanthropist, the son of a clerical schoolmaster at Wisbeach, where he was born, March 28, 1760. From St Paul's School he passed to St John's College, Cambridge, where he took a good degree in 1783. His introduction to the chief interest of his life was his gaining a prize for a Latin essay in 1785, on the question, 'Is it right to make slaves of others against their will?' which, in an English translation (1786), was widely read. Clarkson henceforward devoted himself with indefatigable energy to a vigorous crusade against African slavery, both by an incessant shower of essays, pamphlets, and reports, and by visiting the chief towns of England and even Paris to form associations. Wilberforce brought the subject before parliament in 1787. On March 25, 1807, the law for the suppression of the slave-trade passed the legislature—the occasion of Wordsworth's sonnet: 'Clarkson, it was an obstinate hill to climb,' and Clarkson next wrote a *History of the Rise, Progress, and Accomplishment of the Abolition of the African Slave-trade* (2 vols. 1808). On the formation of the Anti-slavery Society in 1823, for the abolition of slavery in the West Indies, he became one of its leading members, and had the happiness to see the object of its efforts attained in the August of 1833. He took an active part in other benevolent schemes, particularly in establishing institutions for seamen in seaport towns similar to the Sailors' Homes. He was in deacon's orders in the Church of England, but all his life kept close to the Society of Friends, although he never joined its ranks. He died at Playford

Hall, near Ipswich, September 26, 1846. See *Lives* by Taylor (1839 and 1876) and Elmes (1854).

Clary (*Salvia sclarea*), a native of southern Europe, which has been cultivated from a very early period for its aromatic and other properties. It is a biennial (2 feet), with clammy stem, large, heart-shaped, rough, doubly crenate leaves, and whorls of pale-blue flowers in loose terminal spikes, with large coloured bracts. Clary is antispasmodic and stimulating, and is used for seasoning soups, and in confectionery, while a fermented wine is prepared from its flowers.—A British species of *Salvia* (*S. Verbenaca*) is sometimes called Wild Clary; *S. pratensis*, Meadow Clary; and *S. hornminum*, Annual Clary. See SAGE.

Classics. The term *classici* was originally applied to those citizens of Rome that belonged to the first and most influential of the six *classes* into which Servius Tullius divided the population. As early as the second century after Christ it is applied figuratively by Gellius to writers of the highest rank, and this mode of designation has since been very generally adopted both in literature and art. Most nations have had at some one time a more than usually rich and abundant outburst of literature, and they usually style this the *Classical* period of their literature, and its most distinguished writers their *Classics*. Thus, in Latin literature the classical period may be regarded as extending from the time of Varro, Cicero, and Lucretius, from about 80 B.C., to the time of Juvenal and Suetonius, about 180 A.D.; and is divided into a *Golden* and a *Silver Age*. But as the great productions of the writers and artists of antiquity have continued to be looked upon by moderns as models of perfection, the word *classics* has come to designate, in a narrower sense, the best writers of Greece and Rome, and 'classical' to mean much the same as 'ancient.' The question of the relative value in modern education of the study of the classics in this sense has been much discussed (see EDUCATION). For *Classicism* as opposed to *Romanticism*, see ROMANTICISM.

Clastic Rocks (Gr. *klastos*, 'broken') are rocks composed of fragmental materials. The term includes all rocks of a secondary or derivative origin—i.e. rocks like conglomerate, sandstone, shale, &c., which have been formed out of the remains of previously existing rocks. Besides the large class of *sand-and-gravel* rocks, it also embraces many rocks of organic origin, such as certain *Limestones* (q.v.), composed of the debris of shells, corals, &c.; *Coals* (q.v.), made up of the remains of plants; some *Ironstones* (q.v.), consisting in whole or in part of organic debris. Fragmental volcanic rocks, such as *Tuff* (q.v.) and *Agglomerate* (q.v.), come also into the same division.
